171, FLEET STREET.

## TO OUR READERS.

"IN wishing 'my friends and benefactors' the compliments of the season, I cannot exclude from amongst that class the Editors of the *Journal of Horticulture*, a paper that is inexpressibly dear to me, for from it I have derived profit and pleasure. Therefore permit me to tender to you my mite of thanks for the year that is about to pass away; and heartily do I hope, that in the new year which is about to open, your Journal may be appreciated still more and more by the horticultural world. Wishing happiness, long life, and prosperity to the *Journal of Horticulture* and its Editors, I am—A YOUNG GARDENER."

Such is one of the many greetings we have received; and as they have secured the aid that will render the Journal as useful and as trustworthy as in past years, the same hope as is expressed by "A YOUNG GARDENER" is entertained confidently by

THE OLD EDITORS.

Dec. 30th.

The first of these is the fact that the United States is a young nation. It is only about 150 years old, and its history is therefore a history of rapid growth and development. The second fact is that the United States is a large nation. It covers a vast area of land, and its population is one of the largest in the world. The third fact is that the United States is a diverse nation. It is made up of many different peoples, races, and religions, and this diversity has been one of its strengths.

The fourth fact is that the United States is a nation of immigrants. Many of the people who live in the United States today are the descendants of immigrants from other countries. This has helped to make the United States a more tolerant and accepting nation.

From observations taken near London during forty-three years, the average day temperature of the week is 74.8°; and its night temperature 50.3.

## PELARGONIUMS FOR CONSERVATORY DECORATION ALL THE YEAR ROUND.

THE perfection to which the Pelargonium of the common Tom Thumb type has now been brought renders this class of plants very suitable for indoor decoration. At the present time there are some signs of the old hardy sweet-scented flowers being substituted for the Geranium in many flower beds, and with the decadency of Geraniums for this purpose there is every appearance of their being used for conservatory decoration to a much greater extent than hitherto. Plants are not very plentiful which are capable of extending their flowering period over three or four months at the most, and it is pretty well known to those who are expected to have the conservatory replete with flowers every day of the year that it is often a difficult matter to keep up a gay appearance. With a quantity of selected and properly-managed Pelargoniums, however, every conservatory may be easily made a place of great beauty, not only at the change of the season, but throughout every day of the year.

Those introducing these Pelargoniums for the first time generally begin with young plants in 3-inch pots. This is the first size they are put into after they are rooted, and strong young plants produce fine trusses of bloom in this size for a time. As soon as the plants look as if they wanted more space at the roots to develop themselves they should be shifted into 6-inch pots. When placed in the 3-inch pots about the beginning of March they generally require to be shifted into the latter size about the latter end of May. The soil now, as at the first potting and all other times, should consist of somewhat open loam and a little thorough-decayed horse or cow dung. A small quantity of drainage carefully placed at the bottom of each pot is very necessary. As there is plenty of space to place a good quantity of fresh soil around a ball which is shifted out of a 3-inch pot into a 6-inch one without reducing the ball it should be transferred into the larger size whole. While potting, in every case, the soil should be pressed very firmly. When this is not done the plants must be watered two or three times a-day in hot weather. Some weeks after being placed in the 6-inch pots most of the plants will have made sufficient wood to afford a few cuttings. These should be taken off the first, second, or not later than the third, week of July. Each cutting should be made in the ordinary way and placed singly in small thumb-pots amongst a mixture of loam, leaf soil, and sand. Until they have formed a quantity of roots they must be kept in a cool rather moist place in a somewhat confined atmosphere. At this time of year they root quickly, and as soon as they begin to grow they should be potted into 3-inch pots and set in an open frame, or in the open air altogether if a frame is not available. From the time they begin to grow in the 3-inch pots until the middle of September they should be fully exposed to the sun, and never be

allowed to droop from want of water. Before that time many of the plants will show bloom, but every particle of this should be removed as it appears. In September each plant should be potted into a 6-inch pot. After this they should be grown in a frame where they can be protected from cold and wet, and all the flowers which are produced should be left on the plants after this time. In November this batch of plants will supply abundance of flowers, and continue to do so throughout the whole winter months. Plants treated in this way bloom as freely in the winter as spring-rooted plants do in summer.

The plants in 6-inch pots which supplied these cuttings in July will be benefited by being cut-in or pinched again in August. Another batch of cuttings should be put in then, but instead of placing them in thumb-pots this time they should at once be put into 3-inch pots. In this size they should remain through the winter until March, or whatever time it is convenient to shift them into larger pots. As soon as the cuttings are taken off in August the plants from which they have been taken should be shifted out of the 6-inch into 8-inch or 9-inch pots. With this addition to their root room they again start vigorously into fresh growth and flower freely all winter. In spring the July-struck cuttings should be potted out of their 6-inch pots into others two or three sizes larger, when they will continue blooming throughout the summer. Those in the larger-sized pots may be cut down in spring and formed into cuttings. The plants are not of such a useful size when they become large in a 9-inch pot; besides, small, healthy, well-grown plants under a year old always produce finer blooms than plants on the decline. It will thus be understood that to have Pelargoniums in perfection all the year round there should always be one batch of plants following on the heels of another; and it is a great point to have at least one lot of plants always in their prime, and this is easily enough obtained by propagating frequently, as above advised, and never allowing the plants to become stunted in their pots before transferring them to larger pots.

Throughout the whole of their existence potting and watering are the chief of their wants. At no period of their growth do they require to be syringed, sponged, fumigated, or have any of those endless operations performed on them which are so necessary to the well-being of fancy Pelargoniums, herbaceous Calceolarias, Cinerarias, and many other plants which might be named that only bloom for a brief space and are destroyed.

An ordinary Pelargonium cutting will often bloom if allowed before it is well rooted, and I have seen them when potted-on continue to do so for twelve months afterwards without intermission. Certain varieties may be considered to have much to do with the time and duration of their blooming, but this need not be regarded as a matter of great importance. I have no experience of any other but the Chilwell strain, and I have no particular desire to become acquainted with any other, as many of them include all that is required in a Pelargonium: colour, size, form are there. To be brief, I will not go further back than those which were sent out for the first

time last year, although there are many older than that worth mentioning. Scarlet: John Gibbons, very bright and large trusses, single blooms often measure more than 2 inches across; Rev. F. Atkinson is the finest scarlet of last year's introduction; it is superb in every way, and it has a good companion in this season's lot in David Thomson. With us there is little difference between the flowers, but the leaves of the latter are perfectly green, while those of the former are deeply zoned. Pink: Lady Byron, very fine indeed; Lucy Bosworth; Lady Sheffield, best of all this class; Mrs. Rogers, Sybil Holden, scarlet and crimson, with white eye; Mrs. Whiteley, Earl Manvers, Dora Charlton, A. Henderson (very dark crimson), Charles Smith, E. Davies, Sir H. S. Stanhope, scarlets, in the way of Corsair and Vesuvius, but much better; Wordsworth, Havelock, Lord Zetland. Other beautiful varieties: Mrs. Mellish, rose; Mrs. Leacroft, red, fine white eye; Ellen and Mrs. Jacoby, salmon; Frederick William, rosy plum colour, extra fine; Mrs. Lancaster, clear bright pink; Louisa Smith, vivid crimson; John Fellows, cerise; Mary Pearson, rose; Mrs. Mellish and Evelyn Mellish, light rose. Many more good varieties might be named, but these are very select. All those which are fine and free summer bloomers are generally the same in the winter time.—J. MUIR.

### FRUIT APPEARANCES AND PROSPECTS.

DURING the early part of May, with frost every night, the chance of a crop of fruit of any kind looked a very poor one indeed. Matters have considerably improved since then, and we may now fairly expect to retain such fruit as we have. Pears are almost a total failure, and Apples are partially so. Late-flowering kinds are generally supposed to be the least liable to injury from frost, but they have not escaped this season so well as the early-flowering kinds. Irish Peach and Oslin, which were flowering in the middle of April, have a good crop on them; while Margaret, and others which did not flower till a month later when the frost was more severe, have next to no fruit. Some trees of various sorts shaded on the east side by timber trees from the early sun have also a good crop.

Plums on the west walls are abundant, especially Early Favourite, Cooper's Large, Mirabelle, Purple Gage, and Green Gage; those on the east side have only a thin crop. There was abundance of bloom everywhere, which appeared to set, but only a very small portion of fruit swelled off. Standards do not pay for growing here, as, owing to the soil and climate being rather ungenial, they get covered with insects, and there is no chance to wage war against them as there is with trees on a wall. Many of the wall trees, especially Golden Drop Plums, have much bare wood. I am in the habit of nailing-in some young wood every season to take the place of that which is weak or disfigured; it sometimes bears a few Plums the year after laying-in, and always forms quantities of spurs for fruiting in future seasons. Last year, owing, I suppose, to the unfavourable weather, many of these spurs formed only fruit buds—no wood buds at all, and now the frost has taken the fruit the branches are bare. Cooper's Large, or La Delicieuse, is a valuable Plum, it always bears, and is good for all purposes; it is better than Washington in all respects but appearance. Washington with me is a shy bearer—a very handsome fruit, but only second-rate in quality.

My fan-trained Peach trees are similar to a lady's fan when it has had too much wear and shows rather more framework than is desirable, but still there is some fruit on them and no blister. They had a wooden coping over them a foot wide, and were covered every night with frigi domo from the 9th of March to the beginning of June. Another wall with the trees trained cordon fashion has an abundant crop of fruit; this, however, had the benefit of being sheltered from the sharpest frosts in winter, as I did not consider the wood sufficiently ripe to bear much frost. None of the trees covered at night with frigi domo have a blistered leaf on them, and this includes some maiden trees planted in November. Other maiden trees of the same batch, and treated exactly similar, excepting that they had no frigi domo over them, though they had the same sort of coping-boards, are now quite worthless, every one of them being blistered, deformed, and stunted, and some actually dead. To succeed with Peach trees at all I find I must cover them from their infancy whether they have fruit on them or not. Herring nets, tiffany, and such-like slight covering have been tried and found wanting; they will not keep out 8° or 10° of frost on two successive nights if the intervening day happens also to have a low temperature, and on

two or three occasions this spring the mercury did not rise above 35° any time during the day. A covering like a blanket is needed to keep out such weather.

Although I have such abundance of fruit on my cordon trees, and the plan proves much more profitable here than fan-training, I do not mean to train any more this way, as many of the trees are gumming badly, and plainly show they do not like so much restriction. I think the best plan will be one which is more natural than any of the systems in ordinary use—viz., to plant maiden trees upright, and fasten the laterals on each side to form main branches, making a tree something of the shape of a horizontal-trained Pear, excepting that the branches instead of being horizontal should have an incline of 30° or 35°, and the bearing wood instead of being spurred should be laid-in on each side of the main branches.

There is little or no winter pruning necessary to carry out this plan. A novice can see easier what there is to do to a tree than he can with a fan-trained tree (unless that fan-trained tree would keep as perfect as it does on paper, which somehow or other it never does), and when the sap all flows through one main to branches having all the same elevation instead of five or seven mains at different angles, to supply branches varying in elevation from 0° to 90°, there is a greater chance of having a continuous unchecked flow. There is no need to cut maiden trees down, as is usually done if the wood is ripe, and the laterals generally thought useless as good as any to train-in for a permanency. Those not required should be kept pinched-back till midsummer, and then be removed with the knife, but most of them can with advantage be left on and kept pinched-back to shade the stems.

Light-coloured walls are far preferable to those of a dark colour, the changes of temperature being less violent.

Cherries on walls, including Morellos, are a fair crop. There are none on standards and bushes. Currants are a partial crop and will not be fine. Gooseberries, Strawberries, and Raspberries are very abundant.

We have had a long period of dry weather, and although our heavy soil is quite moist enough 6 inches below the surface, the surface itself had become dry and was cracking. I therefore thought it advisable to slightly mulch all fruit trees and some of the vegetables.—WILLIAM TAYLOR.

### AURICULAS.

I SHOULD find it difficult to say how much my old love for Auriculas has been stimulated and refreshed by the pleasant articles which have appeared from time to time in your pages from the pens of the Rev. F. D. Horner and Mr. Douglas, and I daresay I am not alone in my feelings of gratitude to them for their hints and for the amusement they have afforded to our leisure moments. Notes on Auriculas would seem almost out of place from this damp climate. A moist atmosphere is a characteristic of Wales. The rainfall is large; the amount of cloud and driving rain from the neighbouring Atlantic make it appear even larger than the tell-tale pluviometer will gauge. My garden is in a valley surrounded with trees, and the Rhododendrons thrive to such an extent that we are forced to cut them down in places with a ruthless hand to prevent their overgrowing our paths and smothering one another. Everything is indicative of damp, the enemy of the Auricula, yet "where there's a will there's a way;" and even here with care and attention I have had some blooms which have charmed me and my neighbours, while also some peculiarities have occurred which perhaps other growers may have similarly noticed.

All my plants of Alderman Wisbey, Dickson's Duke of Wellington, Campbell's Robert Burns, Summerscale's Catharina, Smith's Ann Smith, and Mrs. Smith, besides other sorts of which I had but a single representative, never bloomed at all; the plants seemed to be perfectly healthy and vigorous, but they never showed symptoms of forming a truss. Of all my sorts which did bloom none was better than Heap's Smiling Beauty. I had three plants, all of which came out perfectly, and I gather from the prize lists at Manchester that other growers found this fine variety to be in form this year. I had a Col. Champneys in grand condition with nine large pips, which everyone at first sight selected as a gem. Vivid, gay, and dashing it certainly was, but place Smiling Beauty alongside, and the effect was as though you brought a gas jet to bear upon a farthing rushlight, so necessary is the golden throat to light up a first-rate Auricula.

My green edges have been very disappointing. One plant

of Ashton's Prince of Wales came out well with a beautifully pure and vivid green edge, but the other plants were crumpled. Franklin's Colonel is a favourite of mine, very pure and very lasting in the bloom. Oliver's Lovely Ann and Trail's General Niel seem fair and easily increased sorts, but Oliver's Lady Ann Wilbraham was too heavy in the body colour.

The grey edges have done better. Lancashire Hero (one of my plants is green-edged), Lightbody's Inkerman, Cunningham's John Waterston, McLean's Unique, Lightbody's Richard Headly, Fletcher's Ne Plus Ultra, and Turner's Ensign, which last was very fine, only the petals were slightly recurved, opening beyond the flat.

Among the whites after Smiling Beauty came Taylor's Glory, Lee's Earl Grosvenor, Gairns' Model, and Clegg's Crucifix, a very bold large flower.

In the self-edged class I like Lord Lorne as much as any. What a flower C. J. Perry would be with only a brighter eye! Topsy, Pizarro, Blackbird, and Mrs. Sturrock came well.

Slugs have proved formidable enemies. They abound in this damp country, and they will march long distances in the night and go direct to the heart of the best sorts. The larva of *Phlogophora meticulosa* (Angleshades Moth) and *Plusia gamma* (Gamma Moth) have robbed me of Smith's *Lycurgus* and Sykes' Complete; and some Tortrix, which I am rearing to determine the species, has been at work. I have not lost my plants, but the larva succeeded in each case in taking sufficient from the heart to destroy the chance of bloom for the year before I discovered its presence.

Would the Rev. F. D. Horner or other successful raiser of seedlings tell me how they manage their seeding? Is the selection of the pollen parent left to chance or insect agency? or is the pollen taken from one to the other by means of a camel's-hair brush, so that by selection of parentage the failings of an Auricula may be corrected in its offspring? I have tried this plan this year; but I fear that my isolation of the mother plant has been incomplete, and that without a bell-glass to each plant the mere fertilisation of the mother bloom with selected pollen may be insufficient.—J. T. D. L.

## IN AND ABOUT THE TORQUAY LANES.—No. 3.

No weather could be more suitable for enjoying these shaded lanes than that which is now about 90° in the shade, and of those lanes none are more shaded or more beautiful than those around Berry Pomeroy Castle, where I was the day before I am writing this.

Beneath the trees there—evidence of a late season—were still in bloom a few Wood Anemones, and poignantly did they recall to memory the day of boyhood of fifty years since, when I first found that flower in the Langford woods of Essex, and had a word-combat as to the origin of its name. We had no dispute as to Anemone being derived from the Greek for the wind, *anemos*, but we could not agree as to the why a flower which seeks for shade and shelter in woods should be called "The Wind Flower." I believe it was because its pappused seeds are borne "over the hills and far away," even by the slightest wind. My companion, an old parson, who cherished both the Anemone and Ranunculus in his vicarage garden, advocated the growth of the dark-coloured varieties, and I read in the century-old book of the Dutch florist I quoted in my last, "the best sorts to gather seeds from are the deep violets, and such as are all red."

This has but slight reference to the Beech woods of Berry Pomeroy, but it was near a noble specimen of those Beeches that I saw the Anemone *memorosa*. That noble Beech is known there as "The Wishing-Tree," and the well-trampled surface around it testifies that very many pilgrims have thrice passed round it to win what they desire. A noble tree it is, some 150 feet high, with a trunk nearly 200 feet in circumference, and branches covering a circle 100 feet in diameter. It is one of very many I have stood beneath, each associated with some bright aspect of our nature, and testifying that "it is a happy world after all." The Baobab in India, sacred to the most influential of Hindoo deities, and only another name for God; the Gospel Oaks of England; the Mother Vines of Italy; the cleft Ash trees through which to pass the diseased and the crippled; and the Yew trees of many graveyards, but one of the finest here has been taken away, that of Waldon Hill Wood.

I sit within the ruins of Pomeroy Castle, and am saddened that it is one of the numerous possessions of the wealthy of our land that is not rendered residential. No places within

those possessions are so worthy of being tenanted as those which have a history. Berry Pomeroy Castle is one of these, and one of the Seymour family with a judgment and taste deserving commemoration commenced erecting a mansion worthy of his dukedom, but his successors unworthily have allowed it to be swept away. The Castle was built by a Pomerai in the reign of the first William, and remained possessed by his descendants for five centuries, and then was forfeited to the Protector Somerset, in the possession of whose descendants it yet remains.

There and around here I have heard words quite new to me, and which may be jotted down in a cluster. *Lippen*, a bee hive; *cockhedge*, a Hawthorn hedge; *cowstop*, the Foxglove; *cuckoe*, the Harebell; *fast*, the subsoil; *hoop*, a bullfinch; *skeer*, to brush over with a scythe; *tang* and *untang*, to tie and untie; and *wood-quist*, a wood pigeon, the cooing of which I heard on my way to the neighbouring fine half-ruin Compton Castle, to which tradition tells there is a subterranean passage. Compton is a castellated mansion, and I call it a half-ruin because its centre has been rendered habitable, and has a farmer for tenant. Its garden, stone-walled and occupying three-fourths of an acre, is stocked with huge old Gooseberry trees; the walls are covered with Apple and Pear trees, all very old yet fruitful, and I regretted that the fruit was too young for identification, and in the borders were rows of Raspberries and Wood Strawberries improved by culture, but still exhibiting their close relationship to the wild specimens which abound on the hedgebanks all around here. The climate so well suits the wild Strawberries that they may be found flowering in almost every month. The Apple trees are so gnarled and look as old as if they were on the walls when the cannons of the Cromwellians played against the mansion.

Returning to Torquay I halted at the Exhibition of the Torbay Horticultural Society in Belgrave Park, on a site commanding a marine view unsurpassable. I must restrict my notes to the Roses at the Show. The prizes were awarded as follows:—

First prize a silver cup (open), for the largest and best collection of cut Roses, not less than seventy-two distinct varieties.—Curtis, Sandford, & Co. Nurserymen only.—Forty-eight distinct varieties.—Cup, Curtis, Sandford, and Co. Amateurs.—Forty-eight distinct varieties, one truss of each.—Cup, Mr. Beachey; 2, Rev. J. P. Tomlinson; 3, Mr. Robson. Twenty-four varieties, single trusses.—1, Mr. Beachey; 2, Rev. J. P. Tomlinson; 3, Mr. Robson. Twelve varieties, three trusses.—1, Mr. Beachey; 2, Rev. J. P. Tomlinson; 3, Mr. Robson. Twelve distinct varieties, single trusses.—1, Mr. Beachey; 2, Mr. W. Froude; 3, Mr. Spencer-Mead. Twelve best new Roses of 1874 and 1875, distinct, single trusses (open).—Curtis, Sandford, & Co. Six blooms of any Rose of 1875 or 1876.—Curtis, Sandford, & Co. Twelve single trusses of any fine Rose.—1, Curtis, Sandford, & Co.; 2, Mr. Beachey. Large bouquet of Roses.—2, Mrs. Hogg. Hand bouquet of Roses.—2, Curtis, Sandford, & Co. Amateurs.—For vase or epergne of Roses, with foliage only.—1, Mrs. Hogg; 2, Mr. Beachey. Ladies only.—Ornamental basket of Roses, with Rose foliage only.—Mrs. Hogg. Stand of yellow Roses, twelve blooms (open).—Mrs. Hogg. Stand of Tea Roses, twelve blooms.—Curtis, Sandford, and Co.

The seventy-two trebles, for which the first prize was awarded to Messrs. Curtis, Sandford, & Co., comprised the following varieties:—

*Hybrid Perpetuals*: Alfred Colomb, Annie Wood, Antoine Ducher, Antoine Mouton, Alexander Dickson, Arthur Oger, Beesie Johnson, Bernard Verlot, Boule de Neige, Camille Bernardin, Capitaine Christy, Centifolia Rosea, Charles Lefebvre, Col. de Rougemont, Comtesse de Chabriland, Countess of Oxford, Docteur Andry, Duc de Rohan, Duke of Wellington, Duke of Edinburgh, Duchess of Edinburgh, Dupuy-Jamain, Edward Morren, Empereur de Maroc, Etienne Levet, Eugene Appert, Exposition de Brie, Francois Michelon, General Jacqueminot, General Von Moltke, Hippolyte Jamain, John Hopper, Jules Margottin, La France, L'Esperance, Lelia, Louisa Wood, Madame Emma Combey, Madame Chas. Wood, Madame Hippolyte Jamain, Madame Lecharme, Madame Marie Finger, Madame Rothschild, Madame Victor Verdier, Mdlle. Eugénie Verdier, Mdlle. Marie Rady, Marie Baumann, Marguerite de St. Amand, Marquise de Castellane, Mary Turner, Mons. Etienne Dupuy, Mons. Noman, Pierre Notting, President Thiers, Prince Camille de Rohan, Princess Beatrice, Princess Louise, Richard Wallace, Rosa Bonheur, Sophie Coquerelle, Star of Waltham, Victor Verdier, Xavier Olibo. *Teas*: Cheshunt Hybrid, Comtesse de Nadaillac, Devoniensis, Gloire de Dijon, Madame Maurin, Marechal Neil, Marie Guillot. *Bourbon*: Souvenir de la Malmaison. *Perpetual Moss*: Souper et Notting.

I was informed that this Show was the largest and most successful the Society has held, and I can testify that no better specimens of some of the varieties of the Rose could be found in England. Cheshunt Hybrid, Francois Michelon, and Marechal Niel were superlative.—G.

## PEACH BLISTER.

Your correspondent Mr. Luckhurst says in your last volume, page 481, that Peach blister is "caused by the exposure of the expanding foliage [of the Peach] to the influence of frost or cold cutting winds," and as a decisive proof of this being

the cause he instances as follows:—Certain leaves exposed to the east wind suffered from blister, whilst other leaves not so exposed did not suffer. Mr. Luckhurst then goes on to say, "It has also been asserted that blister is caused by a fungus (*Ascomyces deformans*). This is undoubtedly a mistake; the fungus forms upon the affected part simply because it is a favourable medium for its development."

As to the decisive proof of the cold cutting winds causing the blister, does Mr. Luckhurst not know that Peach blister often occurs with great virulence inside the most carefully protected orchard houses? Does the cold east wind sweep unchecked through these structures? When Mr. Luckhurst says the fact of *Ascomyces* causing blister is undoubtedly a mistake, one is tempted to ask, Who says it is undoubtedly a mistake? Mr. Berkeley, who has made vegetable pathology a study for fifty years, says of *Ascomyces deformans* ("Outlines," page 376) that it causes one form of blister, and everyone who knows the genus *Ascomyces* and is acquainted with the habits of the different species and how they distort foliage and fruit, will agree with Mr. Berkeley.

No doubt the east wind will shrivel and wither all sorts of leaves and prepare them for the attacks of all sorts of fungi; but this is quite beside the question. A man may expose himself to the east wind and then die of bronchitis, consumption, inflammation of the lungs, or other diseases, but no one but a quack would say that man died of the wind. A child may sit by a drain and speedily die of diphtheria or typhoid fever, but although the drain may have predisposed the child to the attack, he dies of diphtheria or fever, not of drain. The truth of these statements is proved by the fact of diphtheria, fever, and bronchitis infecting healthy subjects who have not been exposed to winds and drains. It is known to be the same with Peach blister and a large number of other fungoid diseases of plants.

Mr. Luckhurst says, "Can anyone who asserts that fungus is the cause of blister give us any facts in support of a theory which strikes me as being mischievous and calculated to mislead?" As I, in common with many other observers, believe one form of Peach blister to be caused by *Ascomyces deformans* (a form quite distinct from that of tender leaves shrivelled by the east wind), I venture to submit the above facts for Mr. Luckhurst's consideration, trusting they may not prove mischievous and calculated to mislead.—W. G. SMITH.

[Blistered Peach leaves with *Ascomyces deformans* were figured by Mr. W. G. Smith on page 31, vol. xxix.]

### HERCULES AT HOME.

"I AM in lovely bloom; do come over and see my Roses, but it must be either early in the morning or late at night. I stage for Maidstone at 4.30 A.M. (Tuesday)." Such was the message I received from Mr. Baker, and busy though I was I could not refuse the invitation, so I went by the last train to Exeter with the intention of helping him to stage for Maidstone. "If you are waking call me early; call me early, Mary dear," was my request to the Abigail at the lodgings; but, alas! I needed not to be called, for the fear of being too late kept me awake all night, and punctually at 4.30 I turned up at Heavitree. There I found Hercules on the look-out for his gardener, and much astonished to find me instead. However, the old man soon appeared, and then we set to work.

But what a sight met my eyes! I cannot better describe it than by saying you looked over a sea of bloom. There were four thousand Rose trees in full bloom, spread over a space which certainly did not exceed a quarter of an acre, and in my opinion was much less. Every good Rose in cultivation with one exception was in full bloom. That one was, strange to say, *La France*, which with me is always one of the earliest to bloom.

Under the shade of gigantic Elms the boxes were placed, and the tubes filled with spring water, and then we began to cut for the cup, which before these lines see the light will be on the Heavitree sideboard. What a treat it was to stage that stand of thirty-six. The difficulty here was not where to find a grand bloom of a variety, but which to take and which to leave of blooms that would grace any stand. We commenced with *Marquise de Castellane*, and I do not hesitate to say that if we had had to stage twenty-four blooms of that variety we could have done it, and yet left numbers of perfect blooms. I can, although I took no list, tell you all about the best Roses at Maidstone: *Xavier Olibo*, *Annie Laxton*, *Centifolia Rosea*, *Marguerite de St. Amand*, *Ferdinand de Lesseps*,

*Duke of Edinburgh* and his Duchess, *Mdlle. Eugénie Verdier*, *Countess of Oxford*, *Marie Baumann*, all in the finest possible form, and many others too; in fact, when the boxes were closed I only saw two blooms which could in any way be considered weak.

It was a treat also to see the wonderful knowledge displayed by Hercules as to the endurance of the various blooms. *Edward Morren* and blooms of the kind were cut more than half expanded, while *Xavier Olibo* and others of those rapid openers were cut quite in the bud. By seven o'clock all was completed, and the boxes carried off to the cellar, there to wait till the night mail conveyed them in the cool to Maidstone. A box of spare blooms was cut at night. I now predict that the cup value £10 will be awarded to R. N. J. Baker, Esq., Heavitree, Exeter.—JOHN B. M. CAMM.

### RHEXIA VIRGINICA.

OUR figure represents a small family of plants said to be indigenous to the vast continent of North America. Though a small family there is something very interesting about them to the lover of choice, hardy, herbaceous plants. *Rhexia*

Fig. 1.—*Rhexia virginica*.

*virginica* was introduced to our gardens as far back as 1759; the plants of this species require care and skill to cultivate them successfully. *Rhexias* are but little known and less cultivated, and are seldom met with. There are only four or five kinds enumerated in some of the best works we have, but they are a race of plants of great beauty and ought not to remain longer in the background.

Their requirements can be met by imitating their native habitats—sandy bogs. If they are accommodated with sandy peat and moisture success may be expected. They make fine plants on the moist rockery, and they will also succeed with care in a cool peat border, but they must be supplied with water when required. It requires time to get them established, and except for increase the plants should not be disturbed. They are increased by division when growth has commenced in spring. I have not seen or heard of their being increased by seed. They are summer-blooming plants of great beauty, and ought to be much more cultivated than they are at the

present. When well grown and caught in condition they would prove telling plants for exhibition purposes in collections of hardy herbaceous plants.—N.

### RICHMOND HORTICULTURAL SOCIETY'S SHOW.

UNDER the auspices of a favourable day—neither too hot nor too cold—the second annual Exhibition of this Society was held in the Old Deer Park on the 29th ult. The Society, which embraces the district of Twickenham, Isleworth, East Sheen, Kew, Ham, and Petersham, is under the immediate patronage of H.R.H. the Duchess of Cambridge, H.R.H. the Duchess of Teck, H.R.H. the Duc d'Aumale, and H.R.H. the Duke of Teck, who is the President of the Society. It has an influential and practical Committee, and indefatigable officers in Lieut.-Col. F. Burdett, Treasurer, and Mr. Albert Chancellor, Hon. Secretary. Although the Society is young it is prosperous, and its Exhibitions may be numbered as of the best in the vicinity of London. The Deer Park is particularly suitable for a horticultural fête, the Beeches and Oaks being sufficiently large and numerous to afford shade to all visitors without interfering with the enjoyment of an agreeable promenade. Under these fine trees the tents were erected—one 140 feet by 50 feet for plants, and others of smaller dimensions for fruit and vegetables, table decorations and Roses, and cottagers' productions. Large as was the space under canvas it was not sufficient to accommodate without undue crowding the many competing collections, and consequently the arrangements were not so favourable for judging and for inspection as they otherwise would have been. It can never fail to add to the interest of a show if the collections in given classes are placed conveniently near to each other, and this, where space is sufficient and taste is exercised, is not antagonistic to artistic arrangement; but when a first-prize group is on one side of a tent, and the second-prize lot on the other, visitors simply become bewildered in fruitless searches for the different exhibits for purposes of comparison, and obstruction of the promenades is the inevitable consequence.

The Show in question was a crowded Show—crowded with excellent productions, and crowded with a select company of appreciative visitors. The centre of the large tent was devoted to specimen plants arranged on baize-covered stages, the sides being devoted to groups of plants arranged for effect on the grass. These groups were semicircular, each occupying about 100 square feet, and were placed at wide intervals apart, the interspaces being occupied by Ferns, Orchids, &c. The tent had thus a rich and pleasing effect. For the collections mentioned prizes of £5, £4, £3, and £2 were offered, and they were awarded to Mr. Kinghorn, Sheen Nursery, Richmond; Messrs. Jackson and Sons, Kingston-on-Thames; Mr. Bowell, gardener to Sir Henry Parker, Richmond; and F. Wigan, Esq., Clare Lawn, East Sheen, in the order named, an extra prize being awarded to Mr. Bates, gardener to W. H. Punchard, Esq., Poulett Lodge, Twickenham. The whole of these collections were composed of a judicious mixture of fine-foliage and flowering plants, their arrangement generally being of a free and informal character. Prizes of this nature cannot fail to give an impetus to the tasteful arrangements of plants, and we were glad to see the competition so good and the collections so meritorious. Mr. Kinghorn's group was edged with *Lycopodium*; and Messrs. Jackson had a charming fringe of *Agrostis nebulosa* raised from seed soon this spring.

**STOVE AND GREENHOUSE PLANTS.**—In the class for nine plants Messrs. Jackson & Sons had the first place with plants as fresh as if shown in May. Noticeable were *Kalosanthes coccinea* superba 4 feet in diameter, *Aphelexes*, and *Dracophyllum gracile* of still larger dimensions, *Allamanda grandiflora* exceedingly bright, a splendid *Erica obbata*, and a fine *Phenocoma*. These were not one-sided plants, but were as perfectly furnished as they were healthy and well bloomed. Mr. Child, gardener to Mrs. Torr, Garbrand Hall, was placed second for a good collection; Mr. Ellis, gardener to J. Galsworthy, Esq., Coombe Leigh, Kingston Hill, being third for plants still better, but not sufficiently distinct to entitle them to a higher position; they were, however, undeniably well grown. For six plants Mr. Atrill, gardener to C. J. Freake, Esq., Bank Grove, Ham, had the first place with an excellent collection of freely trained plants; Mr. Crafter, gardener to the Rev. W. Finch, Woodlands, Kingston Hill, being second for a somewhat irregular collection, yet containing some good specimens.

For nine fine-foliage plants Mr. Legg, gardener to S. Ralli, Esq., Cleveland House, Clapham Park, was first with the same fine plants which won him the premier place at the Royal Horticultural Society's Show at South Kensington. These plants bear the impress of superior culture, being in exuberant health, rich colour, and, for the size of their pots, they are very large. The *Crotons Weismannii*, variegatum, and *Johannis*, and *Allocasia macrorrhiza* variegata (the finest plant, perhaps, ever exhibited), were in magnificent order; and the *Palms Geonoma pumila* and *Stenersonia grandifolia* exceedingly fine. Mr. Child had the second place with highly coloured *Crotons*, a very fine *Pandanus*

*Veitchii*, large *Maranta zebrina*, *Palms*, &c., a most creditable group; Mr. Kinghorn having the third place with *Palms*, *Phormium tenax* variegatum, *Yucca aloifolia* variegata, *Ananassa sativa* variegata, &c. For six fine-foliage plants Mr. Bates, gardener to W. H. Punchard, Esq., was placed first, Mr. Atrill second, and Mr. Crafter third. Mr. Bowell, gardener to Sir H. Parker, and Mr. Morrell, gardener to J. S. Rutter, Esq., Cambridge Park, Twickenham, staged collections worthy of recognition. In this class, in which the competition was great, size counted far more than quality and effect; all, however, cannot have prizes if all stage good collections.

In the classes for *Pelargoniums* Mr. James, gardener to W. F. Watson, Esq., Redles, Isleworth, was a long way ahead with both show and fancy varieties. The plants were 2 to 2½ feet in diameter, not flat, but semi-globular, more effective than cart-wheel specimens, and in such modern varieties as *Sultan*, *Zephyr*, *Pompey*, *Superb*, and *Example*, all superior; his fancy varieties comprising *East Lynne*, *Mirella*, *Madame Sainton*, *Dolby*, *Lucy*, and *The Shah*. Mr. Wells, Selwyn Court Gardens, Richmond, was second with show, and Mr. Morrell with fancy varieties. In the class for zonals Mr. Crafter was first and Mr. Morrell second for healthy and well-bloomed plants; and for tricolors and bicolors Mr. Tipping, 9, Sheendale Villas, Richmond, had the premier prizes for well-coloured medium-sized specimens. *Caladiums* were remarkably fine, Mr. Morrell winning with robust well-coloured plants 3 to 4 feet in diameter; Mr. James being second with plants almost equally fine; and Mr. Peel, gardener to Lady John Chichester, Cambridge House, Twickenham, third, also for good examples of culture. The *Caladiums* were the finest plants that have this year been exhibited, and Mr. Morrell has now secured the first prize with them for fourteen years consecutively. *Begonias* were fairly well exhibited, the awards going to F. Wigan, Esq., Mr. Atrill, and Mr. Wells respectively for highly creditable collections. *Fuchsias* were well represented, the plants being healthy, well flowered, and not too closely trained. Mr. Crafter was placed first, Mr. James second, and Mr. Wagstaffe third. These collections made a very attractive display, and were greatly admired by visitors.

**FERNS.**—These were remarkably good and very numerous. For six plants, exotic, Mr. Smith, gardener to A. Cooper, Esq., Park Road, Twickenham, was first with *Davallia Mooreana* 5 feet in diameter, *Adiantum gracillimum* 2 feet through, very good; *A. farleyense*, *Gymnogramma ochracea*, and *G. peruviana* argyrophylla and *Lomaria gibba*. Mr. Atrill was second, and Mr. Morrell third, both of whom staged excellent collections. In the class for eight plants F. Wigan, Esq., was first with a very fine *Cyathea medullaris*, a *Dicksonia*, two *Alsophilas*, and four *Adiantums*. Had not these plants been good as well as large they would not have overweighed the second-prize group (Messrs. Rollisson's), which contained beautiful *Filix Ferns*, while many considered Mr. Child's third-prize collection quite equal to the others. It contained a *Cyathea* and *Dicksonia*, both very good, and a highly superior specimen of *Lomaria gibba*. James Wigan, Esq., exhibited an admirable collection of *Adiantums*. Hardy Ferns were rather small but very good, Mr. James being placed first, Mr. Crafter second, and Mr. Morrell third. *Athyrium Filix-femina plumosum* in Mr. James's collection was particularly elegant.

**ORCHIDS.**—These were not numerous, but some good if small plants were exhibited. The first place for eight plants was secured by Messrs. Rollisson & Sons, their collection including *Oncidium crispum grandiflorum*, very fine; *Cypripedium Stonei*, *Saccolabium guttatum* and *Schroederi*, *Dendrobium Devonianum*, *Epidendrum vitellinum majus*, and *Odontoglossum Alexandræ*, all good. Messrs. Jackson & Sons were second with larger plants, including *Lælia Brysiana*, with sepals and petals of snowy whiteness; *L. purpurata*, *Saccolabium retusum* and *præmorsum*, and *Aërides Lobbiani* and *odoratum majus*, very large. Mr. Bates, gardener to W. H. Punchard, Esq., had the third place; an extra being awarded to Mr. Child, *Saccolabium guttatum* in his group being exceedingly fine. Messrs. Rollisson exhibited *Cypripedium spectabile* in superior condition, also *C. niveum* and the remarkably spotted *Mormodes pardinum*.

In the miscellaneous collection of plants Messrs. Veitch staged a choice group, also a collection of *Roses* in pots, very dwarf, very good, and greatly admired; Mr. Dean, Ealing, an extensive and attractive collection of succulents and bedding plants; Mr. Chancellor, very superior *Musk*; Messrs. Osborne & Sons, Fulham, a large and effective group of decorative plants; Mr. W. Steel, Richmond, standard *Hollies*, highly ornamental; Mr. Chambers, Westlake Nursery, Isleworth, dwarf flowering *Begonias*, which surrounded with *Isolepis gracilis* had a good effect; and Mr. Goddard, gardener to H. Little, Esq., seedling bedding *Geranium Rosa Little*, very brilliant and floriferous, which has received a first-class certificate at South Kensington. As specimen plants Mr. Bowell exhibited a good plant of *Pelargonium Unique*; and Mr. Linser, gardener to J. Ball, Esq., West Hay, East Sheen, a specimen of the same type—a pyramid 5 feet high, and 6 feet in diameter at the base. Mr. Kinghorn ex-

hibited a new Fern, *Adiantum hirsutum*, highly distinct and elegant.

**DINNER-TABLE DECORATIONS.**—These were not numerous nor very superior. They were placed also on incongruous and rudely-constructed tables. In Class 62, open to all, Miss Kinghorn had the first place with a charmingly arranged table, the fruit being excellent, and the decorations of flowers and Ferns exceedingly chaste; Mr. Brown, Marshgate, Richmond, having the second place with a neatly arranged table of fruit, Ferns, and Grasses. In Class 63, for ladies of the district, Miss E. Mackinnon, Ham Common, was placed first; Mrs. Askew, Ellerker House, Richmond, second; and Mrs. Mackinnon third, with elaborately arranged tables. For single decoration Miss Rose Little, Cambridge Park, Twickenham; Miss J. Warde, 3, South Terrace, Richmond; and Mrs. Hunter, Isleworth, were placed in the order named. Miss Little's decoration—a glassy pool with Water Lilies, and a miniature bank fringed with flowers—was very ornamental. Bouquets were not good, nor "button-holes" superior.

In this tent a basket of hardy flowers exhibited by Lady Parker was highly ornamental, and it is to be regretted that there was not a better response for the prizes offered by Lady Parker for flowers of this nature; the example sent was very charming. Hanging baskets were also exhibited in the same tent, but some of them were "made-up affairs," and none superior. The prizes went to Mr. Atrill, Mr. Wells, and Mr. Morrell.

**ROSES.**—Of these many boxes were exhibited, Messrs. Paul and Son, Cheshunt, securing the chief prizes for thirty-six and twenty-four blooms in the open class; Messrs. Dobson & Sons being second. Madame Lacharme in Messrs. Pauls' stand was in excellent form. Mr. Laing exhibited good boxes, not for competition. In the amateurs' classes for twenty-four blooms Mr. Moorman, gardener to the Misses Christy, had the first place for an admirable stand, followed by Mr. James, Redlees; and J. S. Virtue, Esq., Otlands Park. Mr. James also secured the special prizes offered by C. Turner White, Esq., and H. G. Bohn, Esq. Other successful exhibitors were J. Wigan, Esq., Rev. W. Finch, Mr. Holford, Mr. Yates, D. Roberts, Esq., R. H. Hunter, Esq., &c. For eighteen bunches of cut flowers Mr. James, Messrs. Dobson & Sons, and Mr. Kinghorn staged good collections, and were awarded the prizes in the order of their names.

**FRUIT.**—There was a good show of fruit, but it was generally not of a high quality. Pines were small but ripe. W. H. Punchard, Esq., was first for three fruits, also for one fruit. Mr. Brown, gardener to H.R.H. the Duc d'Anmale, having a third prize. Grapes were rather extensively exhibited, but with the exception of about three dishes they were brown and not Black Hamburgs. For a single bunch of black Grapes F. Wigan, Esq., was first; Mr. Sallows, gardener to J. J. Flack, Esq., second; and Mr. Bates, gardener to W. H. Punchard, Esq., third; but none of them were superior. For three bunches of black Grapes Mr. Bowell was first with very good Black Hamburgs; Mr. Bates being second with unripe Madresfield Courts; and Mr. James third with small bunches, but the best finished Hamburgs in the Exhibition. For Muscats, Mr. Bates was first with fine, well-filled, and finished bunches; Mr. Fry, gardener to Col. Beresford, being second; and F. Wigan, Esq., third. For a collection of six dishes, Mr. Cornhill, gardener to J. S. Virtue, Esq., was first with a Pine, Grapes, Apples, Peaches, Nectarines, and Strawberries, all good; Mr. Kent, gardener to C. W. Curtis, Esq., Coombe End, Kingston, being second. For Melons (green-flesh), Mr. Pithers, Munster House, Fulham, was first with an excellent and handsome fruit of A. F. Barron, the best Melon in the Exhibition; J. Wigan, Esq., being second with Heckfield Hybrid; and F. Wigan, Esq., third. Scarlet-flesh—first, F. Wigan, Esq., with Cox's Golden Gem; second, Mr. Brown, Orleans House, with Little Heath; and third, Mr. Wagstaffe with a seedling. Mr. Turner, George Street, Richmond, exhibited four fruits of Little Heath weighing 17 lbs. 9 ozs. In Strawberries (two dishes), Mr. James was first with President and Sir J. Paxton; Mr. Croker, gardener to G. Whitby, Esq., second with Sir J. Paxton and Sir C. Napier; and Mr. Fry third with Vicomtesse Hélicart de Thury and Keens' Seedling. For single dishes the prizes went to Mr. Croker, Mr. James, and Mr. Bond. The Strawberries were good and well coloured. For Peaches, Mr. Lake, gardener to Mrs. Boycott, Cambridge Park, Twickenham, was first with Royal George, very fine; Mr. Atrill being second, and Mr. F. Wigan third. For Nectarines, Mr. Lake was first with Violette Hâtive, excellent; Mr. Baker, gardener to W. Budd, Esq., second with Pine Apple; and Mr. Wells third. For Plums, Mr. Baker was first with Kirke's; and Miss Headley second with Transparent Gage. Cucumbers were of fair quality, Mr. Beadle, gardener to E. A. Woodroffe, Esq., winning with White Spine, Mr. Morrell being second with Tender and True, and Mr. Wells third with Monro's Duke of Edinburgh.

**VEGETABLES.**—These were not of high quality. For a collection of ten kinds Mr. Fry, Sheen House, was first; Mr. Bond

second, his collection including good Celery; and Mr. Atrill third. Messrs. James Carter & Co. offered a silver cup value five guineas for eighteen dishes, for which there was very good competition; Mr. Bond, gardener to Mrs. Beckford, Oxford House, Ham, winning, his collection including Mushrooms and Celery, otherwise it was no better, if as good, as some of the other collections.

Potatoes were generally small, Cabbages and Cauliflowers large, Peas scarce, and Turnips and Carrots anything but good. Some of the vegetables staged by the cottagers were fully as good as those exhibited by gardeners. For cottagers many special prizes were given, and a good display of garden products were staged. Altogether the Exhibition must be pronounced a very successful one, and visitors were exceedingly numerous.

## ROYAL HORTICULTURAL SOCIETY.

JULY 5TH.

**FRUIT COMMITTEE.**—Henry Webb, Esq., in the chair. A very fine dish of Tomatoes, called Jackson's Tomato, was sent by Mr. R. Gilbert of The Gardens, Burghley. They were large, almost quite smooth without furrows, and of a fine deep red. It received a cultural commendation. Mr. Wright, gardener, the Manor House, Lower Stoughton, sent a dish of a seedling Pea which very much resembled Dickson's Favourite. As the Committee decline to give an opinion upon Peas except in a state of growth these were passed. Colonel Trevor Clark sent fruit of the Doyenné d'Été Pear perfectly ripe. Mr. Charles Turner of Slough sent a fruit of the White Turkey Cucumber, an old variety now almost out of cultivation in this country, but well known as one of the best in flavour, and with a fine aroma. Philip Crowley, Esq., of Waddon House, Croydon, sent a fine specimen of Shaddock, to which a cultural commendation was awarded. Mr. Gilbert, The Gardens, Burghley, sent several seedling Melons. One, called The First Lord, was raised from the African Melon of Sir S. Baker crossed with Victory of Bath, but it was not considered to possess any merit. The second was a red-fleshed variety, which was also inferior in flavour. The third, Hughes' Golden Nugget, was better than the preceding, but still inferior. The true African was very deficient of flavour. Hero of Bath, a red-fleshed variety, was the best of the collection. Prince's Favourite, another red-flesh, was also inferior. Mr. Oxford, The Hall, Kenilworth, sent a Melon raised by crossing Hero of Bath with Horticultural Prize, but it was inferior in flavour.

A seedling Strawberry called Pioneer was sent by Thomas Laxton, Esq., of Stamford—a handsome cone-shaped Strawberry with a firm flesh, a briskly flavoured fruit with a decided Haut-bois aroma. The skin is dark red, and the seeds are small and prominent. It was awarded a first-class certificate.

A collection of thirty-seven varieties of Strawberries came from the garden at Chiswick. Mr. Batters, gardener to Mrs. Willis Fleming, sent a dish each of Winter Greening and Norfolk Beefing Apples.

**FLORAL COMMITTEE.**—R. B. Postans, Esq., in the chair. A pair of very fine plants of *Spiraea palmata* were exhibited by Mr. Strahan, gardener to P. Crowley, Esq., Waddon House, Croydon. These plants were 5 feet high and through, and each contained thirty heads of beautiful pink flowers, and the foliage was perfect, overhanging the sides of the pots. A cultural certificate was worthily awarded for these fine specimens.

R. B. Foster, Esq., Clewer Manor, Windsor, exhibited seven varieties of show Pelargoniums, and first-class certificates were awarded to Lord of the Isles, a bold highly-coloured flower with large truss and fine foliage, a splendid variety; to Sappho, a dwarf variety of close habit, the lower petals being salmon pink, the upper petals violet cerise, with very dark blotch and white centre, very attractive; and to Toby, a flower of good substance, smooth, and of the most intensely crimson scarlet to be found in Pelargoniums.

A botanical certificate was awarded to Mr. Green, Botanical Nursery, Holmesdale Road, Reigate, for *Eryngium pumilum*, a hardy Thistle-like plant with violet-tinted bracts and spiny florets—an interesting plant.

A first-class certificate was awarded to Thomas Laxton, Esq., Stamford, for double white Pelargonium Mrs. Trevor Clarke. This is not a dirty pink semi-double variety, but is really double and really white. It appears to be a free bloomer, and the trusses are large; the leaves possess great substance and are faintly zoned. This plant is thoroughly distinct, appears to possess intrinsic merit, and is an important acquisition to double Pelargoniums: it can hardly fail to become very popular.

A cultural commendation was awarded to Mr. R. Veitch, Exeter, for a pan of the brilliant-berried plant, *Nertera depressa*, a remarkably fine specimen; the small coral-like berries being packed tier upon tier. This charming alpine plant is worthy of extended cultivation. It is very nearly or quite hardy.

Messrs. Veitch & Sons, Chelsea, exhibited Ferns *Osmunda palustris* and *Nipholobolus lingua cristata*, a very fine *Gloxinia*,

a new *Lælia*, and *Ismene amancaes* var. *integra* with yellow *Narcissus* or rather enlarged *Pancratium*-like flowers, the prevailing colour being bright yellow. It is a very gay plant requiring greenhouse treatment.

Mr. T. Laxton exhibited several new *Roses*; and Mr. Turner exhibited a close dark crimson *Rose*. These varieties require further time to prove their character.

## WESTMINSTER AQUARIUM ROSE SHOW.

JULY 5TH AND 6TH.

FORTUNATE in time of fixture must be written of this Show, for it was timed when *Roses* generally were in fullest beauty. The collections were very superior, many, perhaps the majority, of the blooms being in the perfection of splendour. The competition was also good, and the Show was large as well as excellent, notwithstanding that several exhibitors who had entered failed to fulfil their engagements, a practice which unfortunately would appear to be growing into a system. We cannot do more than record the winners in several of the classes, the varieties being the same as those reported as successful at other shows held earlier in the week, only here they were, as a whole, finer than any which have been previously submitted to the public during the present season, not even excepting the admirable display that was staged at Oxford. The collections were arranged round the sides of the large hall, the table decorations being in the eastern vestibule.

In Class 1, for seventy-two *Roses* distinct (nurserymen), five competitors, Mr. Cant, Colchester; Messrs. Cranston & Mayos, Hereford; Messrs. Paul & Son, Cheshunt; and Mr. Keynes, Salisbury, were placed in the order named with really grand collections; Messrs. Cranston's being the smallest blooms, and Messrs. Pauls' the largest.

In Class 2, for forty-eight trebles, six collections, Messrs. Paul and Son being first, Mr. Keynes second with rather small but beautifully fresh blooms; Mr. Turner, Slough, third, and Mr. Cant fourth. This class was most difficult to judge. Mr. Keynes's were much the smallest and Messrs. Pauls' the largest blooms.

In the class for twenty-four trebles Mr. Turner was first with a grand and most perfect collection, Messrs. Paul & Son, Cheshunt, being second, Mr. Keynes third, and Mr. Cant fourth; and in Class 4, for twenty-four single trusses, five competitors, Mr. Turner was first, Mr. Cant second, Mr. Keynes third, and Messrs. Cranston & Mayos fourth, all staging in admirable form.

In the amateurs' class for forty-eight single trusses Mr. Baker, Heavitree, was first with a formidable collection of undoubted merit; Mr. Nicholl, gardener to T. H. Powell, Esq., Drinkstone Park, Bury St. Edmunds, being second, and Mr. Hollingworth, Maidstone, third.

In Class 10, for twelve Tea-scented or *Noisette* *Roses* (nurserymen), four competed, the awards going in the following order to Messrs. J. Mitchell & Sons, Pittdown Nurseries, Uckfield; Messrs. Paul & Son, Cheshunt; and Mr. J. Keynes, Salisbury. The blooms were larger, but not equal in quality and freshness to those in the following class. For twelve Teas (amateurs), seven competitors, the Rev. J. B. M. Camm, Monkton Wyld, Charnmouth, being first with a splendid stand containing Marie Van Houtte in a style we have never seen equalled; Madame Bravy, Souvenir d'Elise, Triomphe de Rennes, Devoniensis, Catherine Mermet, Céline Forestier, Souvenir d'un Ami, Comtesse de Nadailac, Moiré, Caroline Kuster, and Souvenir de Paul Neron. T. Jowitt, Esq., The Old Weir, Hereford, was second with blooms of almost equal excellence, and J. Hollingworth, Esq., Turkey Mills, Maidstone, third.

For twelve *Roses*, single blooms (open), five competed. Mr. Cant was placed first for a marvellously fine collection; Mr. G. Cooling, Bath, being second; and Mr. R. N. G. Baker, Heavitree, Devon, third.

In the class for twenty-four *Roses* in 8-inch pots (open), Messrs. Paul & Son were first, and Mr. Turner second, for dwarf plants, having from five to ten blooms on each.

For twelve trusses of Alfred Colomb Messrs. Paul & Son were placed first, they being the only exhibitors. For twelve trusses of Duke of Edinburgh Mr. Cant was first with immense blooms; and Messrs. Paul & Son, Cheshunt, second. For twelve trusses of Baroness de Rothschild ten fine collections were staged. Mr. R. N. G. Baker being first with really magnificent blooms; J. Sargent, Esq., Reigate, being second. For twelve trusses of La France there were five competitors, Mr. Burley, The Nurseries, Brentwood, winning with perfectly formed blooms; Messrs. Paul & Son, Cheshunt, having the second place. For twelve trusses of Maréchal Niel, Mr. Cant was first with rather poor blooms. For twelve trusses of Marie Baumann Mr. Turner was first, and Messrs. Paul & Son second, for splendid collections. For twelve trusses of Devoniensis Mr. Cant was the only exhibitor, staging blooms 4 to 5 inches in diameter, and securing the first prize.

In the amateurs' class for twenty-four single trusses the com-

petition was great, and the quality of the collections very good. The first prize was awarded to Mr. Sargent, Reigate; second to Mr. T. Gravely, Cowfield, Sussex; third Mr. Gould, Mortimer, Berks; and fourth Mr. Camm.

In the class for twelve single trusses, nine collections, Mr. Benstead, Rockton, Maidstone, being first with a splendid box; the Rev. A. Cheales, Brookham Vicarage, Reigate, second (admirable); Mr. Ridout, gardener to W. L. Brown, Esq., Reigate, third; and J. H. Pemberton, Esq., and O. O. Hanbury, Esq., equal fourth. All very good.

In the class for twelve *Roses* of 1874, 1875, or 1876 (open), Mr. Turner was first with Villaret de Joyeuse, Miss Hassard, Sir G. Wolseley, Antoine Mouton, Royal Standard, Oxonian, Perle des Jardins, William Gayter, Mrs. Baker, Countess Serenyi, J. S. Mill, and Rev. J. B. M. Camm. Messrs. Paul & Son were second, Duke of Connaught and Duchess of Edinburgh being particularly fine. Mr. Keynes third, and Mr. Cant fourth. In Class 9, for six trusses of any *Rose* of 1874, 1875, or 1876, seven competitors. First prize Mr. Cant for Prince Arthur, a *Rose* of the type of Général Jacqueminot, having great smoothness of petal, extraordinary rich in colour, and sweet—a fine variety. Mr. Turner was second, and submitted in one box Royal Standard, Miss Hassard, J. S. Mill, and Rev. J. B. M. Camm, four *Roses* which should be added to all lists not containing them. Messrs. Paul & Son, Cheshunt, being third for Emily Laxton, perfect blooms and beautiful. For a "vase" of *Roses*, first Mr. Hooper, Bath; three others being disqualified for exhibiting in glasses.

In the plant classes there was scarcely any competition. Fairly good *Fuchsias* were staged, and the prizes were awarded to Mr. Wiston, gardener to R. D. Martineau, Esq., Clapham Park; Mr. Lambert, gardener to H. W. Segelcke, Esq., Herne Hill, Dulwich; and Mr. Watson, gardener to H. Bryant, Esq., Glencairn, Surbiton, in the order named. In the class for twelve *Liliums* (open) Mr. Turner, Slough, was the only exhibitor, staging *L. auratum* with magnificent blooms, *L. pardalinum*, *L. Brownii*, and *L. Humboldtii*, and secured the first prize.

Mr. Hooper, Bath, had a second prize for twelve *Carnations*; he also exhibited *Pansies*.

A first-class certificate was awarded to Mr. R. Dean, Ranelagh Road, Ealing, for double Stock "Mauve Queen," a splendid variety, which should be largely grown. Mr. Osman, Metropolitan District Schools, Sutton, was highly commended for Seville Longpod Beans.

DINNER-TABLE DECORATIONS.—For a table laid for fourteen persons, and arranged so as to show the best means of utilising fruit and flowers in its adornment, prizes of £25, £20, £15, and £10 were offered and were awarded to Mr. C. Burley, The Nursery, Brentwood; Mr. J. Cypher, The Nursery, Queen's Road, Cheltenham; Mr. Harris, Clarendon Park, Salisbury; and Mr. Soder, gardener to O. O. Hanbury, Esq., Weald Hall, in the order named. Highly commended, Messrs. Dick Radcliffe & Co. These decorations will be more fully alluded to on a future occasion.

## BROCKHAM ROSE SHOW.

JULY 1ST.

BROCKHAM is a Surrey village on the banks of the Mole, and gives its name to a kind of peripatetic *Rose* Association, holding meetings by invitation in the grounds of various members of the Association at Brockham, Holmwood, and Mickleham alternately. The Society this year pitched their tent at North Holmwood, where they were most hospitably received by the Ladies Mary and Ann Legge. The principal prizetakers were as follows:—

Class 1.—Champion prize, given by Sir Trevor Lawrence, Bart., M.P. Best box of twelve *Roses* in the Show. Prize, an ornamental object value £2, B. Pawle, Esq. Class 2.—Any kind. Group 1, twenty-four varieties; one bloom or truss of each. Three prizes.—1, Rev. A. Cheales; 2, Mrs. Mortimer; 3, F. Wollaston. Group 2, twelve varieties; one bloom or truss of each. Two prizes.—1, J. O. Pawle, Esq.; 2, E. Horne, Esq. Group 3, six varieties; one bloom or truss of each. Class 3.—All of the same variety. Group 1, twelve *Roses*; one bloom or truss of each. Two prizes.—1, Mrs. Mortimer; 2, Capt. Lang. Class 4.—Triplets of any kind. Group 1, eight varieties; three blooms or trusses of each. Two prizes.—1, Rev. A. Cheales; 2, Mrs. Mortimer. Group 2, four varieties; three blooms or trusses of each. Two prizes.—1, E. Horne, Esq.; 2, Capt. Lang. Class 5.—Teas and *Noisettes*. Group 1, twelve varieties; one bloom or truss of each. Two prizes.—1, Rev. A. Cheales; 2, J. D. Pawle, Esq. Class 8.—Bouquets and devices. 1. One device for table decoration, consisting of *Roses* combined with Ferns or other foliage. Two prizes.—1, Mrs. Chaldecott; 2, Mrs. T. B. Nichols. 2. One device for table decoration of any flowers combined with any foliage. Two prizes.—1, Miss Chaldecott; 2, Mrs. Benecke. 3. One hand bouquet of *Roses* combined with Ferns or other foliage. Two prizes.—1, Miss S. Cheales; 2, Miss Wilson. 4. Button hole bouquet; one *Rose* or *Rosebud* combined with

foliage or other flowers, in groups of not less than three. Three prizes.—1, Mrs. T. B. Nichols; 2, Miss Wilson; 3, Miss A. Benecke.

In this Association and the sister one at Reigate a practice prevails of giving prizes for the best Rose in the Show. This creates considerable interest, and has an educating tendency. Camille de Rohan has several times obtained this honour, also Annie Wood and Marie Baumann. On this occasion Louis Van Houtte was distinguished. Amongst Teas Madame Bravy has come oftenest to the front, and next Maréchal Niel, Gloire de Dijon, and Madame Margottin. This year the winner was Souvenir d'un Ami.

Judges.—W. W. Saunders, Esq., F.R.S.; Rev. A. B. Alexander, and Mr. George Paul.

### ROSES AT WISBECH SHOW.

THE third annual Exhibition of Roses, &c., was held in Colville House grounds (lent by Mr. John Baker) on Thursday last. The grounds were in excellent condition. Like other early Rose exhibitions the blooms at Wisbech showed very plainly the effects of the May frosts. As a rule the flowers were not up to the mark in colour or quality.

Reynolds Hole was well exhibited in several stands. Madame Lacharme, Général Jacqueminot, Maréchal Niel, François Michelin, Marguerite de St. Amand, Baron Adolphe de Rothschild, and Dupuy-Jamain, were the best blooms in the winning stands.

Mr. W. Farren of Cambridge was the most successful exhibitor, securing the three silver cups in the open classes. The amateurs' classes were well contested; but the blooms were wanting in quality and size. A basket of twelve blooms of Madame Lacharme exhibited by Mr. Prince of Oxford were simply superb.

Bouquets were well shown and in good taste, also table decorations were very fair; only it is a pity the exhibitors will crowd so many flowers in. However choice the flowers may be, the stands look so much better with few flowers arranged with taste. Appended is a list of the awards:—

Open classes.—Forty-eight varieties of Roses, one truss of each distinct kind.—1, silver cup value £10, Mr. W. Farren, Cambridge; 2, Mr. J. House, Peterborough; 3, Mr. G. Prince, Oxford. Twenty-four varieties of Roses, one truss of each distinct kind.—1, silver cup value £5, Mr. W. Farren; 2, Col. Read, Elm; 3, Mr. J. L. Curtis, Chatteris. Twelve varieties of Roses, three blooms of each, distinct.—1, silver cup, Mr. L. Farren, Cambridge; 2, Mr. G. W. Piper, Uckfield; 3, Miss Penrice, Norwich. Twelve Roses of any variety.—1, Mr. G. Prince; 2, Mr. W. Farren; 3, Mr. J. L. Curtis. Best specimen bloom of any Rose.—1, Mr. E. Bagge, Islington Hall, Lynn; 2, Mr. J. L. Curtis; 3, Miss Penrice.

Amateurs (including nurserymen within a circuit of ten miles of Wisbech).—Twenty-four varieties of Roses, one truss of each, distinct.—1, Mr. J. S. Curtis; 2, Hon. and Rev. F. J. O. Spencer, Sutton; 3, A. H. Ward, Esq., Elm. Twelve varieties of Roses, one truss of each distinct kind.—1, Mr. J. L. Curtis; 2, Hon. and Rev. F. J. O. Spencer; 3, Mr. J. Burton, Peterborough.—H.

### A PLEA FOR FOXGLOVE CULTURE.

AMONGST the many fine biennials that bloom at the present time, there are possibly none to surpass the Foxglove for its noble appearance. Planted in groups in the shrubbery, among ruins, on extensive rockwork, surrounded by trees, or near the flowing spring or the standing pool, it always gives a charm to them, and grows equally well in sunshine or in shade, in moisture or in drought; whilst its hardiness, long-flowering period, and its various colours ought to commend it to all lovers of hardy flowering plants.

It is a native plant and found growing wild in abundance in some places. Fine as these are they are not to be compared with some of the beautiful varieties in cultivation, especially Ivery's varieties, some of these being so beautifully spotted as to compare with the choicest Gloxinias, the colours varying from the purest white to purple, with several intermediate shades of rose, rose-pink, &c.

It is one of the easiest of plants to cultivate, being increased by seed, which should be sown at once to insure good plants for next year. Seed should be sown in the open ground and covered slightly, the seedlings to be afterwards transplanted where they are to remain for flowering.—J. B. L.

### NOTES AND GLEANINGS.

WE are requested to call attention to an error in the schedule of the Royal Horticultural Society at page 19, where it is stated among Messrs. Sutton's prizes that in the collection of Cucumbers and Melons there is to be a single specimen of

the former and a brace of the latter. It ought to read—a brace of the former and a single specimen of the latter.

— WE have to remind our readers that Messrs. VEITCH AND SONS' FRUIT PRIZES will be awarded at the great Exhibition of the Royal Horticultural Society, which is to be held on the 19th. No doubt these will form a great attraction, as they have always been one of the leading features of the July shows. The vegetable prizes offered by Messrs. James Carter and Co. will be competed for at the same exhibition.

— SOME important EXHIBITIONS are pending. The Alexandra Palace Rose Show on the 7th may be expected to be a great success, seeing that it is timed when Roses generally are at their best. Sandown Park, a new Show, falls on the same day. Nottingham on the 6th (this day), is always a great show. Ipswich, Frome, and Newark Shows are held on the same day, and Reigate (Roses) on the 8th. Only a continuance of "flower-show weather" is necessary to render these events as successful and enjoyable as their promoters can desire.

— WE have been favoured by having a copy sent to us of a reprint of JOHN GERARD'S "CATALOGUE OF PLANTS," cultivated in his garden in Holborn in the sixteenth century. The reprint is "privately printed," and beautiful in the typography and paper. A life of Gerard by the Editor, Mr. B. D. Jackson, is prefixed, which includes, with some additions, the life of Gerard which we took great pains to gather together and publish in this Journal in vol. xxviii., page 145. Our biography is accompanied by a portrait of Gerard.

— THE CITY FLOWER SHOW will be held in Finsbury Circus on Tuesday the 11th inst. The prizes will be distributed by H.R.H. the Duchess of Teck at 2 P.M.

— WE recommend to all METEOROLOGISTS Mr. G. J. Symons's volume "On the Distribution of Rain over the British Isles during 1875." It contains a mass of information besides the record of observations made at eighteen hundred stations.

— SEAGULLS.—Having had one of these birds in our garden for about five years, I can, from experience, state that they are most valuable exterminators of those garden pests slugs, &c. I would strongly recommend any of your readers to procure one.—PAX (in *English Mechanic*).

### CRYSTAL PALACE ROSE SHOW.

JUNE 30TH.

ROSE shows have become so popular and Rose-showing has been brought to such a high state of excellence, the shows which have been held during past years have been so superior and have merited such unmixed admiration, that a show, and especially at the Crystal Palace, is invariably looked forward to with great expectations. It was so last year, and the anticipations were more than realised by the result; and it was so this year, but the result was unfortunately of a different character. The Show was a postponed Exhibition, yet a premature one, for many of the greatest growers were unable to stage blooms worthy of themselves and of the varieties which they exhibited. The Exhibition was not so large as last year's grand display, and its average quality was below that of the last gathering in the same place. Need we say that the chilling ungenial spring has set at nought the highest cultural skill and the best of management in producing the Rose in full perfection?

At this tournament Cant was the conqueror, and set up fine yet not faultless boxes. Paul & Son were not in their old (Cheshunt) form. The Slough Roses were not such blooms as the past has produced, and as we are sanguine the future will equal. The Oxford contingent was scarcely a Princely one; and even Salisbury has not been sufficiently salubrious to enable Mr. Keynes to do so well as he has done before.

Let us now look a little more minutely, commencing with the nurserymen's class for seventy-two varieties, single blooms. The winners were placed in the following order.—Mr. Cant, Colchester; Messrs. Paul & Son, Cheshunt; and Messrs. Cranston & Mayos, Hereford; Mr. Prince, Oxford, receiving an extra prize. The Colchester Roses were as a rule massive in petal, pure, glossy, and fine, and the foliage was good. Amongst the light colours Madame Lacharme was very good, Madame Bravy excellent, as also was Souvenir d'Elise. Of high merit also were Devonensis, Duc de Montpensier, Miss Hassard, La France, Mdle. Marie Cointet, Souvenir d'un Ami, Madame Hippolyte Jamain, Madame la Baronne de Rothschild, and La Boule d'Or. Of darker shades the most noticeable were La Ville de Lyon, Mons. Noman, La Duchesse de Morny, Madame Fillion, Hippolyte Jamain, Marguerite de St. Amand, Mdle. Marie Finger, Abel Grand, Nardy Frères, and Princess Beatrice. The best of the dark Roses were Ferdinand de Lesseps, Fisher Holmes, Dupuy-Jamain, very fine; Mdle. Marie Rady, splendid; Prince Camille de Rohan, Baron de Bonstettin, Auguste Nieumann

Thomas Mills, Beauty of Waltham, Reynolds Hole, and Exposition de Brie. In the Cheshunt collection rich colours preponderated. Very fine were Exposition de Brie, Marie Baumann, Etienne Levet, Duke of Connaught, Mrs. G. Paul, Madame Nachury, Xavier Olibo, Senateur Vaisse, and Maurice Bernardin. Of light colours Madame Lacharme, Miss N. Grain, Madame Vidot, Duchess of Edinburgh, La France, and Madame la Baronne de Rothschild were very fine; and of rose colours the best were Madame Alice Dureau, Elie Morel, The Shah, Rev. J. B. M. Camm, Mons. Noman, Edouard Morren, Madame Therese Levet, and Marquise de Castellane. Fine as many of these blooms were, it was plain that they had not opened kindly, and they spoke as clearly as injured Roses could speak—"bad weather." Messrs. Cranston & Mayos had in superior form Madame Vidot, Mdle. Marie Cointet, Madame Lacharme, Centifolia Rosea, and a lovely Homère. The most noticeable in Mr. Prince's collection being the Teas—Madame Opioix, Alba Rosea, Marcellin Rhoda, Jean Ducher, Madame Margot in, and a perfect Madame Lacharme. There were seven entries.

In the class for forty-eight trebles Mr. Cant, Messrs. Paul and Son, and Mr. C. Turner, Slough, were placed as named. Mr. Cant's blooms were all powerful by their size, quality, and excellence. Dupuy-Jamain was here in splendid form, and very fine were Madame Lacharme, Thomas Mills, Prince Arthur, Maréchal Niel, Louis Van Houtte, Etienne Levet, and Madame Willernoz. Messrs. Paul & Son had as their best Annie Laxton, Henri Ledechaux, Miss Ingram, Mons. Noman very fine, Louis Van Houtte, and Rev. J. B. M. Camm; the most noticeable of Mr. Turner's being Lord Napier, Beauty of Waltham, Mons. Bellon, Marquise de Mortemart, and J. S. Mill. Five competed.

In the class for twenty-four trebles there were nine competitors. Mr. Cant was again first with a formidable collection; Mr. Turner being second, his stands containing many remarkably fine flowers; Messrs. Paul & Son having the third place, an extra prize being awarded to Mr. Prince. The varieties being much the same as those above enumerated. For twenty-four singles eight competed, the awards going in the following order to Messrs. Cranston & Mayos, Mr. Turner, and Mr. Cant.

In Class 5, for twelve Tea-scented and Noisette Roses Messrs. Paul & Son, Cheshunt, were first with splendid examples of Souvenir d'un Ami, Perle des Jardins, Cheshunt Hybrid, Jean Ducher, Marie Van Houtte, Devoniensis, Homère, Perle de Lyon, and Rubens. Mr. R. T. Veitch, Exeter, was second; and Messrs. Davison & Co., Hereford, third. Mr. Prince and Mr. Cant staged admirable collections.

We now come to the amateurs' classes. For forty-eight varieties, single trusses, nine competed, the premier prize going to Mr. Rushmore, gardener to Sir C. R. Rowley, Bart., Tending Park, Colchester; Mr. Nicholl, gardener to T. C. Powell, Esq., Drinkstone Park, Bury St. Edmunds, was second; Mr. R. N. G. Baker, Heavitree; and Mr. Davis, Salisbury, being placed equal thirds. In the first-prize collection Julie Touvais was never staged in finer condition. Pitard was also very fine; and good were Elie Morel, Emilie Hausburgh, Baronne de Rothschild, and Dr. Andry, the rest being small. Mr. Powell's were of more level excellence, and but for their being a trifle too much expanded must have had the first place, which many thought they merited. Souvenir d'Elise was splendid, and almost equally fine were Marquise de Mortemart, Eugene Vavin, Edouard Morren, Princess Mary of Cambridge, Dupuy-Jamain, Exposition de Brie, and Maréchal Niel.

In the class for thirty-six varieties, single blooms, seventeen competed. Mr. Baker was first, Mr. Nicholl second, and Mr. Rushmore third; an extra prize going to Mr. J. L. Curtis, Chatteris. Mr. Baker's blooms were rather small, but splendidly fresh, bright, and beautiful, and with perfect foliage. Mons. Noman, Madame C. Crapet, Camille Bernardin, Auguste Rigotard, very fine; Xavier Olibo, Catherine Mermet, Caroline Kuster, Edouard Morren, and Marie Baumann were the most remarkable in this collection. For twenty-four trebles Mr. Baker was again first with a grand collection, the blooms being full, massive and clear, but not large. Marie Baumann, Baronne de Rothschild, Marquise de Castellane, Camille Bernardin, Mdle. Marie Rady, Louise Van Houtte, Marguerite de St. Amand, extra fine; Ferdinand de Lesseps, and Madame Victor Verdier were just as these fine varieties should be. Mr. Davis, Salisbury, was placed second, and Mr. J. Hollingworth, Maidstone, third. In the class for twelve trebles Mr. Baker was again first; Mr. Henry Atkinson, Brentwood, second; Mr. J. Ridout, gardener to S. Brown, Esq., Reigate, third, an extra prize being awarded to Mr. J. E. Cavell, Bardwell Villa, Walton Manor, Oxford. The amateurs' Roses, excepting, perhaps, Mr. Baker's, were much below the standard of the nurserymen's collections.

In the open classes the competitors were not very numerous. For twelve Roses of 1874 and 1875 Messrs. Paul & Son, Cheshunt, were first, with as the best Mons. E. Y. Teas, a most promising Rose of high quality; Marchioness of Exeter, a light Edouard

Morren, and very good; Miss Hassard, somewhat similar to but better than the preceding Rose; Rev. J. B. M. Camm, Sir Garnet Wolsley, Star of Waltham, and Comte Sereniy. Mr. Turner, Slough, was second, his best being Oxonian, massive and fine; Miss Hassard, very superior; Isaac Wilkinson, a very close dark flower; Hippolyte Jamain, and Dean of Windsor, a promising variety. Mr. Keynes, Salisbury, was placed third, his best blooms being Miss Hassard, Wilson Saunders, and Mons. E. Y. Teas. For six trusses of any Rose of 1875 or 1876 Messrs. Paul and Son, Cheshunt, were first with Rev. J. B. M. Camm; Mr. Turner being second with Miss Hassard, and Mr. Cant third with Antoine Mouton, a faded Paul Néron. For twelve blooms of Duke of Edinburgh Messrs. Paul & Son, Cheshunt, Mr. Cant and Mr. Cavell were the successful exhibitors. For twelve of Maréchal Niel Mr. Davison, Whitecross Nursery, Hereford, was first, Mr. Cant second, and Mr. Webb, Calcot, third. Mr. Davison exhibited a small velvet Rose, La Rosière, which was greatly admired by the lady visitors. For twelve blooms any variety, Mr. J. L. Curtis, Chatteris, Cambridgeshire, was first with Marie Baumann; Messrs. Paul & Son were second with Etienne Levet, Mr. Turner being third with Miss Hassard, extra prizes being awarded to Sir C. R. Rowley for Madame Lacharme, and a prize to Mr. Laxton for Annie Laxton. For a collection of yellow Roses Messrs. Paul & Son, Mr. Prince, and Mr. Webb were awarded the prizes. Mr. Corp, Oxford, had an extra prize for a collection of Tea Roses, and Mr. Laing exhibited the old but charming miniature Rose de Meaux.

Full Roses, such as Alfred Colomb, Charles Lefebvre, Duchesse de Caylus, &c., were sparsely exhibited; while flowers of the Dr. Andry, Exposition de Brie, Auguste Rigotard, and Dupuy-Jamain type were staged freely. Mr. Baker's Auguste Rigotard was perhaps the finest Rose in the Exhibition. Mdle. Marie Cointet, which caused such a sensation last year, was seen in several stands, but in none really superior. Madame Lacharme has improved in character, and is more than holding her last year's position. Rev. J. B. Camm is more firmly than ever established as a constant, if rather small, and extremely sweet Rose—a Rose to be had and enjoyed by all. Miss Hassard, Oxonian, Etienne Levet, and Cheshunt Hybrid were in splendid form. Marchioness of Exeter, R. Marnock, and Duke of Connaught were all well exhibited by Messrs. Paul & Son. Amongst the finest and most promising of the newer Roses were Monsieur E. Y. Teas, and Mr. Turner's new dark Rose Mrs. Baker, which received a first-class certificate. Messrs. Paul & Son, The Old Nurseries, Cheshunt, also had certificates for seedling Roses Emily Laxton and Marchioness of Exeter; and Mr. J. Laing, Stanstead Nurseries, Forest Hill, for Fuchsia Laing's Hybrid, a distinct cross between *F. fulgens* and one of the ordinary greenhouse varieties.

The Table Decorations, always a great feature at this Show, occupied the centre of the transept; there were eighteen tables in competition for three sets of prizes. The tables were 12 feet by 6 feet, and were not allowed to be "cut or mutilated." The great fault with many of the tables was their being overdone with decorations. One exhibitor made a mistake in placing very large fronds of *Lastrea Filix-mas* as an edging to the base of his stands; they nearly covered the tablecloth. There was also considerable sameness about the whole of them, the large white Water Lily and Cornflowers being invariably present. In nearly all the classes the competitors who obtained awards stood very near each other; and the Judges, Miss Hassard (now Mrs. Tyrrel), and Mr. Harrison Weir, spared no pains to arrive at a correct decision, their office being by no means an enviable one. In the open class the first prize fell to Mrs. W. Seale, London Road, Sevenoaks. If any fault could be found with this table it was that the centre stand had too much colour from some very large flowers of *Dipladenia Brearleyana* being placed in it. The other flowers were Water Lilies, small yellow *Dendrobium* flowers, and *Rhodanthe*, with *Adiantum farleyense*. The main flowers in the side stands were *Kalosanthes* and Water Lilies. Wild Grasses were mixed with them. Nearly all the stands were of the same pattern, being a slender glass stem rising from the centre of a flat dish, at the top of the stem a smaller dish, and from the centre of this a trumpet-shaped vase. Mrs. Seale had twelve small glasses with button-hole bouquets of small Rosebuds and Forget-me-nots, and two small glass baskets with white Roses. Mr. C. Burley, nurseryman, Brentwood, was second. The base of his stands were fringed with hardy Ferns, *Lastrea* and *Athyrium*. The centre stand was filled with Roses, *Rhodanthe*, and purple Iris. The small glasses had each double Rosebuds. The side pieces were plants of *Cocos Weddelliana* with a base of Roses and purple Iris. Mr. T. Butcher, South Norwood, was third. The vases here were triplets, and the whole was very nicely arranged, but there was too much of it.

The next class was for amateurs, and Mr. Soder, gardener to Osgood Hanbury, Esq., Weald Hall, Brentwood, was first, and this stand was perhaps as well arranged as any in the Show. The centre piece was a fine *Cocos Weddelliana*, the base being filled-in with *Amaryllis*, white Water Lilies, *Anthurium*, fancy

Pelargoniums, Ixias, and pink Geraniums; the tops of the side stands were filled with Cornflowers, Rhodanthe, and Orchids; the base, *Epidendrum vitellinum*, Cape Pelargoniums, Water Lilies and double rose Geraniums. The small glasses had single Rosebuds, and four glass baskets completed the arrangement. These were filled with single pips of Marie Lemoine double Pelargonium, with a base of Maidenhair Ferns. Mrs. Burley, Brentwood, was second. Her centre stand was nicely balanced with Roses, Water Lilies, &c. The sides were Palms, with similar vases to the centre. Small dishes were very neat, filled with Maidenhair Fern and pale blue Delphiniums. The Rosebuds in the small glasses had the leaves cut off and Fern fronds put in instead—a barbarous practice, as a Rose looks best with its own leaves. Mr. F. Lambert, gardener to H. W. Segelske, Esq., Herne Hill, Dulwich, was third. His three centres were Palms (Cocos). He had small glasses and four baskets.

In class C, for ladies only, Mrs. Burley was first, and her arrangement was very neat, except that the base of the centre piece was a little too glaring with three very large red Cactus flowers. These were alternated with *Eucharis*, interspersed amongst them being *Pancratium*, Iris, and *Anthurium*. *Agapanthus umbellatus* was worked into the base of the side stands. Mrs. Seale was second, and we thought that her table was lighter and more elegant than that of the first-prize. The three stands were of equal size; and the flowers, which were Water Lilies, blue Delphiniums, rose and white Rhodanthes with wild Grasses, Ferns, and *Lycopods*, were tastefully arranged. The third prize went to Miss Edith Blair, 22, Mornington Crescent, Regent's Park. This arrangement was certainly the neatest and simplest in the Exhibition, and was well worthy of a higher position. The base of the centre stand was filled with a most delicate-tinted Iris, crimson *Kalosanthes*, and *Stephanotis*; the top being small Begonia flowers, *Stephanotis*, and a pale-flowered *Kalosanthes*, Rhodanthes, and very fine Grasses; the side pieces were two very handsome *Cocos Weddelliana*, and the base simply blue Delphinium and Maidenhair. Four small dishes each contained a Maidenhair Fern edged with leaves of a *Tricolor Pelargonium*.

In the Miscellaneous class Mr. John Laing, Stanstead Park, Forest Hill, sent two of his new Bronze and Gold Zonal Pelargoniums. One of them the best yet raised, named John Jenner Weir, is a most beautiful plant; the leaf is almost circular, with a narrow edge of greenish yellow enclosing a broad band of chocolate red, with yellow centre. Mrs. Horniman is also a fine sort, with circular leaves and medium band of chocolate red. The same exhibitor sent about thirty-six sorts of Delphiniums, amongst them was a very fine seedling. The colour is a rich deep blue with very dark centre. All the shades of blue were represented from the palest blue to deep purple-blue. He had also a dozen flowers of the old striped Rose, York and Lancaster. Mr. Parker of Tooting sent cut flowers of the English Iris (*I. xiphoides*), many of them being strikingly beautiful. The best were Harlequin, Mercurius, Pelius, Prince of Wales, Bell Brunette, Madame Charme, Heroine, Francois Fayel, and Duke of Portland. He had also some cut flowers of herbaceous Pæonies (*P. sinensis*), also herbaceous and other hardy plants for which he is so famous.

Bouquets were very good, but not different to those of former years. For the best wedding bouquet (open), the prizes went to Mrs. L. M. Chater, 40, Denmark Hill, Camberwell, and Mr. Charles Hepburn, Crystal Palace. For the best opera bouquet (open), to Mr. Charles Hepburn and Mrs. L. M. Chater. For button-hole bouquets (open), to Mr. Charles Hepburn and Mr. W. Wood, High Street, Sydenham.

### MAIDSTONE ROSE SHOW.

This Exhibition was held in the Corn Exchange on June 28th under the auspices of the Maidstone Rose Club; and there was not a box of indifferent blooms in the Show. Most of our principal Rose-growers exhibited. These included Messrs. Paul of the Cheshunt Nurseries, Mr. Charles Turner of Slough, Mr. B. Cant of Colchester, and Mitchell of Uckfield. While among amateurs who came from a distance were Mr. R. G. Baker, Heavitree, Devon; Mr. Thomas Jowitt of Hereford; Mr. Quennell of Brentwood, Essex; and Mr. Harrington of Romford, besides several others.

In Class 6, for forty-eight varieties, three trusses of each, Messrs. Paul & Son were a good first, Mr. B. Cant second, and Mr. C. Turner third. In the first-prize lot among those most conspicuous were grand blooms of *Marquise de Castellane*, *Horace Vernet*, *Baronne de Rothschild*, *Madame Lacharme*, very fine; *Duchess of Edinburgh*, *Princess Beatrice*, *Devoniensis*, and *Mons. Noman*; while the other competitors in this class had, besides similar sorts, *La France*, *Marguerite de St. Amand*, and *Capitaine Christy* in excellent condition. In Class 8, for twelve varieties of Tea and Noisettes, Mr. Mitchell of Uckfield took the first prize, a cup value £5, given by Thomas Hollingworth, Esq. Mr. Mitchell had splendid examples of *Maréchal Niel*, *Narcisse*, *Gloire de Dijon*, *Duc de Margottin*, *Madame*

*Margottin*, and *Souvenir de Paul Neron*. In the class for amateurs (open), thirty-six varieties, one truss of each, Mr. J. G. Baker of Heavitree, Devon, with his blooms stood a long way first, he winning the £10 10s. and cup presented by John Hollingworth, Esq.; Mr. Jowitt of Hereford was second, and Mr. Harrington of Romford third; while for twenty-four varieties (open to amateurs only) J. C. Quennell, Esq., of Brentwood, Essex, took the cup presented by Edwin Amies, Esq., and the first prize. He had in high finish *Madame de St. Amand*, *Maréchal Niel*, *Devoniensis*, *Abel Grand*, *Madame Bonnaire*, *La France*, *Dr. Andry*, *Charles Lefebvre*, *Thérèse Levet*, *Victor Verdier*, and others before mentioned. Their brightness was very striking in comparison to the others. Mr. C. Turner exhibited two boxes of his splendid *Rose Miss Hassard*. This is a conspicuous flower of good shape and substance, and ought to have been placed in a better position than on the floor of the room. He likewise exhibited some splendid blooms of *Rev. J. B. Camm* and *Oxonian*. In Class 6 Mr. Turner's three blooms of *Madame Lacharme* were very superior and very much admired. Local exhibitors, both belonging to the Club as well as the Maidstone Horticultural Society, came in rather numerous, and brought some excellent and well-finished blooms. Many were fresh exhibitors, showing that Rose-growing about the neighbourhood is on the increase. This is mainly due to the Honorary Secretaries of both Societies—H. Bensted, Esq., and Herbert Monckton, Esq.—who combine in their efforts to make the Rose Show at Maidstone a success both practically as well as financially; and this year it was no disappointment in either sense, for it was pronounced by competent judges, such as Messrs. Paul and Turner, to be in all ways a grand exhibition for the season. The stands and devices were very well and gracefully arranged. The first-prize stand came from Mrs. J. B. Green, and consisted of a great variety of Roses of all sections, mostly just opening their buds. There were Fern fronds of both silver and gold, Maidenhair, and common Grasses and Woodbine. Miss Kate Lawrence was a good second, and the Rev. H. Biron third, with much the same style of arrangement.

The following is a list of the prizes:—

Class 1.—Any kinds of Roses. Group 1, eighteen varieties, one truss of each.—1 and cup, T. F. B. Atkins, Esq., Halstead; 2, H. Bensted, Esq., Maidstone; 3, H. F. Warde, Esq., Tutsham, West Farleigh. Group 2, twelve varieties.—1, Rev. H. B. Biron, Biddenden; 2, J. Weld, Esq., Marden; 3, R. W. Tootell, Esq., Thurnham. Group 3, six varieties.—1, J. Smythe, Esq., Maidstone; 2, Mrs. J. B. Green, Tovil. Class 2.—Tea-scented and Noisette. Group 1, twelve varieties, one truss of each.—No entries. Group 2, six varieties.—1, J. Weld, Esq.; equal 2, Mrs. J. B. Green and L. A. Killick, Esq., Langley. Class 3.—Any kinds. Group 1, twelve varieties, three trusses of each.—No entries. Group 2, six varieties.—Rev. H. B. Biron. Class 4.—All of same variety, six trusses.—1, R. W. Tootell, Esq.; 2, L. A. Killick, Esq. Class 5.—Device consisting of Roses combined with Ferns or other foliage.—1, Mrs. J. B. Green; 2, Miss K. Lawrence; 3, Rev. H. B. Biron; 4, L. A. Killick, Esq. Button-hole Bouquet.—1, Mrs. J. B. Green; 2, R. W. Tootell, Esq.; 3, Rev. H. B. Biron.

Open to all England. Class 6.—Forty-eight varieties, three trusses each.—1, Paul & Son, Cheshunt; 2, Mr. B. Cant, Colchester; 3, Mr. C. Turner, Slough. Class 7.—Thirty-six varieties, one truss of each. No competition. Class 8.—Twelve varieties, Tea-scented and Noisette, one truss of each.—1, Messrs. Mitchell, Uckfield; 2, Paul & Son; 3, Mr. B. Cant. Amateurs only. Class 9.—Thirty-six varieties, one truss of each.—Cup and 1, R. G. Baker, Esq., Heavitree, Devon; 2, T. Jowitt, Esq., Hereford; 3, W. W. Harrington, Esq., Romford; 4, Mr. P. Bennett, gardener to W. W. Bursell, Esq. Class 10.—Twenty-four varieties, one truss of each.—Cup and 1, J. C. Quennell, Esq., Brentwood, Essex; 2, J. Sargant, Esq., Reigate; 3, Rev. A. Cheales, Brockham; 4, J. Wakeley, Esq., Rainham. Class 11.—Twelve Tea-scented and Noisette, one truss of each.—1, J. Hollingworth, Esq., Maidstone; 2, R. G. Baker, Esq.; 3, T. Jowitt, Esq.

Open to Members of the Maidstone Horticultural Society.—Class 12.—Twenty-four varieties, one truss of each.—1, J. Hollingworth, Esq.; 2, Mr. W. Wilson, Ashford; 3, Mr. J. Wakeley. Class 13.—Twelve varieties.—1, L. A. Killick, Esq.; 2, Misses Jones, Hayle Place; 3, W. Mercer, Esq., Hunton. Class 14.—Twelve varieties, Tea-scented and Noisette, one truss of each.—1, J. Hollingworth, Esq.; 2, Misses Jones.

The cups were presented by Sir J. Lubbock, Sir Sydney Waterlow, Major Ross, John Hollingworth, Esq., and Mr. Edwin Amies; and a silver cup value £5 was given by Thomas Hollingworth, Esq., for the best box of twelve Tea-scented and Noisette Roses in the Show.

### DRACENA GOLDIEANA.

MR. ABBEY in a recent number of the *Journal of Horticulture* has written very fully on the increase of cultivation of *Dracenas*. In that communication he adverted to the extreme

usefulness of these plants—of those species and varieties in ordinary cultivation, shadowing that there were others of recent introduction surpassing in many respects the old kinds in character and beauty of colouring. He had then probably

in view the celebrated English seedlings which startled the horticultural world by their variety and beauty.

Admitting the value of many of these, it nevertheless cannot be questioned that no English-raised *Dracæna*, nor any

Fig. 2.—*DRACÆNA GOLDIEANA*.

*Dracæna* introduced from abroad, is comparable for distinctness of character and striking and remarkable leaf-colouration to *Dracæna Goldieana*. So thoroughly distinct is this plant that it has been regarded by many as belonging to another genus. It is as a *Dracæna*, however, that it has received high

honours in England, and as a *Dracæna* that it received the gold medal for the best new representative of the genus at the late Great Centennial International Exhibition at Brussels. At that great gathering of the world's floral treasures no other new plant attracted more admiration. No mere description

can convey an adequate idea of *D. Goldieana* to those who have not had an opportunity of seeing the plant.

It is not only not like any other known species or variety, but is altogether unlike them. In the recognised type the leaves of *Dracenas* are more or less lanceolate, and are erect or drooping; but of this species the leaves are cordate, 6 or 7 inches long by 5 to 6 inches broad in the widest part, and are nearly horizontal. Hitherto, also, the colouring in the foliage of *Dracenas* has been arranged longitudinally, but in this plant it is transverse. It is difficult to say which of its two colours preponderate, the zebra-like markings of silvery grey occupying as much space as the olive green.

The accompanying figure, drawn on a reduced scale by permission of Mr. Bull from one of his plants, gives a correct representation.

As an exhibition plant in a collection of *Dracenas* this species is very conspicuous, while as a decorative plant it cannot fail to command attention by its stateliness of habit and by the conspicuous yet chaste markings of its glossy marbled foliage.

The history of the plant is remarkable. It was discovered by Mr. Goldie in Africa, and sent by him to the Botanic Gardens at Glasgow. On its being proved there a description of it was written by the Curator, Mr. Bullen; and on this description and in relying on the judgment and character of the Curator, Mr. Bull without seeing the plant purchased it. It is not yet in commerce.

### ROSE STOCKS.

THE experience of Mr. Peach, page 341, as to the comparative merits of Briar and Manetti stocks may be quite what he describes it; but it must not be supposed that the Briar is everywhere an inferior stock, or tender.

I followed a gentleman tenant of mine here (Cheshire S.) who had budded largely on the Briar, and then (ten years ago) purchased his stock of Roses. I have many of them still, and they must be at least thirteen years old. Most of them are in great vigour, and promising to continue so. The difficulty with some is to keep them in reasonable bounds. A *Gloire de Dijon* is now covering a considerable space of wall, and a picture of health and beauty; and another, which has been left uncut (except taking out old wood), is equally large and flourishing. As to the hardness of the Briar, do not Mr. Peach's facts of the winter in Northamptonshire of 1860 prove too much? If "large Oak trees which had stood 'the battle and the breeze' two or three hundred years" were killed by that frost, it must have been a singularly exceptional case.

The Dog Rose grows here naturally very fine; I never saw it anywhere finer. I have many Roses on the Manetti. They neither do as well generally as Roses on the Briar, and I find the stock shoots from the Manetti so like many of the Roses as to be difficult to distinguish.

Attracted by Mr. Prince's (Oxford) catalogue of Roses on the seedling Briar, I last winter obtained and planted some twenty of them. All nearly are now in fine healthy growth, and with a promise of bloom that would not disgrace Roses which had been in position two years. I observe Mr. Peach says the seedling Briar as a stock is not open to the same objection as the "hedgerow or mop-headed" stocks. With what he says about those I quite agree, and as to their unsightliness, except the flowers. Mr. Prince's method of raising stocks promises, I think, a great advance in Rose culture, and I shall not be surprised, with all deference to Mr. Peach, if the seedling Briar does not put his pet Manetti's "nose out."

I observe on reading the *Journal of Horticulture* that a diversity of opinion and experience is not confined to growing Roses, and may teach us to be thankful that we have so much choice, that what will not succeed in one situation and soil will in another. Indeed it would be scarcely possible to find the place where something will not really flourish, and that is the thing when found out to cultivate. Some of our most beautiful plants badly grown are little better than weeds, and so the converse of common things.—V.

### STRAWBERRIES.

LAST year I planted runners of about nine varieties of Strawberries, selected from the "election" lists in your Journal. With one exception the greater proportion of plants of each variety have flowered, and are setting their fruit. The exception is Sir Joseph Paxton, of which not a single plant has

flowered, although in growth and appearance they seem to have done the best. I conclude they have run to leaf. But what makes it the more remarkable that this kind should alone have failed is, that the half of the plants have received rather different treatment to the other half. One row (about fifteen plants) was removed (owing to being in the way of some alterations) in November, and the other row remained where first planted in the beginning of August. I received the runners from a friend, and know that they were taken from fruiting plants.

I shall not layer from these plants, but as the perusal of your Journal has caused me to estimate this variety as one of the very best I shall let my present plants remain another year, and I write to ask whether I should submit them to any special treatment, such as cutting off the leaves. My soil is a light-coloured virgin loam (Bracken and Foxgloves preceded the Strawberries), and the ground was well trenched and manured for planting, but no manure has been applied since. I shall be glad to have the opinions of practical correspondents on this matter.—J. T.

### BURTON-ON-TRENT SHOW.

THIS Show, held on the 28th inst., was the finest the Society ever had; from fifteen to twenty thousand people were on the ground, all of whom seemed to thoroughly appreciate the beautiful plants and fruit that was collected together.

Mr. Cypher of Cheltenham was first for the twelve stove and greenhouse plants, the most noticeable being *Anthurium Scherzerianum*, forty-six spathes, a beautiful plant; *Gleichenia rupestris*, 5 feet through; *Stephanotis floribunda*, very superior; *Croton Weismannii*, 6 feet by 5 feet; *Dracophyllum gracile*, very good; *Allamanda Hendersonii* and *A. grandiflora*, &c. Mr. Pilgrim, Cheltenham, was second; *Phenocoma prolifera*, *Croton pictum*, *Dipladenia Brearleyana*, *Bougainvillea glabra*, *Croton longiflorum*, *Dracophyllum gracile*, &c., being in admirable condition. Mr. Tudgy, Worcester, being third; *Dipladenia amabilis*, *Anthurium Scherzerianum*, with over forty spathes; *Cocos Weddiana*, a *Bougainvillea*, and *Allamanda grandiflora* being the best plants in his collection. The other exhibits do not call for especial mention, being mainly contributed from the neighbouring gentlemen's seats; but certainly without them the Show would have lost most of its interest, as the plants were admirable specimens of culture. The Rangemore collection is always a special feature of this Show—in fact is a show in itself.

Grapes were sadly in want of colour, but very fine in bunch and berry. Peaches and Nectarines were very fine, the winning half-dozen Peaches weighing 4 lbs. The Pines were very good, the winning Queen weighing 5 lbs. The Cherries and Strawberries were not good. Vegetables were not quite so good as in other years, yet many collections deserved much praise.—J.

### GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE anniversary dinner of the Gardeners' Royal Benevolent Institution was held at the Albion Tavern, Aldersgate Street, on the evening of Friday last. The chair was occupied by Dr. Hogg, Secretary of the Royal Horticultural Society, who was supported on the right by Lord Alfred S. Churchill, Rev. C. P. Peach, Mr. Robert Wrench the Treasurer, Mr. Frank Fuller, Mr. Richard Smith, Mr. T. F. Rivers, Mr. J. Bolton, &c.; and on the left by Mr. G. F. Wilson, F.R.S., Dr. Masters, F.R.S., Professor Bentley, Mr. Marnock, Mr. William Paul, Mr. E. J. Beale, Mr. Charles Lee, &c.; and among the rest of the company were Rev. Canon Hole, Mr. T. Moore, Mr. B. S. Williams, Mr. Charles Turner, Mr. Weeks, Mr. Deal, Mr. James Gray, Mr. Weston, Mr. H. J. Adams, Mr. A. C. Wheeler, and a large gathering of horticulturists to the number of a hundred or more.

This was one of the finest—some say the finest—meeting the Institution has ever had. The room, which is far superior for the purpose to that at the London Tavern where the dinners have been held for many years, was splendidly decorated, Mr. B. S. Williams, Messrs. J. & C. Lee, Messrs. Veitch & Sons, and Mr. Charles Turner having contributed most liberally and gratuitously handsome specimen plants of Palms, Cycads, Tree Ferns, *Dracenas*, Caladiums, and other fine-foliaged plants interspersed with other plants in bloom, and which were not lumped together in a mass as formerly, but distributed all over the room wherever they could be introduced with the greatest effect. The table was richly furnished with the ample resources of the establishment, which were greatly helped by several elaborate plateaux and groups of fruit and flowers presented for the occasion by Mr. Buck and Mr. Dickson, the two great florists and bouquetists of Covent Garden. Nothing could exceed in beauty and richness of quality the group sent by Mr. Buck, which graced the head of the table in front of the Chairman; and the general effect of the whole was such as to call forth the admiration of everyone who was present. Even the toastmaster

was prompted to remark in *sotto voce*, "I have been to many dinners, sir, but I have seen nothing like this in the City of London this year."

On rising to propose the health of Her Majesty the Queen the Chairman was received with an outburst of applause which was long, and often repeated. After the loyal toasts, Lord Alfred S. Churchill having in an excellent speech replied for the army, the Rev. C. P. Peach proposed "The President and the Vice-Presidents of the Institution," which was responded to by Mr. G. F. Wilson, F.R.S., one of the Vice-Presidents.

The Chairman then introduced what is called the toast of the evening, "Prosperity to the Gardeners' Royal Benevolent Institution." He said, in proposing this toast I have to introduce to your notice the claims and merits of an Institution which is not one of those whose history has long been associated with that of this ancient city. Its origin is of more recent date, and does not extend beyond the time of living memory. It was on January 17th, 1839, that a few earnest men, of whom few are now alive, met at the Crown and Anchor Tavern in the Strand to inaugurate a Gardeners' Benevolent Society. Mr. Buchanan of Camberwell was in the chair, and they resolved to carry out the object they had in view. On the 29th of the same month a second meeting was held at Wright's Hotel in the Strand, the Duke of Cambridge having become President. The only members of the original Committee now living are Mr. Chandler formerly of Vauxhall, Mr. W. Gregory formerly of Cirencester, Mr. Lane of Berkhamstead, Mr. Marnock, a name honoured in horticulture, and whom we have the pleasure of seeing with us this evening [great cheering], and Mr. Protheroe of Leytonstone; so that out of the twenty-four members of the original Committee there are only five who are now alive.

The progress of the Institution was slow at first. Dissensions crept in, and charges of mismanagement were made against the Secretary, who was replaced in 1843 by Mr. Cutler, who has remained Secretary ever since, and under whose good management coupled with that of the Committees the Institution has arrived at its present state of usefulness.

With your permission I will take a retrospect of the working of the Institution by way of reviewing our progress, to see what condition we were in in 1842 and compare it with the present. It is well that we should do this occasionally, that we may know whether we are advancing or retrograding. In 1842 we started with a balance in hand of £106 9s. 10d., and our income from all sources was £2042, of which £187 12s. was from subscriptions. We had then £400 invested in consols, and that year £200 more was added; and as the report states, "these gratifying prospects induce them to recommend that two pensioners be elected according to the rules of the Institution." Let us now turn to our present balance sheet of 1876. We start this year with a balance in hand of £441 9s. 8d., and our income from all sources is £1634 2s. 3d., of which £693 is from subscriptions. We have £10,750 invested in 3 per cent. consols, a balance at the bankers' and in hand of £430 12s., and seventy-four aged pensioners on our list who are receiving sums of £16 and £12 a-year. Now we have doubtless made great progress since 1842, but has it been as great as it ought to have been? I think not; and my reason for saying so is that when I look at the printed list of subscribers there are numerous names of employers and employed which arise in my mind whom I do not find there, and who ought to be there. It is to the employers that we must chiefly look to aid the Institution on behalf of the gardener, and I trust that some scheme will be devised of reaching them more effectually than we have hitherto done. But there are many gardeners who can contribute also and who do not. I have heard some even rail against the Institution, while others scoffed at it; but we have seen some of those who when in their prosperity were loudest in their attacks upon it come, both they and their widows, to be recipients of its charity, and thereby have coals of fire heaped on their heads. There are few so poor as that they cannot spare a guinea a-year at least for such a purpose.

I shall conclude my appeal to you with an anecdote which happened to myself. A few years ago I sent a letter broadcast over the land soliciting subscriptions to the Gardeners' Royal Benevolent Institution, and I am proud to say the result was far beyond my expectation. Twelve months ago a person called at the office of the *Journal of Horticulture* in Fleet Street, and sending in his name requested to see me. I was very much engaged, as I usually am, and could not see him, but requested that if he had anything important to communicate he could send me a note. He did not send me a note, but called several times afterwards while I was absent, still keeping his secret to himself. One day he called while I was there, and his name was again announced. "Do you know what he wants?" said I to the attendant. "No, sir; he says he wants to see yourself, and he has some money for you." "Then show him up," said I [laughter]. My visitor was a grey-headed venerable old man of gentle nature and somewhat agitated in his manner. After I had given him a chair he began, "Two years ago you wrote me a letter asking me to subscribe to the Gardeners' Benevolent. At that time I was in great trouble, and I was very

sorry I could not send you anything. My wife had been an invalid for years, and she was then at her worst; the doctors had given her up, and they said nothing would do her any good but her native air. She longed to go there, and wished to be buried in the churchyard of her native place. I took her down to Langholm in Scotland; that is where she was born, and after a fortnight she died. It was a great expense and sore trouble to me; but you know, sir, I did my duty to her and fulfilled her last request. Then I thought of your letter and began to save, and now I bring you £10 for the Gardeners' Benevolent." Gentlemen, does not that touch your heart-strings and make them vibrate? If so great an effort can be made by one so humble, what may not you and we all do for the poor gardener if we but try? The Chairman sat down amidst great applause.

The next toast, "the Health of the Chairman," was proposed in a clever and humorous speech by Rev. Canon Hole. "The Treasurer and Trustees" was proposed by Dr. Masters, and responded to by Mr. Robert Wrench the Treasurer. "The Royal Horticultural and Botanical Societies of London" was proposed by Mr. W. Paul, and replied to by Lord Alfred S. Churchill and Professor Bentley. "The Seed and Nursery Trades, and thanks to them for their services to the Institution," was proposed by Mr. Frank Fuller and responded to by Mr. B. S. Williams.

On the health of the Secretary being proposed by the Chairman Mr. Cutler returned thanks, and announced that the subscriptions of the evening amounted to upwards of £500.

The music, which was under the direction of Mr. W. Ganz, assisted by Miss Annie Sinclair, Madame Marie Belya, Mr. Trelawny Cobham, and Mr. Maybrick, was executed in a very masterly style, and elicited repeated rounds of applause.

## OXFORD ROSE SHOW.

Much might be written about Oxford—of the beauty of its architecture, its trees, and its gardens, but our remarks must be limited to the grand display of Roses under the Lindens in the grounds of Trinity College. The Show was a postponed Show, and the only day that could be found for a second fixture was Monday, the 3rd inst. Monday was felt to be an unfavourable day, especially for distant exhibitors, but the time for staging the blooms was prolonged until one o'clock, and this enabled an exhibition to be made—even the finest exhibition that up to its date had this year been held in England. Of course when there was such a race against time the trains must be late, yet by extraordinary efforts all collections were staged in time for judging. The Show was arranged as if by magic, and it was with great reluctance that some exhibitors ceased the work of trimming and touching-up their blooms when judging commenced.

The Show was not only intrinsically good, but it was decidedly novel, and unquestionably one of the most delightfully enjoyable Exhibitions that has been held at any time or place. The collections were not arranged under a plastered roof, not even under a roof of canvas, but under a living roof of Limes. This Lime avenue is remarkable for its regular formation and the density of its arch of green. The trees are growing 5 yards apart in two rows about 20 feet asunder. The trees have been roughly pruned at 20 feet from the ground, and their branches arch over and sweep the grass. Underneath the main branches are bare of foliage, and arch over almost with the regularity of the ribs of a cathedral's nave. The light beneath is subdued, and the most powerful sun could not penetrate the thick canopy of foliage. On the day of the Show the sun was not bright, and the bower, 120 yards long, was fully too dark to show the dark Roses to the best advantage; but it was deliciously cool and roomy, and no exhibition under canvas could have been so completely enjoyable and satisfactory.

In the open class for seventy-two varieties, single blooms, Messrs. Paul & Son, Cheshunt, had the first place, followed by Mr. Prince, Oxford, and Mr. Turner, Slough, in the order named. Messrs. Paul & Son's Roses were very massive. Edouard Morren, Marquise de Castellane, Henry Ledechaux were in fine condition. Duke of Edinburgh, Louis Van Houtte, Mons. Noman, Eugénie Verdier, Nardy Frères, Marquise de Gobat, Ferdinand de Lesseps, La France, Mdle. Marie Rady, Beauty of Waltham, Etienne Levet, Emily Laxton, Annie Laxton were all in the old Cheshunt form, and what that is many know—some too well. Amongst the light flowers Madame Lacharme was very beautiful; there were also good blooms of Marquise de Mortemart and Alba Rosea. Mr. Prince's was a fresh and beautiful collection, the blooms not large but just in their best state. Dr. André and Souvenir de Mons. Boll were very splendid; and Marie Baumann, Madame Lacharme, Charles Lefebvre, Duchess of Edinburgh, Madame Fillion, Camille Bernardin, Felix Genero, Maréchal Niel, Homère, and Triomphe de Luxembourg were all in superior form. It was not size but quality and freshness that found favour with the Judges. Equal in these respects were Mr. Turner's blooms, and they were also larger. This was a splendid collection, in which the following were noticeable—Mrs. Baker, Oxonian, Miss Hassard, Sir G. Wolseley, Royal

Standard, J. S. Mill, Annie Laxton (gem of the stand), Star of Waltham, Horace Vernet, a grand bloom; Louisa Wood, excellent; Louis Van Houtte, Etienne Levet, Abel Grand, Ferdinand de Lesseps, Villaret de Joyeuse, Madame Charles Wood, Mons. Noman, Pitard, Baroness de Rothschild, La Fontaine, Alba Rosea, Edouard Morren, Marquise de Gobat, Madame Vidot, and Maréchal Niel. Mr. Farren, Cambridge, also exhibited; his collection including a seedling, Alice Farren, a soft General Jacqueminot, of beautiful form, smooth petal, and altogether good, and another seedling of the Horace Vernet type but deeper. Messrs. Cranston & Mayos, and Messrs. Davison & Whitten, Hereford, also staged admirable collections in this class.

In the class for forty-eight trebles Mr. Prince was first, Mr. Turner second, and Messrs. Davison & Whitten third. Mr. Prince had some magnificent blooms, such as Etienne Dupuy and Edward Morren, and charming triplets of Gloire de Sante-nay, Madame Opoix, Souvenir d'Elise Vardon, Madame Bravy, Mlle. Marie Cointet, and Jean Ducher. "The Teas pulled him through" was the general remark; but of more uniform excellence was the Slough collection, which was weakened only by Capitaine Christy and Souvenir de la Malmaison, which were too much expanded; Royal Standard, Mlle. Thérèse Levet, Mons. Noman, J. S. Mill, Pitard, Madame Liabaud, very pure; Miss Hassard, splendid; Ed. Morren, Rev. J. B. M. Camm, Louisa Wood, Oxonian, François Michelin, Etienne Levet, Maréchal Niel, Beauty of Waltham, and Marquise de Castellane were as near perfection as these fine Roses can be. In Davison and Whitten's collection Bessie Johnson was quite lovely, as also were Marguerite de St. Amant and Mlle. Marie Finger; Madame Lacharme was also very good, but the blooms were generally small.

For forty-eight varieties (singles) Mr. Turner, Mr. Prince, and Messrs. Paul & Son, Cheshunt, were placed in the order named. In Mr. Turner's boxes Baroness de Rothschild, François Michelin, and Louis Van Houtte were wonderful blooms; and very fine were Etienne Levet, Xavier Olibo, and Miss Hassard, but all were good saving Gloire de Dijon. Mr. Prince's were smaller, but very compact and remarkably fresh, of the same varieties as previously enumerated; Messrs. Pauls' being very large, some even too large, yet many very perfect, especially Etienne Levet, Madame Laurent, Dr. Andry, Annie Laxton, Centifolia Rosea, &c.; the foliage was also very exuberant.

In the class for twenty-four varieties, singles, Mr. Cooling, Bath, had the premier position for a remarkably good collection. For sixteen triplets Mr. Arkwright, Hampton Court, Leominster, had the first place. He had Maréchal Niel in grand form; Catherine Mermet, exceedingly lovely; Madame Lacharme, Fisher Holmes, Charles Lefebvre, and Souvenir d'un Ami, all in admirable condition. Mr. Cooling was placed second, also with very fine blooms.

For twelve blooms of Marie Baumann Mr. Turner, Slough, won with one of the finest collections ever staged; second Mr. Farren, smaller. For twelve Maréchal Niel, first Mr. Arkwright, Leominster, for a magnificent dozen; second Mr. Prince. For twelve Baroness Rothschild, equal first Mr. Prince and Mr. Farren for noble stands. For twelve La France, first Mr. Cavell with wonderful blooms; second Mr. Prince. The exhibits in this class were remarkable for their great excellence.

For Teas Mr. Jowitt, Mr. Prince, and Mr. Cavell were placed as named. The best blooms were Perle de Lyon, Madame C. Kuster, Homère, Belle Lyonnaise, Madame Margottin, Marie Van Houtte, Reine du Portugal, Adrien Christophle, Naricise, Madame Charles, Madame Opoix, Jean Ducher, Souvenir de Paul Neron, Bouquet d'Or, Rubens, La Boule d'Or, Comte de Paris, Madame St. Joseph, and Anna Olivier.

Amateurs.—In the class for forty-eight varieties, single blooms, there was great competition, and many blooms of high character were exhibited. Mr. T. H. Gould, The Vicarage, Mortimer, secured the first prize. The collection included grand examples of François Michelin and Edouard Morren. Amongst lights Alba Rosea, Mons. Van Houtte, America, and Perle de Lyon were all excellent. The second prize went to Mr. J. H. Arkwright with a collection almost equally good, and containing the finest Maréchal Niel we have ever seen exhibited. Mr. Thomas Start, gardener to Rev. C. Evans, Solihull Rectory, near Birmingham, was third, also with a most admirable collection, Madame Lacharme, Belle Lyonnaise, Marie Van Houtte, and Lord Macaulay being in the perfection of loveliness.

For thirty-six varieties, single blooms, Mr. Jowitt, The Old Weir, Hereford, was first with a beautiful collection of perfect blooms, not large, but "in" to the hour. C. Rouillard, Annie Wood, Charles Lefebvre, Le Havre, Mlle. Marie Rady, Mons. Noman, Xavier Olibo, François Michelin, La France were all in the highest possible state of excellence; Mr. J. E. Cavell, Bardwell Villa, Walton Manor, Oxford, being second for a remarkably good collection. Mr. Scott, Warminster, Wilts (Mr. Goodfellow, gardener), having the third place for highly creditable blooms. For twenty-four varieties Rev. C. Evans won with a really admirable collection; Emilie Hausburgh, Madame George Schwartz, and Annie Laxton were highly superior; and

for eighteen varieties Mr. Bradley, Oxford, was first with capital blooms.

In the classes for members of the Society there was spirited competition, and the quality of the blooms was highly complimentary to the several exhibitors. For thirty-six varieties the prizes were secured by Mr. W. J. Emberlin, Mr. J. Bloxham, and Mr. W. Freeman, in the order named; for twenty-four varieties the awards went to Mr. Charles Patey, Mr. Arthur Evans, Mr. Charles Taylor, and Mr. J. P. Bradley; for eighteen varieties Mr. D. Chapman and Mr. Charles Davies won with very good boxes; and for twelve varieties the successful competitors were Mr. J. G. Bartlett, Mr. C. R. Ridley, Mr. John Allin, and Mr. W. Cauldwell.

In the remaining classes excellent blooms were staged, notably those of Mr. Freeman and Mr. Calcutt, which would have done credit to any professional exhibitor.

Bouquets of Roses were numerous, but too formally arranged, and the Judges appeared to have awarded the prizes to those who had packed the blooms together the closest, but *ça çon à son goût*.

Both in quality and extent this must be regarded as one of the most successful exhibitions of the year, and the company was exceedingly numerous and appreciative. The judging was expeditiously done. Mr. Ridley's plan of having the names of the exhibitors printed on large cards, and pasting across each the words "first prize," "second prize," and "third prize," is a system not easy to improve. To Mr. Ridley's (the Hon. Secretary) efforts—his zeal, ability, and industry—the Society owes a large measure of its success. Need it be said that the officials of a Show so well managed were attentive and courteous to all?

### OUR BORDER FLOWERS—MADWORTS.

SOME of them are closely allied to shrubs, and are frequently described as half-shrubby. Generally speaking the perennial species are evergreen. We cannot say of the Madworts as we have to say of many of our old border flowers, that they are neglected; far from that, for in many places they are much cared for, and reward the cultivator with a display of their beautiful flowers. What would our spring gardens be without them? What would our herbaceous borders or our rockeries be without those charming occupants during spring and early summer, and often in the autumn and winter furnishing us with stray blooms?

I know of no hardy plants that are more effective than the Alyssums. To see well-established plants of *Alyssum saxatile* compactum, a sheet of bloom with its intense orange hue, cannot easily be forgotten. Others of this charming group are also effective, but the above, in my estimation, carries off the palm. The variegated form is a useful summer bedding plant. *Alyssum spinosa* is a fine addition to our border flowers; it may be turned to good account for all purposes, but especially so in a choice selection of rock plants. *Alyssum olympicum*, *A. montanum*, and others of the family are very ornamental plants.

They may be raised from seed, but are much better from cuttings, as the seedlings are inconstant. Sometimes they may be increased by division, but I find them answer best from cuttings in the early autumn when they have partly matured their growth; they may be cut across at a joint or taken with a heel pared smooth and inserted in moist sandy soil, with good drainage, either under hand-glasses or in cold frames in a shaded situation. When rooted they are best potted and plunged in sand or ashes till required for planting. They will bear a good deal of rough usage, often lasting for years, but are all the better for being often renewed, as old plants become unsightly, having an untidy appearance.—VERITAS.

### NOTES ON VILLA AND SUBURBAN GARDENING.

THE AMATEURS' VINERY.—Now that late Grapes are approaching the stoning stage they ought to have the fullest attention paid to them, for a little extra care given now has a very marked influence on the crop.

I have lately inspected three or four of these small vineries, and where the crops were fairly good; but the shoots and foliage have been let alone till they have all become matted together. Now, it is difficult to advise in a case of this nature. If the shoots had been disbudded in their earlier stages of growth, and those left to support the crop had been regularly stopped as previously advised, the bunches and berries would have been larger and the foliage more healthy and better developed. If I advised regular training-up of these neglected growths now I should expect shanking to take place and almost a stoppage of growth, and the berries would most likely be of a foxy colour when ripe instead of possessing the blackness and fine bloom

characteristic of a good Grape with fine flavour. I like to regulate the growth of Vines, so that when or just before they commence colouring the shoots may grow and be kept growing all through the colouring process.

In the case of the Vines referred to I would advise that they receive a very gradual thinning of the lateral shoots, and when that is done, say at two or three times, then the points of the leading shoots may be pinched-out. This will stop rapid growth, yet it will secure ample foliage for the perfection of the crop. Vines neglected in this way are subject to mildew through the condensed moisture settling continually on the leaves and berries.

I am an advocate for allowing Vines to become dry once in every twenty-four hours; after that, when they receive moisture, they can absorb it for the purposes of growth instead of its inducing a stagnant atmosphere from which something injurious is sure to arise. Let there be a circulation of air night and day in these small places, and if the house is placed in a hot sunny position water must be thrown on the floor and over the stages of the house three or four times in the day.

Fires may be dispensed with unless the atmosphere outside is dull and very close, when a little fire heat sufficient to put the inside air in circulation will be necessary. While the berries are stoning they seldom swell much, but as soon as that is over the last swelling before that of colouring takes place, and if the Vines are in a healthy state through that swelling the colouring process may be expected to progress satisfactorily.

Outdoor Vines are now in bloom, and as their season is short and the weather uncontrollable there must be no neglect now. Let all the bunches have full exposure to the sun, so as to induce them as much as possible to come into bloom all at once. In the case of an individual bunch it often happens that if one part of the bunch blooms and sets its fruit before the other part that bunch is irregular, many of the berries not swelling into a size worth having, so that there are two crops in different stages, one of which is fit to use and the other is not.

Early thinning is a great advantage, and it should be done well—I mean that the most promising berries must be left, and all of about one size, and they may be expected to do well.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

OUR ground is still dusty dry. Rain has fallen south, north, and west of us, and within little more than a mile, but we have not had enough to lay the dust. Allusion was made in the "Doings" at page 495 to the advantages of deep trenching, and the rainfall on June 15th was stated as 6.5 inches, it should be 0.65 inches, or the 65-100 part of an inch. The crops are coming in far too quickly; spring and autumn-sown Cauliflowers are nearly together, and the first and second sowing of Peas are the same. The new variety, Dr. Hogg, is bearing an abundant crop of its large curved pods. William I. is slightly before Alpha, and has the advantage of it for show, the pods being larger and of a much darker green. Alpha being a wrinkled Marrow is more esteemed in the kitchen. All the pods are gathered as soon as they are ready, as if they are left on till they are too old they exhaust the plant and prevent fresh young pods from filling out. We have not yet watered the Peas, but those who find it necessary to do so should not pour the water down upon the stalks, but should draw shallow drills on each side of the rows about 5 or 6 inches from the plants; these should be filled twice with water, and the ground may be hoed over, mulching it with litter if possible. The new Seville Longpod Bean is bearing an enormous crop of large handsome pods. It is now ready for gathering, and is earlier than the Windsor; it seems to be the best sort for exhibition purposes. As the early crops are cleared off the ground is immediately trenched for other crops. The quarter of early Peas is devoted to Strawberries. They will be planted out this year about the middle of July. A good crop to succeed the exhausted Strawberry plants is Broccoli, and as the beds were well trenched and richly manured about twelve months ago the Broccoli may be let into the hard soil with a crowbar after the ground has been cleared from weeds. We have placed stout long sticks to the Scarlet Runners, as we depend on them to supply us with gatherings until the frost comes, and it is astonishing for how long a period they will continue to bear in rich deep soil when the rows are well supplied with water. It is not absolutely necessary to place sticks to this crop. The farmers who grow for the London market do not stick them; they pinch the leading points out, and the plants naturally form a ridge about 2 feet in height. We are planting out in trenches the main crop of Celery. In dry seasons this crop is frequently injured through becoming too dry. From the time the plants appear above ground until they are ready to dig out of the trenches for use they ought not to suffer from drought in any way. The Celery maggot is doing considerable injury to the leaves. By a little patience the pest may be destroyed by crushing it

between the finger and thumb. A full crop of Savoys should now be planted in good soil. Crops of Coleworts and early Cabbages should be planted on all vacant ground as soon as it is cleared of Potatoes, or indeed any crops. There are but few gardens where the ground can be allowed to lie vacant; it must produce at least two crops in one season if cleared by the end of this month. Broccoli should be planted in different situations, and we advise all who have the opportunity to try a plantation under the shelter of a north wall. Broccoli suffers more from alternate sunshine and frost than if it is exposed to frost and the sun is not allowed to shine upon it.

Carrots sown now come in very useful in October and November. Artichokes are now ready for use, and as soon as the heads are cut the stalks should be cut off as close to the ground as possible. We have also made the last sowing of Dwarf Kidney Beans. As this sowing is intended to last until the frost cuts down the plants, the sowing is made in a sheltered position. Under a wall facing west is very good, as here the crop is sheltered from the east winds and the sun does not act upon the plants very early in the day. The crop should be gathered as soon as it is ready, for the plants are soon exhausted if the pods are allowed to hang too long. The plants will sometimes produce gatherings well into October. It is necessary to water the drills well before sowing.

This is also a good time to make a sowing of Turnips for autumn use. The plants come in with us in September and onwards. A later sowing continues the supply until they run to seed in spring. Small salading must be regularly sown in a shady position. A north wall is best for this.

### PINES.

In ordinary seasons the earliest Queens would be nearly over by this time; so far only two or three fruits have been cut in our house, but the suckers are very strong, and will be potted when the plants are ready to be removed from the bed. It is no use potting them sooner, as the bed will not be ready for them until the succession plants are removed from the bed intended for the suckers. Most likely the suckers will not be potted for a month, and they are not expected to bear fruit until 1878. Fire heat has been dispensed with in all the houses, as the weather is very mild at present. The succession plants are rather backward, but the house is not sufficiently heated, and it has not been possible to hurry them on. We are careful to see that none of the plants suffer for want of water at the roots, as over-dryness is very apt to throw Pine plants prematurely into fruit. There are a few Cayennes and Charlotte Rothschilds throwing up fruit which will ripen in autumn and winter. These plants are aided by a little guano dropped in the water at every alternate watering.

### ORCHARD HOUSE.

Except one tree of Early Rivers Peach, which has the fruit stoned and taking the second swelling, all the other trees have the fruit passing through the stoning period. All the trees are in pots; and they require very large supplies of water at least twice daily. The pots have also been mulched with decayed manure and turfy loam in equal proportions. The material is pressed down upon the surface quite firmly with the fingers. We syringe the trees at 6 A.M. and about 5 P.M. daily. All the Strawberry pots have now been cleared out of the house.

### GREENHOUSE AND CONSERVATORY.

Show Pelargoniums are getting past their best, but they still make a tolerably good show. Zonal Pelargoniums ought now to be at their best, and the many different shades of colour—white, pink, salmon, scarlet, crimson, &c., can be arranged so that a fine effect is produced from this class of plants alone. Primulas, Cinerarias, and Calceolarias require to be kept clean, and the plants suffer if exposed directly to bright sunshine. A house with a north aspect suits them best, but if this is not to be obtained the plants must be shaded when the sun strikes directly upon them. Cyclamens are at rest at present, and the plants have just as much water as keeps the foliage from flagging. Hyacinth and Tulip bulbs are quite ripe, and have been turned out of the pots. These roots are always potted, and they flower tolerably well the second year. About three Hyacinths and six Tulip roots are placed in a 6-inch pot. Tying and training Chrysanthemums. All the specimen plants are now in their flowering pots, and the shoots have been pinched for the last time, at least the late-flowering sorts. Aphis has been very troublesome, and as it is difficult to dip the growths in the usual solution the points have been dusted with snuff. We syringe frequently in hot dry weather.

Specimen hardwooded plants are better for being placed out of doors at this season, but the sun must not be allowed to act upon the sides of the pots, else the roots may be destroyed. A slate or board may be placed against the pots to prevent this. All plants subject to be attacked by red spider or thrips should be freely syringed.

### FLOWER GARDEN.

The Dutch hoe has been kept at work amongst the bedded-out plants, and so far nothing seems as yet to have suffered from the drought except the old yellow shrubby Calceolaria rugosa. This

variety is the most hardy sort we have and flowers very freely. It would be very beneficial to the plants if we could give them all a good watering, and then mulch the surface of the ground with decayed manure. Asters also suffer from the attacks of insect pests. The beds have been well watered and mulched, and if this does not start the plants into healthy growth they will be syringed daily with soot water. This causes the foliage to become of a darker green, and soot is obnoxious to most insects. Pinks are in splendid bloom. The plants never were more healthy or the flowers better laced than they are this season. Each plant has about a dozen well-shaped flowers on it at one time. Carnations and Picotees are also coming freely into flower, and it seems as if there would also be a good show of them. Auriculas are very quiet behind a north wall. The plants are carefully watered, they are kept clear from green fly by brushing it off; there are always a few withered leaves at this season which are picked off, and the weeds are not allowed to remain in the pots.

Herbaceous borders require frequent attention at this season, else the stronger-growing subjects quite destroy the more dwarf and tender species. Each plant ought to have its allotted space, and must not be allowed to grow beyond it. Many persons complain that certain tender alpine plants do not succeed with them. How can they unless they have space to grow? The reason is not always the unsuitable soil and situation, but simply that the weaker plants are smothered with their robust neighbours.—J. DOUGLAS.

### TRADE CATALOGUES RECEIVED.

William Clark, The Nurseries, Wallington, Surrey.—*Catalogue of New and Choice Greenhouse and Hardy Plants.*

Ant. Roozen & Son, Overveen, near Haarlem, Holland.—*Catalogue of Bulbs, Aquatics, Terrestrial Orchids, Gesneriaceous Plants, &c.*

### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

IPSWICH.—July 6th, and September 17th. Sec., Mr. W. B. Jeffries, Henley Road, Ipswich.

FROME (Roses). July 6th. Mr. A. R. Baily, Hon. Sec.

NEWARK (Roses). July 6th. Mr. F. R. Dobney, Sec.

NOTTINGHAM. July 6th to 10th. Mr. A. Kirk, Municipal Offices, Sec.

SANDOWN PARK. July 6th and 8th. Mr. Wills, Royal Exotic Nursery, Onslow Crescent, South Kensington, Sec.

ALEXANDRA PALACE. Roses, July 7th and 8th.

WELLINGBOUROUGH. July 7th and 8th. Mr. W. B. Parke, Hon. Sec.

REIGATE (Roses). July 8th. Mr. J. Payne, Treasurer.

EALING, ACTON, AND HANWELL. July 11th (at Fordhook). Mr. R. Dean, Ealing, Sec.

ENFIELD. July 12th. Mr. J. T. Rofe, Bloomfield Nursery, Sec.

HELENSBURGH (Roses). July 12th and 13th. Mr. J. Mitchell, Sec.

WIMBLEDON. July 12th and 13th. Mr. P. Appleby, 5, Linden Cottages, Hon. Sec.

HIGHGATE. July 13th. Mr. W. M. Burck, 6, North Road, Highgate, Sec.

WEST OF ENGLAND (HEREFORD). Roses. July 13th. Rev. O. H. Bulmer, Cradenhill, Sec.

CLIFTON, BRISTOL (Roses, &c.). July 13th. Mr. J. T. Jackson, Sec.

LEEK (Roses). July 18th. Mr. S. Cartwright, Sheep Market, Leek, Staffordshire, Hon. Sec.

KILMARNOCK. Roses, July 18th and 19th. General Exhibition, September 14th. Mr. M. Smith, 11, King Street, Sec.

TONBRIDGE. July 19th. Mr. W. Blair, Hon. Sec.

ROYAL HORTICULTURAL SOCIETY, SOUTH KENSINGTON. July 19th and 20th (Roses, &c.). November 8th (Fruit).

THORNTON HEATH. July 21st and 22nd, and September 1st and 2nd. Mr. W. Raines, 10, St. John's Villas, Bensham Manor Road, Thornton Heath, Hon. Sec.

TWICKSBURY. July 25th. Mr. P. Moore and Mr. H. J. Cochrane, Hon. Secs.

WREXHAM. July 25th. Mr. J. B. Shirley, Hon. Sec.

HUNTINGDON. July 26th. Mr. J. Diller, Market Place, Sec.

HEADINGLEY. July 26th and 27th. Mr. T. Atkinson, Burleywood, Headingley, Leeds, Sec.

ABERDEEN (Royal Horticultural Society). July 26th, 27th, and 28th. Mr. Archibald J. Rennie, 123½, Union Street.

BRIGHOUSE. July 29th. Messrs. C. Jessop & E. Rawnsley, Hon. Secs.

SALTAIRE. July 29th. Mr. G. A. White, Hon. Sec.

KILSBY (Flowers). August 1st. Mr. C. E. Bracchridge, Sec.

HEWORTH (Horticultural). August 2nd. Mr. R. H. Felton, Hon. Sec.

RAWTENSTALL (ROSEDALE). August 4th and 5th. Mr. M. J. Lonsdale, Sec.

SOUTHAMPTON. August 5th and 7th. Mr. C. S. Fuidge, 39, York Street, Sec.

FRINEDON. August 7th. Mr. G. C. Mann, Sec.

TAUNTON DEANE. August 10th. Mr. F. H. Woodforde, M.D., and Mr. Clement Smith, Hon. Secs.

FILEY. August 11th. Mr. Walter Fisher, Hon. Sec.

OTLEY. August 12th. Mr. Alfred Suttle, Hon. Sec.

CLAY CROSS. August 15th. Mr. J. Stallard, Clay Cross, near Chesterfield, Sec.

WESTON-SUPER-MARE. August 15th and 16th. Mr. W. B. Frampton, Sec.

PRESTON. August 16th and 17th. Mr. W. Troughton, Hon. Sec.

SHEFFSLEY. August 16th and 17th. Admitt & Naughton, Hon. Secs.

NORTON. NEAR STOCKTON-ON-TEES. August 18th. Mr. C. Turner, Sec.

MIRFIELD HORTICULTURAL. August 19th. Mr. George Senior and Mr. John Rushforth, Hon. Secs.

CALNE (Wilts). August 22nd. Mr. H. Blackford, Sec.

NEWBURY. August 22nd. Mr. H. Seymour, Hon. Sec.

CHEPSTOW. August 23rd. Mr. R. Thorne, Hon. Sec.

SEATON BURN. August 26th. Mr. R. Richardson and Mr. W. Elliott, Secs.

CARSHALTON, WALLINGTON, AND BEDDINGTON. August 24th. Mr. J. Baines, Leicester House, Carshalton, and Mr. W. Clark, the Nurseries, Wallington, Hon. Secs.

ISLE OF THANET (MARGATE). August 30th. Mr. C. D. Smith, 8, Marine Terrace, Margate, Sec.

MONTROSE. September 1st and 2nd. Mr. Alex. Burnett, 2, High Street, Sec.

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (J. F.).—"The Elements of Botany," by Thomas Moore, published by Longman, will suit a young lady "anxious to begin the study of botany." (Glenmore).—Any bookseller in the town near you can obtain the book you need.

COMPOST FOR CYCLAMENS (J. T.).—Three parts fibrous loam, one part leaf soil or well-decayed manure, one part sandy peat, and a part of silver sand, well mixed and broken-up fine but not sifted, will be suitable. Drain efficiently.

FORMING ROOF FOR GREENHOUSE (E. M. P.).—We know nothing of the house you allude to, but if we understand your sketches aright the supports for the glass in the present case are lengthwise of the house, glazed without putty, and that you wish to convert it into an ordinary roofed house glazed with putty. You will require rafters, and these need not be more than 2 inches thick and 4½ deep, rebated half an inch wide and three-quarters of an inch deep for the glass, and between each of those you will require sash-bars 2½ deep and 1½ inch thick, rebated the same as the rafters. These may be morticed and tenoned into the ridge the depth of rebate below the ridge, and a piece of wood half an inch wide and three-quarters of an inch deep placed on the ridge between the rafters and sash to form the rebate for the glass. The rafters may be secured to the plates at bottom, and a fillet let in between the rafters and sashbars, bringing up the front level with the rebates, which should also project and form a nosing. You ought to have an opening for ventilation 18 inches wide the whole length of the house. Doing the work yourself it ought not to cost more than half of the sum you name.

WEEVILS ON RASPBERRIES (A Subscriber).—The insect you have sent is *Rhynchites alliarie*, which in some seasons attacks fruit-bearing trees of all sorts. It is very different from what is familiarly known as the Raspberry beetle, *Byturus tomentosus*. Evidently the visits to the young shoots are for the purpose of depositing eggs, and the only way by which it can be kept under is by the plan often pursued successfully with other weevils—spreading sheets under the Raspberries at night and gently shaking them. Also all twigs should be at once removed which appear to have been touched. The bark of the Vine sometimes affords a shelter to small companies of these weevils, and should be looked to wherever the species shows itself.

VINES MILDEWEED (A. B. P.).—Apply flowers of sulphur to all the parts affected—leaves, shoots, and bunches, admitting air more freely, repeating the sulphuring if necessary. Dress the border with guano, making the surface quite yellow, and wash-in with water at a temperature of 85° to 90°. The mildew has probably arisen from a too moist and close atmosphere.

COMPOSTS FOR PLANTS (R. A. C.).—The "Cottage Gardeners' Dictionary" gives the compost required for every description of plant. It may be had through any bookseller. If you only require a work treating of greenhouse plants, our "Greenhouse Manual" would suit you. It may be had from our office for 10d.

MELON CULTURE (A Young Gardener).—You may grow the Melon in a light part of the "moderately cool vinery," giving the plant or plants 13-inch pots, well drained, and using a compost of strong or yellow loam, firming well, keeping the neck or collar of the plants rather high in the centre of the pot, and leaving a couple of inches space for watering and top-dressings of manure after the fruit is swelling. Had you a frame on a hotbed of dung we should put out the plants, one in the centre of each light, with 10-inch depth of soil for the plants to grow in.

MARSHAL NIEL ROSE NOT THRIVING (A Subscriber).—The plant has not grown from the soil being so wet as to hinder the formation of roots. It is likely to do better in a bed of fresh soil, and will not be injured by the removal, only shade until established. We do not, however, advise this or any Rose to be grown in a house employed for Cucumbers. It will not long remain healthy, the atmosphere being too warm, close, and moist. Give it a chance in a cool airy house planted in a border of good material—turfy loam rather stiff, with a fourth of manure.

PLANT AND STRAWBERRY (S. B.).—The box was smashed. We can only say the plant is a *Pentstemon*.

GERANIUM LEAVES SPOTTED (A. Bland).—The air of the house is too moist. More ventilation will check the present spots, and prevent more appearing.

FUCHSIAS AND GERANIUMS NOT FLOWERING (G. H. H.).—Having only top light is the probable cause, and if so your only remedy is to place the plants on shelves close to the glass.

DRYING GRASSES AND FLOWERS (K. and J. B. A.).—Take some fine white sand (that called silver sand is the best), wash it repeatedly until all dirt is removed and the water remains clear. Next dry it thoroughly, and in a stick fresh-gathered flowers in their natural position, and afterwards cover them gently with the sand, taking care not to damage the petals. Now place the vessel in the sun or in a room where a constant fire is kept, and let it remain until the flowers are perfectly dry. Then remove the sand carefully, and clean the leaves with a feather brush. You must gather your flowers for this purpose when they are dry—that is, after the dew has evaporated. The process succeeds

best with single flowers, but the difficulty attending such double ones as Pinks, Carnations, &c., may be obviated by splitting the cup on each side, and when the flower is quite dry the incision made to adhere by means of gum-water; or the cup may be pricked around with a pin to let out the moisture. White flowers lose their natural colour by this process, but it may be restored by exposing them to a moderate vapour of brimstone; but crimson or scarlet flowers should be placed in a vapour of the solution of tin in spirits of nitre. The green leaves and stems are renovated by the vapour produced from a solution of steel filings in oil of vitriol. When dried the scent of each particular flower may be artificially renewed by dropping into the middle of it some of its essential oil; thus oil of Cloves will scent the Pink, oil of Roses the Rose, oil of Jasmine the Jasmine, &c.

**WHITE PINK (F. J., Dublin).**—There is one called Anne Bullen or Boleyn.

**BAMBOO UNHEALTHY (A. L. M.).**—We find on inquiry that there are this year many instances similar to the one you have noticed. An experienced correspondent states that as the plants become old they are apt to die off after the manner of old roots of Pampas Grass. He advises that all the small shoots of the Bamboo be cut away, leaving the few strong canes which may show some signs of life for another year's trial, subsequently transferring the plant to a fresh site and soil, when it may regain its usual healthy state.

**HAND PLOUGH.**—"G. M." wishes to know if it answers in a kitchen garden.

**MARKING LAWN TENNIS GROUND (Young Ponica).**—The only plan we know is to mix whitening to the consistency of whitewash with water and apply with a brush, drawing a line about 2 inches wide. It does not injure the grass, and is not obliterated by mowing, but becomes fainter each time, requiring renewal occasionally, and after heavy rain, which washes away the chalk mark. In mowing we take no account of the chalk line, simply taking up the poles and pegs with the net, readjusting them after mowing.

**KALMIA LATIFOLIA AFTER FLOWERING (Wimbledon Target).**—The plant should be placed outdoors in a sheltered situation, the pot plunged in ashes and duly supplied with water. Having flowered massively this season it is very unlikely it will not do so another year.

**PIPING REQUIRED FOR HEATING CONSERVATORY (T. P. R.).**—To heat 2450 cubic feet of air to a temperature of 45° to 50° in winter you will require 200 feet superficial of heated surface, or 266 feet of 3-inch piping. We have made allowance for your house being in an exposed situation.

**PLANTS NOT FLOWERING (Mark Manchester).**—Not knowing where they are, nor what they are, nor how you treat them, we can give no certain advice. Want of sufficient light is the probable cause of the deficiency.

**VINE LEAVES BROWN (A. B. C., Doncaster).**—If you water the roots abundantly you will prevent the leaves becoming brown.

**CELERY LEAVES GRUB-EATEN (Biceps).**—The grubs are the larvae of a saw-fly, *Tephritis onopordinis*. A drawing and description are in the first volume of this Journal. There is no remedy but picking off the blotched leaves and burning them before the grubs escape.

**WATERING (F. J.).**—The quantity of water to be applied in dry weather must be regulated by the soil and crop. No arbitrary rule can be laid down. Guano water is best applied in a clear state.

**LIME (H. J. B.).**—The common lime used by bricklayers is that applied. Mixed with the top 2 inches of the soil and sprinkled over the surface it will exterminate the slugs. Repeat the application if necessary; fresh caustic lime must be employed.

**FUNGI (J. A.).**—One of the forms of *Agaricus campestris*, and doubtless good for food. (J. M.).—The Vine leaves are covered with the black smut, which is known under the name of *Fumago*, and consists of *Cladosporium herbarum* and other moulds. There must be something wrong in the management of your house, or the leaves could not be in such a state.

**INSECTS ON CAMELLIA (S. C. Oakes).**—The white matter on the Camellia leaves is the exudation from the bodies of the females of a rare species of scale insect, *Coccus Camelliae*.—I. O. W.

**NAME OF FRUIT (James Radford).**—Alfriston.

**NAMES OF PLANTS (J. H.).**—*Lilium pyramicum*, a native of the Pyrenees. It is noticed in Parkinson's "Paradisus" under the name of *Martagon pomponianum*. (W. D. H.).—The Gum *Cistus*, *Cistus ladaniferus*. A native of Spain, and cultivated by Tradescant in his garden at Lambeth more than two centuries since.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### MANAGEMENT OF CHICKENS.—No. 2.

ALL the while the present hot weather lasts the chickens cannot have too much shade, and their food cannot be too fresh and sweet. Shade is important for all breeds. Cochins, and Dorkings, and Hamburgs are all the better for shade. With white varieties to keep them white it is essential. Those who only have bare and enclosed runs will keep them cool and fresh by watering them every two or three nights. It is quite surprising to find how the chickens are benefited by that practice.

We again urge that the yards should now be thinned, and all the inferior specimens removed to make room for the others. Cochins with scanty leg-feathering, or Cochins with heavy hocks and inside leg-feathering, can never be of much use. Hamburgs with white legs, Houdans and Dorkings with bad claws, single-combed and clean-legged Silkies, and all birds with such serious imperfections can never be up to the mark, and should be at once done away with. We are quite positive that many, too many, inferior and perfectly useless birds are annually allowed to live, and then perhaps sold for 3s. or 4s. each, and in their turn used by inexperienced purchasers as breeding stock, and hence come the swarms of perfect rubbish which we find advertised in cheap advertisements. These birds will, we fear, in time half ruin the fancy; and we often think the selling classes are in another way equally as unprofitable and damaging,

for to every good bird sold in a sale class we should think we may safely reckon there are ten bad ones. Weed-out, we say then, now the wasters—roast them, boil them, pie them, only get rid of them, and we dare say—we feel certain—the remainder will be doubly as valuable as if all had been allowed to live.

It is important now, too, to see to the roosting places of the chickens, for many will soon be changing their feathers, and overcrowding or bad housing may spoil the new plumage. Those which are allowed still to sleep in their coops—and we fully approve of the plan—should be carefully watched, for often a dozen or two will try and crowd into a coop which can only hold half the number. We like our chickens to sleep in these coops, when there is no fear of dogs or foxes disturbing them, as long as possible, for by moving these small tenements every day to a fresh place the ground is well manured, and the chickens are always in clean feather. Of course, only those who have a field or some such run can do this; but those who have the ordinary fixed houses merely for the chickens to roost in must keep such very clean, for just at this time many birds in one building, especially where any matter is allowed to remain and decompose, will fill the place with injurious and bad air. Boards under the perches which can be scraped every morning some use, but we like ourselves nothing so well as a bed of clean dust and sand, for it is so easily raked over with a finely-toothed rake, and the dust acts as a powerful deodoriser and removes every particle of smell. Some mix lime dust with this sand or road grit, but we do not approve of this where the birds can have access to the houses in the daytime, for they will often dust in it, and we are sure the lime injures the feathers and spoils some of the bloom and gloss.

Many who have a small plot of garden for flowers or vegetables, and also go in for chickens in quite an amateur way, are afraid of letting their brood loose in the garden, for a lettuce bed or young turnips or beetroots would soon cease to exist under the mothers' claws and the chickens' mouths. We should recommend them to have a few yards of galvanised wire and bend it loosely round the rhubarb bed, or when the strawberries are over round the plants there, or the artichokes and seakale, for they will now do no harm there; and we have seen a young brood of three or four weeks old thrive in a surprising manner when so wired-in, for they obtain shade, and the loose straws and refuse which are generally found on such beds afford a capital opportunity for scratching, and plenty of woodlice and flies and insects are being repeatedly turned up.

All will probably have by now cockerels and pullets large enough to separate. If only two runs can be spared for this purpose let the birds be changed in them frequently. The cockerels can have one run for a fortnight, and then the pullets can go there and the cockerels come to the "ladies' enclosure." The greater distance these runs are apart the better. We do not care for them being side by side and only divided by wire fencing. When, however, this cannot be remedied, let there be close hurdles or wattle fencing for about 3 feet high, such as we described in the "Basse-Cour" of Mr. T. C. Burnell of Michel-dever, for we do not desire the birds seeing each other through the wire.

The larger birds will not now want feeding so frequently. Birds four and five months old can well do now with three meals a-day, and three-months-old birds well with four. We again recommend at this period of their growth an abundance of vegetable food and not too much water. Bone dust some use very much, and we were much surprised to hear this last week from one or two celebrated fanciers how extensively they use it. We have never tried it ourselves, and yet we have sent to the exhibition pen a goodly number of winning chickens; but those who do care to try it, or who are in the habit of doing so, must see they get a useful sample, for we have seen some sent out which was simply perfect rubbish, and which would do about as much good as sawdust. Bones from the house, or, where the establishment is not large enough to supply any quantity, from the butcher, smashed-up and crushed on a wooden block by a heavy hammer, would prove of value we can well imagine; and that is the sort of bone-food, used, of course, in moderation and with judgment, which we should recommend and feel inclined to use ourselves.—W.

### DONCASTER POULTRY SHOW.

THE annual Show of the Doncaster Agricultural Society was held on June 28th, 29th, and 30th in Netherhall Park. The three days is sadly against the entries. The list of prizes needs revising, no Variety class being provided, while two classes are given for Dorkings.

Game headed the list, and a cup being given the quality was very good. In single cocks first was a grand coloured Brown Red, but rather excited, and evidently not used to the show pen; second a tall likely bird, but a little overshadowed; third a fair bird. Black Reds were mostly out of condition. First a grand moulded bird, with a fair hen; second a good-coloured cock, but a little high in tail. Duckwings not as good. The

first cock was very good, but the hen dark in eyes; second and third better hens, but cocks odd-eyed. Brown Reds very good, first and cup going to a perfect pair in fine order. Any other variety were all Piles. First the best cock we have ever seen; the hen was pale in leg, but these left no chance for any other. Second a fair pen; but third bad—old-fashioned with blotched legs and feet, but the only pen available. Silver-Grey *Dorkings* very good, as also Dark; the second largest, but cock lop-combed. The cup for the Hamburgs and larger varieties was given to *Spanish*, these being uncommonly good. In *Cochins* Buffs were first, Whites second, and Partridge third. *Brahmas*, Light, no third was given, but the two winners were fair pens. Dark very good. *Hamburgs*, Silver-spangles were good in most cases; the second-prize pen better in some respects than the third, but cock a little tilted in comb. Others very good, especially the first Silver-pencils. *Bantams*, Red, a large class. First-and-cup a grand pen of Black Reds; second Brown Reds, very good in colour; third old Black Reds, but the hen faded. In the Variety class was one very good pair of Piles; second of that colour were stylish; third Duckwings, a little faded. *Crève-Coeurs* and chickens a failure. In *Ducks* only the variety of any note, and some of the money previously withheld was awarded extra here. *Turkeys* were a grand class.

*Pigeons* were very badly provided for, and were shown in pairs, though the winners in each class were such as would come to the surface in more severe competition.

**POULTRY.**—*GAME.*—Cock.—1, H. E. Martin. 2, Holmes & Destner. 3, C. W. Brierley. *Black-breasted Reds.*—1, C. W. Brierley. 2, H. C. & W. J. Mason. 3, J. Mason. *Brown and other Reds, except Black-breasted.*—Cup and 3, C. W. Brierley. 2, Sales & Bentley. *Duckwings and other Greys and Blues.*—1, H. C. & W. J. Mason. 2, Holmes & Destner. 3, J. A. & H. H. Staveley. *Any other variety.*—1, H. C. & W. J. Mason. 2, J. F. Walker. 3, R. Walker. *DORKINGS.*—Silver-Grey.—1, J. Walker. 2 and 3, W. Roe. *Any variety.*—1, W. Arkwright. 2, J. Walker. 3, W. Roe. *SPANISH.*—Cup, H. Beldon. 2, J. Powell. 3, W. Rowbottom. *COCHINS.*—1, J. Walker. 2, H. Beldon. 3, A. Bamford. *BRAHMAS.*—Light.—1, J. F. Smith. 2, H. Beldon. *Dark.*—1 and 3, T. F. Ansall. 2, J. F. Smith. *HAMBURGS.*—Silver-spangled.—1 and 3, H. Beldon. 2, Holmes & Destner. *Silver-pencilled.*—1, 2, and 3, H. Beldon. *Golden-spangled.*—1, Holmes & Destner. 2 and 3, H. Beldon. *POLANDS.*—1 and 2, H. Beldon. *BANTAMS.*—Black-breasted and other Reds.—Cup and 2, W. F. Entwistle. 3, A. S. Sgden. *Game, any variety.*—1, Bellingham & Gill. 2, W. F. Entwistle. 3, R. Newbitt. *ANY VARIETY.*—Chickens.—1, J. C. & H. Elwis. *GUINEA FOWLS.*—1, F. Clater. 2, E. Snell. 3, W. H. Garforth. *TURKEYS.*—1, W. H. Garforth. 2, J. Walker. 3, G. Mangles. *who, B. H. Brookbank. Ducks.*—*Aylesbury.*—1, J. Walker. 2, W. Stonehouse. *Rouen.*—1, J. Walker. 2, W. H. Garforth. *Ducks.*—*Any other variety.*—1 and 2, A. & W. H. Silvester. Extra 1, J. Walker. *GEES.*—1, W. H. Garforth. 2, J. Walker. 3, J. White. *SELLING CLASS.*—1, J. F. Walton. 2, P. Powell. 3, R. Newbitt.

**PIGEONS.**—*CARRIERS.*—1, J. Walker. 2, J. E. Crofts. *JACOBINS.*—1, J. E. Crofts. 2, J. Walker. *ANTWERPS.*—1 and 2, W. F. Entwistle. *ANY OTHER VARIETY.*—1, J. E. Crofts. 2, J. Walker. A. & W. H. Silvester. 3, J. G. Knowles. A. & W. H. Silvester. *who, E. Crofts.*—1 and 2, W. H. Garforth. 3, J. F. Loversidge. 2, H. Yardley. *SELLING CLASS.*—1 and 2, J. E. Crofts.

**JUDGE.**—Mr. E. Hutton, Pudsey.

## PORTSMOUTH POULTRY AND PIGEON SHOW.

### PART 2.

HAVING looked through the 417 pens of poultry I next come to the 240 pens of *Pigeons*. The order in which they are placed in the catalogue is new, but hardly to be approved, for instead of the high-class varieties being put first—viz., Carriers, Pouters, and Tumblers, we have watted birds of all descriptions, the rule of nose being the guide, then Tumblers, and last of all—ah! name it not in Scotland—come Pouters. This is really too bad, for Pouters ought to be first of all rather than last of all.

*Carriers.*—Fulton and Maynard carried almost all before them in all colours save in Blues of 1876. An odd-looking mottled bird of Mr. Ord's won in Carriers any other colour. Dragons, far too much honoured by being placed next to the Carriers (depend upon it the Committee were all long-nosed men!), showed some good birds in all classes, but the Judge was very sparing of his highly commendeds and very highly commendeds. The White class was particularly strong, and I was glad to see it, for a White Dragon is one of the most elegant of Pigeons, and the two winning White hens were singularly elegant birds. In the Any other colour a good Red cock first, but the second not sound in colour as to tail, that great difficulty. Among the hens of this class a good Yellow of Mr. Baker's first, and Red, sound in tail, second. Of the Dragons of 1876 a good Silver second, and a highly commended Chequer. In a Show of 240 Pigeons there were over fifty Dragons. Truly this is a popular class in England, showing, I think, that elegance and a naturally-bred and good flying Pigeon has great attractions; for the Dragon is the naturally-bred Carrier, and I expect in very old days our best heavier Dragons would have been called Carriers.

Tumblers few, but very good. Cocks, a capital Kite of Mr. Baker's second. Hens, a Red Mottle second; a good Almond first.

Passing by Barbs and Fantails as deserving, I come to the Jacobins. First, a Red of Mr. Baker's, with the sides of the chain quite closing in whatever position the bird stood, and the hood neat and cap-like; second a Black, also Mr. Baker's, very good, with great length of chain; third Yellow and good in colour. Nos. 583 and 589 Red, good in colour. All the prize birds were somewhat large, and if they are to have length of feather in chain, &c., they must be large.

Pouters were not strong in numbers. Baker and Fulton won in cocks. In hens the same owners, and Mrs. Ladd third with an elegant-shaped, but not large-enough cropped bird.

In Any other variety, cocks, a grand Black Trumpeter first; in hens Mr. Baker won all, his White Owl being the best.

There was in a permanent building on the ground used, as I imagine, for a Drill Hall in inclement weather, a capital collection of English *Cage Birds*, and as we may well imagine at Portsmouth, a splendid lot of foreign birds. The Canaries almost smelt of pepper, and Goldsmith's line now bears a meaning and a signification he never intended—

"Who peppers the highest is surest to please."

Ecstatic spinsters and dowagers hovered in delight round the cages whether of English or foreign birds, according to their fancy, be that fancy turned to sprightly Norwich, neat Lizard, or high-shouldered Belgians, in the catalogue spelled Belgians; indeed, it was the worst-spelt catalogue I ever had in my hand, names of owners spelled incorrectly, and owners' names given to their dogs. Dun spelled "Dunn," Dragon "Dragon," Coppy printed "Poppy," &c. The printer's reader is clearly no fancier.

With a parting look at all sorts of foreign birds I go next to the *Rabbits*. First come the strictly fancy animals, the Lops, the best contrasting colours in the front—viz., the Black-and-white. Dear pretty "Bunnies," you carry my mind back to days when I kept you—days when my pockets were distended with marbles and tops. Now men and women delight in Rabbits—yea, as I see, soldiers and ladies. The excellency of the Lops must be apparent, by the fact that a buck (Mrs. Dressing's), with ears 22½ inches by 5½, got only a very highly commended. Getting away from Lops come the foreign varieties, one a huge giant weighing 16½ lbs.; then the small, neat, clean Dutch, and quaker-like Silver-Greys, Belgian Hare, and Himalayas, which look as if they had been indulging largely in taking black snuff.

In the same tent with the Rabbits are the *Cats*, thirty-three pens, naturally enough nearly all owned by ladies. No Tortoiseshell Tom was there, and not more than one female of that colour worthy of the name. Tabbies were better, among them a terrible cat and her three kittens, all of whom were double-jointed and had a hundred claws. Oh, dreadful kittens! If the little boy in *Punch* exclaimed with a rueful face of an ordinary kitten after some scratching experiences, "Mamma, has tittens pins in their toes?" what would he have said of you, you dreadful kittens? Of other and more proper kittens there was a nice entry, among them a Blue Tabby (869), and a Silver Tabby (865), which pleased me greatly. There was, too, another rather dreadful kitten having twenty-six claws—*i.e.*, eight more than it ought to have, and some long-haired Cats always thin from their life-long labour of keeping their long hairs clean, for Fuss in health will always be clean at whatever cost of trouble and saliva.

Next to the Cats come *Guinea Pigs*. Well, and why not? they please the boys and girls, and with a prize will be doubly pleasing. Guinea Pigs have got up in the world, and now, like St. Bernard Dogs, boast of two varieties, the rough and the smooth, the former called Abyssinian. They are in colour like the English, rich tortoiseshell, and the growth of their hair is very curious, for not only is it rough, but it grows in a series of rosettes, not very unlike the rose in a Jacobin Pigeon or a "feather" in the coat of a horse. The little animals seem to carry targets on their sides to be shot at, with a prize for whoever hits the bull's-eye. These little Abyssinians are quaint-looking rather than pretty.

Across to another and larger tent containing the *Dogs*. Although the attendance, especially at the early part of the day, was very small, yet such is an Englishman's love for a dog that everyone, I think, found his way into this tent. There were a little over two hundred animals exhibited, and the strength of the Exhibition was in the Newfoundland, which were indeed well worth seeing. Next to them in excellence were the Blenheim Spaniels. The Fox Terriers seem to me to be growing more and more Beagle-like; and some dogs entered as White English Terriers were simply Bull Terriers. The Wire-haired Terriers were numerous, and No. 1000 was no doubt the real thing; a great Pigeon fancier, strange to say, was his owner (Mr. Maynard), and another great Pigeon exhibitor took first in Black and Tan Terriers (Mr. Fulton). Know a Pigeon know a dog, it seems.

Specially to be spoken of was the life-saving contest. A dummy sailor was made which at a distance a man even might mistake for another man. This dummy was thrown from a boat moored 200 yards from shore, the competing dogs were on land, and each in turn let loose when the dummy was thrown overboard. I made the acquaintance of the hero of the first day—viz., "Monarch," a black Newfoundland of noble presence, who swam direct to the dummy, seized it, and at once brought it to the shore; this done in about a minute and a half. This beautiful dog is owned by Mr. T. Loader Browne of Chard. He was second at Birmingham when about a year old. He measures 21 inches round the head in front of his eyes. On the second day a Retriever, I believe, was first and a Newfoundland second.

This life-saving contest strikes me as a most meritorious scheme, and deserves strong support. At Portsmouth are thousands of arms made on purpose by man to destroy man's life; and at Portsmouth the wiser dog showed his power and desire of saving man's life. Surely such a contest on a large scale might be carried on at various seaports and towns. Brighton abounds with dogs, people, and money, why not have such a contest there? Rinking is too hot for summer, while the very sight of the dogs in the water is cooling, to say nothing of the grand purpose for which the contest takes place. Train Pigeons by all means to carry our letters, if a day of terrible need should come, but train dogs also to save our lives. The instinct is in the noble animals, it only wants cultivating.—WILTSHIRE RECTOR.

### TITLARK OR WOODLARK.

In answer to "T. H. Y." the Titlark, which is 5½ inches in length, is the smallest of the Lark tribes, being half an inch shorter than the Woodlark, which more resembles the Skylark in figure and appearance although less in size. The Titlark has two bright bars upon the wings, the throat is pale and not speckled, and above each eye there is a bright stripe. The beak is very pointed, the upper mandible being dark brown, and the lower one whitish; the nails of the back toes are crooked, and the tail narrow and rather forked. The Woodlark's beak is black above and brown beneath, merging into flesh colour towards the tip of it. The head feathers, which are longish, give a broad appearance to the bird's head, and somewhat resemble a crest when the bird is under excitement. Around the head from eye to eye appears a whitish-grey mark, and the feathers about the cheeks, throat, neck, and breast are whitish-yellow with black-brown spots. The coverts of the wings dark brown, with a pale reddish-brown margin. At the joint of the wing, the shoulder, and the four first coverts there is a white spot. Tail feathers broad, black-brown, the first and second with a reddish-white conical spot, and a white tip; the two middle feathers entirely greyish-brown.

Titlarks so change their places of resort that to gain a knowledge of the various kinds of food they pick up would puzzle a Philadelphia lawyer. Their places of resort are woods that abut upon arable land, with gardens and meadows adjacent thereto; places, also, where timber has been felled and rooted up. In or about the beginning of autumn they visit fields planted with cabbage and other vegetables; somewhat later on they resort to eat fields. As we cannot, therefore, name "all the things" they eat, we will state a few—for instance, gnats, grasshoppers, flies, caterpillars, small butterflies, and when in confinement, German paste, crushed hempseed, and unflavoured curds. It is better to frequently vary their food, for they are somewhat delicately constituted, and if in confinement they are not at once supplied with a nutritious diet, such as mealworms and ants' eggs, they will quickly show signs of declining health. When they are first taken it is somewhat difficult to treat and accustom them to food. If anything will tempt them it will be mealworms and ants' eggs. Do not give Canary seed to your Titlarks. We cannot help here recording the fact that at an exhibition at Birmingham some two or three years back, the only food a Thrush had in its food-trough was Canary seed! and we could not help fancying that the Thrush appeared much puzzled whilst surveying the strange food supplied to him.—GEORGE J. BARNESBY.

### SYSTEMS OF MANAGEMENT.—No. 4.

AFTER advertizing to swarming, nading, and eking, we now come to supering.

Supering is a mode of enlargement well understood by all classes of apiarians, and when successfully done gives satisfaction, for both the bee-farmer and the amateur feel enriched by the possession of some well-filled supers. It is an ancient practice, and was partially adopted long before my day. What I mean by partial adoption is this, that those who used supers tried other ways of enlarging hives, and wisely so, for supering in many cases does not answer at all. All hives that admit of enlargement by supers only are faulty and imperfect.

1, Supering on the non-swarming principle consists in placing supers on hives as soon as they are full of bees, and when the supers are filled they are taken off and empty supers are put on in their places. This system is open to many objections, two of which may be noted here—namely, the uncertainty of success and the risk of losing swarms.

2, Supering on the swarming principle is resorted to in a great variety of ways. Sometimes small supers are obtained from hives before swarming—that is to say, as soon as the supers are full they are taken off, and the hives are swarmed at once artificially. The swarms are put into 16-inch hives, which in fine weather they fill in about three weeks or a month, when they should be supered. The mother hives, too, may be ready to fill supers by the end of three weeks from the time of swarming if no

second swarms be taken from them. On both mother and swarm hives supering may be continued till the end of the season without much risk of losing swarms. We have obtained 30 lbs. of super honey from swarms put into 18-inch hives, which hives hold and yield more honey than the 16-inch hives. In 1863 Mr. George Fox had two supers above 100 lbs. each from two non-swarmers, and one super of 90 lbs. from a swarm hived late in June. Hives on which supers have been filled are too full of honey for stocks, and yield, according to size, from 25 lbs. to 50 lbs. of run honey. We take, and advise others to take, the honey from heavy hives. If stocks be wanted, the bees from these hives could be driven into empty hives and fed with sugar syrup. Both honey and better stocks are thus obtained.

In all cases of supering, pieces of guide comb (white drone comb) should be used to entice the bees to enter and commence working at once. These pieces of guide comb should be cemented to the crowns of the supers, and small wooden ladders about as thick as a child's finger should be fixed between the crowns of the hives and crowns of the supers to enable the bees to ascend and begin at the top.

It should be borne in mind by all apiarians that bees like to swarm every year, and in hot seasons first swarms are prone to send off virgin swarms; it is therefore desirable to prevent hives with supers on them from becoming too full of bees. In the spring and early summer months bees multiply rapidly, and may cluster at their doors before supers on their hives are quite full. We never like to see bees clustering and wasting their time on the outsides of their hives. By raising the hives 2 or 3 inches by ekes, clustering is prevented and more work is done inside. When the season is nearly over and supers nearly filled it may be desirable to avoid eking, that the bees may well fill and finish their supers.

Last autumn something was said in this Journal about the American practice of supering with small boxes. Boxes containing 4 or 5 lbs. only of comb are there more readily sold than larger boxes; and the Rev. Mr. Blyth suggested two years ago the desirability of offering prizes for the greatest weight of super honey from a hive under any system of management. I then resolved to try what could be done this year in filling supers from a stock hive and its swarms. I marked my largest and best hive for this experiment, but, unfortunately, the queen of this hive died in autumn or winter, and the whole affair came to grief. This season, too, has been unusually unfavourable for bees. Till the 17th of June bees have been unable to find food enough for themselves here. On the 18th day of this month the wind veered round to the south (from the north), and the bees began to work in earnest. I weighed two of my hives on Monday morning the 19th, and again on Tuesday night the 20th. One hive gained 14 lbs. and the other 13 lbs. in the two days. To-day the wind has been high, and a thunderstorm has stopped outdoor work. In this contemplated experiment or effort to fill a number of small boxes with honeycomb my plan is to follow the usual mode of management till the end of the season. For the sake of clearness let us take a strong stock to begin with. The first swarm from it would be put into a 20-inch hive containing about 5000 cubic inches of space; and the second swarm or cast would be put into an 18-inch hive containing upwards of 3500 cubic inches of space. At the end of three weeks from the time of first swarming the bees would be turned out of the old stock into another 18-inch hive. Thus we should have two or three large swarms at work in large hives, and the parent hive with its honey put aside till autumn. Swarms in large hives capable of producing from 100 lbs. to 250 lbs. each would work in a satisfactory manner as long as weather and store-room would let them. "How, then, could you get supers?" That is the question and point we are coming to. In such swarm hives we find at the end of every honey season large stores of honey, and the great bulk of it stored in pure virgin comb. In taking the honey from our hives in the autumn we put the discoloured combs in earthenware or milk pan for running, and the pure virgin honeycomb is placed on dishes and in clean empty hives. Sometimes we have cut the discoloured combs from the centres of the hives and sold the virgin comb in them in its natural state; but our usual mode is to empty every honey hive and put aside the virgin honeycomb for sale at 1s. 6d. per lb., never less than 1s. 3d. per lb., and we can sell it thus as readily and at as high a price as in supers, but in supers it is more easily carried and looks better.

Now let us come to the projected experiment or supering process. The bees, of course, are driven from the honey hives into empty hives, and all the white pure combs, both full and empty, go to fill small boxes. The boxes with holes in their bottoms would be filled as well as human hands could fill them with the combs as they are taken from their hives, leaving room enough between the combs for the bees to work, for the combs thus placed would require refixing, repairing, and some cells refilling by workmen more clever than bee-masters. Supers thus filled and retouched and completed are both seemly and saleable. "But why use combs that are empty or partially filled in this artificial process?" Because it is desirable to use up every bit

of white comb and fill as many supers as possible, and because the bees make a better finish with combs unsealed than they do with sealed combs. "But how can they fill and finish after the honey season is over?" As soon as all the combs are partially fixed in boxes their lids should be nailed or screwed on, and then placed on the tops of the empty hives containing the swarms. By giving the honey of the discoloured combs to the bees they would soon commence carrying it all into the supers. Thus all the honey gathered into the large hives may be transferred to either large or small supers. "All this is very artificial, and might disqualify for competition." It is artificial, but we are in search of a system that will give the greatest results in super honey for market or home use, and experience has taught that more honeycomb may be obtained from large hives managed on the swarming principle without the complication of supers than from smaller hives supered throughout the season.

Like the Rev. Mr. Blyth we are on our way for the largest amount of pure honeycomb, and if any of our readers who have hitherto been living in the land of hope will condescend to join us in our march they will be conducted across the frontiers into a land of success.—A. PETTIGREW.

## OUR LETTER BOX.

**CHICKENS DYING SUDDENLY (E. L. P.).**—Have your chickens the run of the lawn, or only the space enclosed by the coop? If only the latter they will die as they get older, and they have neither room nor food enough. If they have been kept in let them out; the hen need not go with them, and they will do no damage. There is nothing wrong in your feeding if we except the rice. As they were probably all together, lightning if it killed any would have killed all. We believe if they have their liberty there will be no return of the mortality.

**EGGS BROKEN IN LAYING (Marks, Manchester).**—As they are shell-less it is evident that the egg organs are disordered. The hens are overfed. Give them less food both in quantity and quality. Let them have bricklayer's rubbish, and give each a dessert-spoonful of castor oil.

**CANARIES FAILING TO BREED (Inquirer, New Ross).**—If your Canaries have been properly matched we see no reason why they should not have bred before this. There has been some defect in the mode of treatment to a certainty. There is little chance of the birds breeding this season, although you can further exercise your patience by keeping the pairs separated in the breeding compartments until the end of this month. If the birds have not moulted out of their proper season (the autumn) they should have bred; but if they have been kept in an artificial temperature, occasionally casting or throwing off odd feathers, they have not been in condition to breed. In the absence of further knowledge as to your general treatment of the birds we cannot assist you as to how to proceed in the future, although we should have been pleased to have given you assistance.

**MOOR HENS, OTHERWISE WATER HENS (E. B. M.).**—Young Water Hens leave the nest to follow their mother soon after they are hatched, and no doubt they feed upon the same kind of food as their parents, which consists of worms, insects, portions of aquatic plants, mollusks, and the smallest of fishes.

**EXTRA HIVE ROOM (—).**—No doubt bees will frequently work downwards through a hole such as you describe, but we have never found it answer. We prefer the open eke, or better still the use of supers, where free access through wide and extensive openings is afforded to the bees of a stock. Our friend "B. & W." wrote something on this subject not very long ago in this Journal. We refer you to his article.

**BEES SWARMING IRREGULARLY (Jane M.).**—Irregularities in swarming such as you describe are not uncommon with bees. You have treated the two second swarms which issued the same day quite right. We should have done exactly as you have done. Probably the queen of the one which returned was imperfect, or else too quick in her movements for the bees to find where she alighted. We ourselves once picked up a queen which the bees had failed to find.

**NADIRING (Amateur).**—If both honey and stocks be wanted from early swarms, hives or nadirs may be placed beneath them as soon as their hives are filled with combs. The bees readily build combs in the bottom hives and carry most of the honey into the upper ones. The same thing may be done with stocks that have not become ripe for swarming before the end of June or thereabouts. When the topmost hives are removed for honey their bees are driven into the nadirs. As bees like to swarm, and instinctively prepare for swarming by building drone combs before swarming, it has been found that they very often build too much drone combs in nadirs, especially those that have not swarmed, and therefore eking and supering are preferable in most cases to nadiring. In all cases of nadiring the bees should be made to enter and in by one door in the bottom hive.

**ARTIFICIAL POLLEN (J. F.).**—We have never tried this pollen, but it seems to meet with decided favour at the hands of many able bee-keepers who have tried it. We do not quite understand your question. Do you wish to give each hive a separate dose of this pollen? If you wish to supply it *en masse* you cannot do better than others do. Take a common straw skep, fill it with fine shavings, and the pollen mixed with it; and put all under an open dry shed, close at hand. Try Brown & Polson, and report your experience.

**DRIVING BEES (Wm. Talbot).**—You will do well to turn the bees out of your old hive and put them into a larger one, and the sooner you do it the better; indeed, it should have been done on the 20th of June before the young queen in the hive began to lay. You will probably find brood in the combs, which will be lost, but this cannot be prevented if you drive the bees now into a larger hive. Drive the bees first into a small hive, and then shake them into the larger one. If you have not a small hive to fit, roll some haybands or towelling cloths round the mouth of the old hive, so that the larger hive may rest on them and not slip over the sides of the old one. All that you want is a little more courage. In cases like yours we have taken our coat off and tied it round the mouths of hives to make them fit in artificial swarming.

**EXCESS OF SWARMS (Thomas Meattlin).**—The Isle of Wight is a good place for bees. From a very heavy hive you had a natural swarm on the 18th of May and an artificial one on the 26th of June. You have put a super on the old one to prevent it from swarming again, and you intend to super the first swarm by the end of this month. You should not have attempted to take a second on the 23rd and 26th of June. On the 23rd the swarms went back to the parent hive because the queen was left behind, and on the 26th you took the queen with the swarm, and thus made the old hive queenless, and if the young queen which you took with the swarm has not begun to lay the old hive is queenless still. But probably she had begun to lay before her removal, and the bees may be now rearing another. It would have been better to have turned out all the bees from old one at the time and taken the honey; thus you would have obtained two good swarms and hive full of honey. Bear in mind that a second swarm can be taken at one time only—namely, when there are more than one queen in the hive, or, in other words, at the piping season. You will not get a super filled on the old hive this year, so you may remove it and put it on the first swarm. Examine the combs of the old hive at once to see if they contain any brood, and if the cells are empty your better plan will be to drive all the bees out and unite them to the second swarm. Beginners run great risks in attempting to take second swarms artificially; not so with first swarms.

## REMARKS.

28th.—Thick fog all night and till 9 A.M., then very fine till 5 P.M., when it became dull and cloudy; thunder at 6.10 and 6.55, and storm-like during the remainder of the day.

29th.—Very fine all day, but looking storm-like in the evening, and very much cooler than it was yesterday.

30th.—Fine, but at times rather cloudy and cool; slight rain between 9 P.M. and midnight.

July 1st.—Dull and cloudy all the forenoon, but very fine evening and night.

2nd.—Rather close and warm all day; though there was but little sun.

3rd.—Dull morning; very storm-like about noon, but fine afternoon and very fine evening and night.

4th.—Dull all day, at times particularly so, but the evening rather more bright.

Temperature very nearly the same as last week, only a few drops of rain, but much cloud. Sun very powerful on Sunday the 2nd.—G. J. SYMONS.

## COVENT GARDEN MARKET.—JULY 5.

OUTDOOR fruit is now putting in a good appearance; in fact, the Strawberries grown near home are now at their height, and are being followed by a large supply out of Kent and Essex. Cherries bid fair to be light crops, while Raspberries show want of rain. Hothouse fruit is quite equal to the demand owing to the moderate amount of business now doing. Prices generally lower.

From observations taken near London during forty-three years, the average day temperature of the week is 74.9°; and its night temperature 50.6°.

## AURICULAS.

N no account should your correspondent "J. T. D. L." put his trust in chance-saved seed for raising florist Auriculas. In the first place, the quality would be dismally obscure in comparison with that which may be obtained from known and chosen parentage on both sides. Even the quantity would be uncertain and small. The Auricula is flowered in a quiet though free air. Bees about it are an abomination, and every in-

sect trespasser is prosecuted with the utmost rigour, so that the agencies of wind and winged insects in fertilisation are withheld from choice Auricula blooms. Seed is therefore best and most abundantly obtained from studied crossing, and the florist is very thankful for the rich opportunities he has in plants so secured from intrusion.

The pleasures of raising seedlings are manifold. The crowning one, of course, is the final result; but the choice of parentage, the careful fertilisation itself, the watching of the swelling pods, the harvest of the seed, and the diverse growth of the young plants, are all matters of deep interest. The more completely each florist makes these operations the work of his own judgment, hand, and eye, the more thoroughly will he understand and value and enjoy the result. Herein, indeed, is one's own experience the sweetest. Herein do even disappointments "pay," for whatever you miss, you fail not in great variety and beauty.

In saving Auricula seed it is important to begin with the flower when young enough. The stigma is not fit for impregnation until it is viscid or slightly gummy. By this natural provision the light pollen grains are enabled to adhere to it. It soon, however, loses this dew of its youth—soon, indeed, after the pollen of the anthers is past its abundance. Before these anthers can burst I remove them from a flower I wish to fertilise, and this will be before it is well open. I watch the stigma, and when it becomes fit I apply a well-dusted young anther from a bloom of the variety I wish to cross with. I have discarded the use of camel-hair pencils; for pollen is a very subtle substance, and in spite of care there is a possibility of mixture by brush-work, whereas nothing is so pure as a virgin anther. When the stigma is covered with pollen it may be expected that the parentage of the seed is tolerably safe, since the stigma has been pre-occupied, and its powers pass away when its work is done. I use a pair of very delicate nippers, fine enough to lay hold of a single anther and to pass down the throat of the flower to the low-lying pinhead or stigma within.

It is no matter-of-course that crossing properly performed is effective. The plants may refuse to bear seed, something untoward occurring leading to a failure or poor crop. Auricula seed is a breakdown with me this year, although I took pains in every way. Spring was a most vexatious and hurtful time, and no florist could read any poetry about it with patience and without feeling it all mere works of fiction, untrue to nature.

If your correspondent has no other green edges than those he has named his disappointment among them is attributable to his apparent lack of the best varieties, which are so difficult to meet with. Prince of Wales is the best he mentions, and it is often awkwardly crumpled. When he can obtain Freedom, Champion, Col. Taylor, Prince of Greens, and Anna his eyes will be gladdened with beauties that do not often disappoint. As to Lancaster Hero coming green-edged, he should rejoice when it does so, and he will grow accustomed to see it bloom in that choice character from a truss that is formed before the spring growth; but the variety is normally a grey edge, and one of our most dashing ones.

I should say he might fairly hope to succeed with the Auricula in rural Wales. Some growers would very gladly exchange their difficulties for his, and take a pure though rainy climate in return for their dingy, dewless, poisoned town atmosphere. The Auricula rejoices in fresh upland air and clear breezes from the moors. But the damp that is fatal to it is not the moisture of a plentiful rainfall, from which it can be protected; "the enemy" is the unnatural dampness and stagnation of ill-ventilated frames, and the sour marshiness of an ill-drained soil.—F. D. HORNER, *Kirkby Malzeard, Ripon.*

## PEACH BLISTER.

WHEN the expanding foliage of the Peach is exposed to the influence of frost or cold cutting winds it becomes blistered—not shrivelled—pretty much in proportion to the cold or exposure to which it is subjected; the affected part changing from its normal colour to a pale green hue, thickens and swells, becoming larger with the growth of the leaf, the outer surface often becoming very rugged and irregular, and upon this a delicate mould or fungus makes its appearance in due course, but not till the blister has been established for some time. This is what close observation extending over many years has taught me. Let those who say that fungus is the cause of this blister explain the process, and prove to demonstration if they can how and why it does so, and in doing so let me ask them to keep to Peach blister alone and not wander off to other forms of disease; in a word, let them give us facts and not fancies.

Mr. Smith evidently confounds blister with curl caused by the attacks of aphides upon the under surface of Peach leaves causing a contraction of the tissue: hence the curl. I am aware that this curl affects other trees in precisely the same manner and from the same cause; but let us confine ourselves to the Peach leaves. If an argument is sound it needs no foreign support. Curl is often present in the foliage of Peach trees growing under glass, but blister is never found in a well-managed house. Mark! I say "well-managed" advisedly, because a little mismanagement of the ventilators during the prevalence of a cold wind induces blister to appear even with "great virulence." Many examples might be quoted, but one will suffice. I was once asked to examine a rather bad case of blister under glass, and found that all along the house immediately under the ventilators the foliage was

much blistered. Traces of the scathing power of the cold air were visible in other parts of the house, but nowhere was there so much affected foliage as in the direct line of the ventilators; thus showing plainly the source of the mischief and its remedy.

Mr. Smith alludes to a form of Peach blister quite distinct from that arising from cold. When and where does this occur? Upon what form of Peach tree, and under what circumstances of climate or cultivation? I have cultivated the Peach successfully under a variety of circumstances and not a few difficulties, and so far I have met with but one form of blister.

To own, as Mr. Smith does, that "the east wind will shrivel and wither all sorts of leaves and prepare them for the attacks of all sorts of fungi," and then to add, "but this is quite beside the question," is to show that he has failed to grasp its meaning or to appreciate its full significance.

The questions asked in the first paper on this subject were simply, "What is Peach blister?" and "What is its cause?" In replying to these questions I showed that the foliage of trees exposed to cold winds became blistered, while that of the trees sheltered from the cold remained perfectly healthy; my aim being to enforce the importance of such shelter, and thus avoid the recurrence of a scourge of such deadly virulence. That is the question, besides which the matter of the fungi assumes quite secondary importance. Mr. Smith believes that fungi is the prime cause of Peach blister and not its result. He is entitled to entertain that opinion, but I consider it is in opposition to the plain teaching of facts.—EDW. LUCKHURST.

### ABOUT MELONS.

It is always a time of anxiety both to amateurs and professionals when Melons are setting. The fruit though apparently setting does not swell but turns yellow, and unless care be taken to have all the fruit upon a plant set together, the first set fruit takes the lead and appropriates all the support of the plant to itself, the others not swelling but turning yellow, though they may for several days remain green but stationary.

I can account for the non-setting, it being invariably associated with a defective root-action—want of warmth and moisture in the soil, with a too close, moist, and not unfrequently cold atmosphere; but for the uncertain and irregular swelling of the fruit I have more difficulty in ascertaining the cause. In some of the older types, as the Cantaloupe in scarlet-flesh, and the Musculatum in green-flesh Melons, I have noticed an occasional fruit not starting with the first set, yet swelling off freely. I have often thought if a free-setting kind, when the first crop was half swelled, had another crop of two or three fruit per plant, that the value of Melons would, especially to those with but a two or three-light frame, be considerably enhanced. A good succession would be had without the means of resorting to a second bed.

I have noted all kinds with a tendency to give successional fruit. I do not mean one crop to ripen and then succeeded by another setting after the first were ripe; but with the first fruit swelled fifteen to twenty days, other fruits followed—perpetual bearers in fact, so far as annuals can be such. Little Heath gave some hope from an occasional fruit of this description, but though its flavour was fair it was not likely to command favour with those having heat. Read's Scarlet Flesh gave proof of its free setting and continuity of bearing, but the secondary fruit were so small as not to be of much worth. Victory of Bath exhibited a disposition of this kind, also Beechwood in the oval form, which is a very free setter, and does not net much. There is another form of Beechwood perfectly spherical and beautifully netted, which is not a good setter, being very impatient of moisture, the plant being much given to damp at the collar. This is not a good second-crop sort nor a successional bearer, but being a great favourite I still think it unsurpassed in green-fleshed Melons when it can be kept in character, it being apt to degenerate or revert to the oval form, which is not good in any respect. Oulton Park (Wills) also gave evidence of intermediate bearing, but the secondary fruit, as with Read's, were so small as to be underserving attention.

Now, seeing the intermediate fruit of Read's were small, I crossed Beechwood therewith; but though I have a plant less susceptible of damp, the fruit setting very freely, swelling splendidly to a good size, round as a ball, without a trace of rib, and netted all over without a core, seeds embedded in the

flesh, pale rose colour, yet not a sign is given of perpetual bearing.

Golden Gem × Read's has given a smaller fruit than either of those with a white flesh, the fruit ripening off golden as in Golden Gem, and being well netted. It may, however, be grown to a size of 2 to 3 lbs., with three to four fruits upon a plant; but I have it this year with eight, three of which are intermediate fruit. The point sought is, therefore, to a certain extent gained, also an increased hardness of plant, which is one of the greatest desiderata in Melons. Victory of Bath, as before stated, exhibits a tendency to perpetual bearing, and the result of a cross between it and Beechwood has given us Easton Castle, which possesses the vigour of Beechwood and its deeply-lobed foliage. It has also the same tendency as the last-named to damp at the collar. The fruit is oval and slightly netted, but excellent in flavour. Now, this is one of the freest-growing and setting of all Melons, and a certain (so far as two seasons' experience of it verify) and continuous bearer. I have only two plants (for I do not grow named sorts except a few plants for impregnating), dependence being placed upon crossbreds, and of these two plants have respectively five and four fruit of the first swelling, and four and three of the second, respectively. The secondary fruit will apparently swell to a size superior to the first crop. The secondary fruit are twelve to thirty days later than the first crop—thus a bed planted at the close of March or early April will have the fruit set in about six weeks, and the fruit ripe about the end of June or early July, and the last of the secondary fruit will not be ripe until early August. It may not be a fixity of character, but it appears to be so, and in that case it will be highly valuable to those who do not care to have the fruit all ripe together, but are desirous of a continuity of bearing—the fruit ripening at intervals.

Varieties of Melons are being extended annually, the main object apparently being to impart flavour to bulk without taking into consideration other advantages, particularly that of hardness. Could the flavour of our best heat-requiring kinds be implanted in a plant that would succeed in a cold frame it would be a boon to many who cannot command heat, as well as advantageous to those who can.—G. ABBEY.

### NERTERA DEPRESSA.

As information is sought on the cultivation of this remarkable and exceedingly ornamental plant, I may briefly detail my experience. I have grown it now for four years, and each year I find that the less I shelter it the better it flourishes. If it is not entirely hardy it is very nearly so, and certainly all the shelter that is needed to protect it in winter is the glass of a cold frame.

I at first failed with this plant, as many have failed, by placing it in a temperature too high for its nature, when it grew spindly and eventually dwindled away. I was afraid also of watering it overhead lest it should "damp-off," but experience has taught me that the plant is not nearly so delicate as its looks imply. I now permit it to have frost and snow in moderation and rain without reserve, and I am rewarded with healthy plants laden with brilliant orange-scarlet berries. I am indebted to the "Botanical Magazine" for suggestions as to the right mode of culture, having found it there stated to be "a native of the bleak cold antarctic mountains, and found also on the mountains of New Zealand, and on the Andes from Cape Horn to New Grenada."

It does not grow more than 2 inches high, and produces its Red Currant-like fruits to the number of more than a hundred on a few square inches of surface. For rockwork it is a charming plant, and for the front row in a light and cool greenhouse it is a gem ever to be admired. Its culture is of the simplest, and it is a plant which almost all who own a garden may grow successfully. It is not at all dainty as to soil; but a compost in which it grows with great freedom is equal parts of loam, peat, and bruised charcoal. The great point is to afford it plenty of water—in fact, with good drainage too much water cannot be given to established plants.

There can be no better place in which to grow it than a very light cold frame, the pots to be plunged in ashes. This is very important, for if not plunged the soil will become dry at some time or other, and the plants will then inevitably lose vigour. The lights should be removed from the frame during fine nights, so that the plants can receive the benefit of the dew, and also during the day when heavy showers are not prevalent—not that the rain will do serious injury, but by

splashing the soil over the plants they are rendered somewhat unsightly.

I read last year in the Journal that this plant was employed by Mr. Legg of Clapham for purposes of carpet bedding, it being associated with *Sedum glaucum*. I considered that a valuable hint, for I cannot conceive a combination more chaste yet more brilliant, and I shall report progress of the growth of these two lovely hardy plants for garden decoration by-and-by.

At present my plants of *Nertera* are just showing their insignificant pink flowers in profusion, and I am sanguine that a rich crop of fruit will follow. These plants were wintered in a cold frame, the glass having had no covering, and since March they have been plunged in ashes in the open border, receiving no protection whatever. Other plants grown under glass are about perfecting their berries, and I cannot imagine any low-growing plants more conspicuously beautiful.

Plants are readily increased by division, keeping the plants regularly and continually moist; also from seed, sowing as soon as ripe in a damp shaded frame, never permitting the soil to approach a state of dryness.

The three prime essentials in the cultivation of this plant are coolness, light, and water. With a bed of ashes in which to plunge the pots, and a hand-light or frame to afford shelter in severe weather, anyone may grow *Nertera depressa* if he will but water it freely.—W. B. J.

## NOVELTIES IN THE ROYAL GARDENS, KEW.

*MECONOPSIS WALLICHI*, on account of its high reputation as a beautiful plant and from its long absence from cultivation, is of the greatest interest just now on the rockwork. In our issue of June 11th, 1874, we gave an account with a figure, and to which we must now call attention. It is there said to be "remarkable as being one of the very few plants, if not the only one of the order, with blue flowers. It was discovered in the Sikkim Himalaya by Dr. J. D. Hooker, who sent seeds to the Royal Gardens, which produced flowering plants in June, 1852." This plant is about 2½ feet high, and the leaves and stem have a very yellow appearance, from which one would almost feel sure of a yellow flower; indeed, until the last few days it was supposed to be *M. nepalensis*, a tall species with yellow flowers that has also been in bloom. It cannot be said that this is anything like the celestial blue represented; the colour is, in fact, slightly inclined to purple, and not at all bright. This is possibly a very poor representative in point of colour, and we shall hope that such is the case until evidence is given by other specimens.

Its cultivation has been considered difficult, though that does not seem really to be the case. Seeds sown in a cold frame have come up well—far better than others with slight heat. The young plants have had no inclination to die during winter, either in pots under glass or planted out on the rockwork. It seems much the best to plant out as soon as the plants have become established after the first potting-off, and it might even be better to prick-out in the final position from the seed pot. A full supply of moisture both at roots and top is evidently essential, and this is perhaps the secret of success. A rather shady position will be found the best. It is more than likely that the above-mentioned plant will produce good seeds, so that many who are interested will again be able to possess this handsome blue Poppywort.

*Cucumis sativus* var. *sikkimensis*, a curious and interesting form of *Cucumber*, is fruiting in the Economic house. The most striking peculiarity is the network which covers the entire fruit much as in the Melon, and which renders it quite characteristic. It is commonly grown in all parts of the Sikkim and the Nepal Himalaya, where it is eaten both raw and cooked by the natives of all ages. It was found by Dr. Hooker in Sikkim in 1848, who brought drawings and specimens to England, and until then it had never been noticed either horticulturally or botanically. M. Naudin, who has made a special study of the *Cucurbitaceæ*, said when describing it that it was the most remarkable variety of the common *Cucumber* known to him. It is sometimes about 5 inches through, while only 1½ foot long. This, it may be mentioned, was the supposed hybrid between the *Cucumber* and the Melon, but the distinct species to which they belong have never yet been crossed. It was figured and described in the "Botanical Magazine" for January of this year, from specimens grown in the tropical economic house last summer.

*Calochortus citrinus* is flowering in the Orchid-house porch, where also have been several other species, as well as in one of

the herbaceous beds. This, which is the most recently figured, must be an excuse for calling attention to the decorative value of the genus, which includes also *Cyclobothra* as a sub-genus. Some are as brightly coloured as many of the very fugacious Irids, but have the advantage of lasting several days. It has recently been mentioned in a contemporary that they last a long time in water. They appear of easy cultivation, though likely to do best where, being planted in the open ground, they can have the protection of glass during very wet weather when at rest.

*Theropogon pallidus* is a newly introduced plant, figured in the "Botanical Magazine" last year. It has Lily-of-the-Valley-like flowers, with a pinkish tinge and a slight scent of something like cinnamon. The leaves are very narrow, with much the aspect of *Ophiopogon*. It is a native of the Himalaya Mountains, where it is a common plant.

*Kaiphofia caulescens* has been flowering in the herbaceous ground, and in the opinion of one authority is the finest of all. It is still very rare, from the fact that it will not divide like the other species. After attaining its arborescent habit the leaves and flower spikes lose a very considerable amount of vigour. If the development of its characteristic stem is thought most important, then the loss of handsome flowers and foliage must be borne. To produce the most ornamental effect it is necessary to keep the head low down, so as to be as near to the roots as possible, for the purpose of being well fed. It may safely be said that, like most of the Aloes, the top may be cut off and rooted without trouble. A safer method of procedure is to produce the roots before amputation, either by tying a bundle of damp moss round the stem, or by any other method that may suggest itself as best under the circumstances. A great advantage in taking off the top is that the old stump will give a stock of young plants.

## NOTES ON THE TWEED VINEYARD.

MANY of your readers will know that the principal crops of Grapes at this place are growing in five span-roofed houses, 200 feet long and 24 feet wide each. The crops in these this season are much superior to what they have been in previous years. All the Vines are now bearing to the extreme top of the rafters. The thinning, which employs half a score of men for twelve weeks every season, is just finished. The first thinned Grapes are nearly fully swelled. Of course it is quite out of the question to give a calculation of the number of the bunches, but the weight of many may be guessed pretty accurately. Lady Downe's, of which there are nearly two housefuls, are a magnificent crop. Few of the bunches can finish under 1 lb., and scores of them will approach 3 lbs. This is very fair for this variety. Alicantes are heavier in the bunch, and just about as abundant. Next to those two Gros Colman is perhaps grown most extensively amongst lates at present, and right well it looks; but Barbarossa will very soon be more plentiful than any other late variety excepting Lady Downe's.

At first the south house of the chief flock of vineries was wholly planted with Muscats. They succeeded very well, but it was found that they did not pay quite so well as Vines which produced black fruit. In the latter end of 1874 a young cane of the Barbarossa was inarched on to every Muscat stem. Last year the top part of the stock was cut away, and the growths which the Barbarossas made were of a first-class description; so strong indeed was the young wood that at pruning time from 6 to 8 feet of it was left to fruit this season. On many of these lengths there are now half a dozen bunches, and excellent clusters they are both in form and size. They will average from 4 lbs. to 7 lbs., and not a cane has missed a crop. The splendid crop they are carrying is not more worthy of note than the young wood they have made this season. That between the top of last year's wood and the top of the rafter on many of them is so thick that it can scarcely be spanned with the hand. There is another thing connected with these Vines worth mentioning—every top has the support of two roots. The young canes of Barbarossa, instead of being left in the pots when inarched, as is done in most cases, were turned out of the pots and planted about a foot from the Muscat root; the top is cut off the latter, and both stems join one another about 3 feet from the ground.

Amongst new Grapes Pearson's Golden Queen is promising well; Waltham Cross, a late white, has been tried every season since it was sent out, and it has as often completely failed. Mr. Douglas must be extremely unfortunate with the Duke of Buccleuch (see page 493). On scores of rods of it here this

season it has produced one and two bunches on every shoot. The crop of it now is one of the finest sights about the place, and the young wood is not far behind that of the Barbarossa. None of the hundreds of bunches will be much under 2 lbs., and the most of them will run between this and 3½ lbs., and the bunches and berries are as finely developed as any person need wish to see.

Pine-growing is all but given up. One of the Pine stoves 200 feet long is planted as a vinery. Muscats and the Duke of Buccleuch are the principal sorts. Another Pine stove 200 feet long is filled with young Vines in pots. Fruiting canes of the Duke and many other sorts were in fine condition here, as they were without exception in four or five other large houses, which are entirely devoted to growing young Vines. Excepting for early fruiting all the strongest Vines are grown into fruiting rods in one season, and judging from their size now they will be first-rate canes by the end of the season. Preparations are being made for erecting another vinery. It is to be a lean-to 250 feet long and 16 feet wide. Lady Downe's will form the principal stock here.

Plants are not largely grown; the only class of note being Orchids, and a more healthy or better grown collection is impossible to conceive. One splendid plant of *Lælia purpurata* had one fine spike of seven blooms of immense size and very rich in colour. All the Orchids here are grown in a much lower temperature than is generally the case, 40° at night throughout the winter being about the average, and right well the plants thrive with this. The finest plant of *Anthurium Scherzerianum* I have ever seen is here. It fills a 16-inch pot. The leaves are about 4 inches across, and the scarlet spathes are very large and bright in colour.

This is not intended as a full report of all that may be seen here of interest; but there is another thing which I must not forget to mention, and that is a new *Viola* which was raised here two years ago, and named Sir Walter Scott. It is very dwarf and compact in the habit of its growth. The flowers are of the most intense purple, and from 2½ to 3 inches in diameter. They are produced in dense masses, which are very effective. I had an opportunity of comparing it with others where all the best *Violas* are grown by the thousand, and every one of them were very much inferior to it.—A MIDLAND COUNTIES READER.

### UNIQUE PEA.

The desirability of a first dish of Peas is shown by the eagerness of the grower and the zest of the consumer. There is, of course, some difference of opinion as to the fitness of a first dish of Peas for gathering; also in having a heavy or light soil in equal climatic conditions to deal with in the production of early Peas. I remember well having a hard struggle to gather a first dish from a heavy clay by the time that Peas were had from the open fields in sandy soil, I having walls for shelter, and could if needed protect the crop. At that time there was no really good early dwarf Pea. The most that could be done was to sow on turves or in pots and plant out after the Peas had made so much headway as not to be longer continued in frames. Tom Thumb, and subsequently Little Gem, marked a new era in Peas, admirably adapted as they were from their dwarf growth and productiveness for warm situations, as the fronts of south walls, where the taller kinds could not be accommodated without injury to the fruit trees against the wall, and for frame culture and forcing. It is not now a matter of difficulty to command a dish of Peas at an early and late season. They force as readily as Kidney Beans, but require a lower temperature and more air. Where Potatoes and Strawberries succeed Peas may be forced successfully.

For forcing or for growing in cold frames (I find a span-roofed frame best for Peas and Kidney Beans to come in a month before those in the open ground), and for sowing a foot from the south wall, I consider Unique to be the best of the dwarf Peas. It is slightly more prolific than Little Gem, the pods are mostly produced in pairs, eight to ten on a stem, the pods slightly curved and pointed similar to Blue Scimitar, the peas, six to eight, being of a fine green colour. It is moderately robust in habit, attaining to a height of 18 inches. I sowed Unique this year on January 29th 1 foot from a wall with a south-west aspect, and had the first dish, a full even-sized crop, on the 28th of June. It is about 6 to 8 inches less in height than Blue Peter, and the crop ripens off very nearly together—a great point in a forcing Pea or one grown in a warm situation.

For the purposes named and for small gardens it is very desirable, alike for its earliness and good quality. I may say that William I. and First and Best, sown February 21st 3 feet from a south wall, are only just now (July 3rd) fit to gather.—A.

### ASTRANTIA MAJOR.

This was introduced from southern Europe many years ago, but is by no means a common plant. It belongs to a small but interesting genus, requiring no particular treatment in cultivation. Any ordinary garden soil will meet the requirements of these plants. They are the better if they are replenished now and again with a little good sandy loam until established, and then they will remain a long time without removal. When they have attained to a large size they may

Fig. 3.—*Astrantia major*.

be taken up, divided, and replanted, or reduced according to the operator's views. Being natives of mountainous districts they must not be allowed to suffer from too much moisture. They are quite at home in our borders and out-of-the-way places in wilderness scenery and partially shaded walks, where, if they can have light and air, they continue in bloom for a length of time.

*Astrantia caucasica* is of dwarf habit, and is a handsome plant on the shady part of the rockery. *A. pauciflora* is likewise of dwarf habit; it has pretty white flowers. It is, perhaps, the least known of the family, and is an acquisition to all collections. *A. carniolica* and *maxima* are taller and stronger-growing kinds. All are pretty, and deserve more extensive cultivation than they are at present receiving. *A. major* is an effective border plant, growing 2 feet or more in height; it commences flowering in June, continuing in beauty for a considerable time.—N.

### FEATHERED HELPS IN GARDENS.

I HAVE great pleasure in noting attention being drawn to the utility of peewits in gardens. We have been in the habit of securing some of the young birds for a number of seasons in May or June, and were formerly in the habit of pinioning them,

in which way we kept them for a number of seasons, but in times of hard weather—snow and continued frost—they perished from sheer starvation. These were “hard lines,” it being clear that we were guilty of their death, for had we taken measures only to stay their flight by clipping the feathers of one wing we might in severe weather have so cut the other as to permit of the birds escaping to find some food. In another way we were convinced of the cruelty of pinioning. A bird of this kind would escape by an open or unguarded door. A peewit escaping is certain to make clear off, and with its wing pinioned it has no chance of finding fresh pasture, or if it does its fate is sealed. It hurts the bird to pinion it; thus cruelty commences with its captivity and often is the precursor of its death. Just a last word—Place water for the birds to drink.—A. G.

## ALEXANDRA PALACE ROSE SHOW.

JULY 7TH AND 8TH.

BOTH for the high quality of the collections and the excellent effect they produced this Exhibition must take very high rank. It was the last of the metropolitan Rose shows, as it was undoubtedly the best. The Exhibition was held in the concert room, which is vastly superior to the large hall for such a purpose, the subdued light of the concert room showing the blooms to great advantage. The collections were arranged on four tables running the length of the room, the centres of which were occupied with Palms, Ferns, and Aroids, affording a pleasant relief to the formal and massive lines of Roses. Although many who had entered failed to stage their collections, yet the tables were very nearly filled, and the thousands of superior blooms afforded a rich feast of beauty to rosarians and the Rose-admiring public. The total length occupied by the boxes was about 1000 feet. The room was cool—agreeable to the visitors, and favourable for preserving the freshness of the blooms.

In the class for seventy-two varieties (nurserymen), the Judges after a long and careful examination awarded the first honours to Messrs. Paul & Son, Cheshunt. The blooms were full, compact and superior, and perfect in colour and freshness. Duchesse de Caylus, Duke of Wellington, Madame Lacharme, Felix Genero, Madame Clemence Joigneaux, Dupuy-Jamain, Marie Baumann, Richard Wallace, Victor Verdier, Madame Victor Verdier, Reynolds Hole, Annie Wood, and Paul Verdier were in superb condition. This is the finest collection of Roses that Messrs. Paul have this year exhibited; they have staged larger blooms, but never blooms of such uniform high quality. Mr. Cant, Colchester, was second with a very fine collection, most of the blooms being perfect, but a few were fully too much expanded. Most lovely was La Boule d'Or; and splendid were Emilie Hausburg, Horace Vernet, Fisher Holmes, Ville de Lyon, Prince Arthur, Charles Lefebvre, Madame Willermoz, Monsieur Noman, Black Prince, and Francois Michelin. Messrs. Cranston & Mayos were placed third. Bessie Johnson, Annie Laxton, Charles Rouillard, Sir G. Wolseley, Duchesse de Caylus, and Etienne Levet were very splendid; and Jean Cherpin, Fisher Holmes, and Reynolds Hole were a trio of dark Roses not easy to be superseded. Ferdinand de Lesseps and Madame Charles Wood were also exceedingly fine. Mr. Prince, Oxford, had the fourth prize. Le Havre, Devienne Lamy, Francois Courtin, Gloire de Santenay, and Henry Ledechaux were very superior; and the Teas, Madame Guillot, Narcisse, Marcellin Rhoda, Madame Jules Margottin, and Catherine Mermet were extremely effective. An extra prize was awarded to Mr. Keynes, Salisbury, for an admirable collection, the blooms being perfectly fresh and bright, but somewhat irregular as to size. The best bloom in the stand was Madame Marie Finger. The Teas, Souvenir de Paul Neron, Catherine Mermet, Madame Margottin, Souvenir d'Elise, Caroline Kuster, Madame Willermoz, and Jean Ducher were in superb condition. The Judges had a difficult task to perform in making their awards, and he would be a bold man to question the correctness of the decision of Mr. William Paul, Mr. Baker, and Mr. S. Hibberd. It is only such Judges who can deal satisfactorily with large collections so nearly alike in point of merit.

The next class, for forty-eight trebles, required also close and long examination before judgment could be delivered. The collections were exceedingly fine, the blooms equalling in quality those in the preceding class. Mr. Cant was declared the victor. In this collection Thomas Mills was simply grand; and splendid were Ferdinand de Lesseps, Etienne Levet, Marie Rady, Charles Lefebvre, Marie Baumann, Comtesse d'Oxford, Louis Van Houtte, Francois Michelin, Marguerite de St. Amand, Dupuy-Jamain, Baronne de Rothschild, and Devoniensis. Messrs. Paul & Son were placed second for a fresh and splendid collection. Louis Van Houtte, Monsieur Noman, Etienne Levet, Comtesse d'Oxford, Xavier Olibo, Annie Laxton, Senateur Vaisse, Exposition de Brie, Madame Therese Levet, Madame Vidot, Reynolds Hole, Mdle. E. Verdier, M. de St. Amand, Mad. Lacharme, and Maréchal Niel were perhaps as near perfection as these fine Roses have

been produced. Mr. Turner had the third place. Le Havre was here again in grand form, and almost equally splendid were Louis Van Houtte, Auguste Rigotard, Dean of Windsor, Royal Standard, Francois Lovat, Madame George Schwartz, Villaret de Joyeuse, Triomphe de Caen, Xavier Olibo, Lælia, Beauty of Waltham, Charles Rouillard, Marie Baumann, Etienne Levet, Fisher Holmes, and Alfred Colomb. Messrs. Cranston & Mayos were placed fourth for a collection containing many blooms of great merit, notably Annie Laxton, Marquise de Castellane, Madame Vidot, Mons. Noman, Princess Beatrice, Duchesse de Caylus, Fisher Holmes, La France, Madame George Schwartz, Madame Furtado, Louis Van Houtte, Ferdinand de Lesseps, and Madame Marie Finger; an extra prize being awarded to Mr. Keynes. In this collection Mdle. Marie Cointet was perfectly charming, and Fisher Holmes was grandly conspicuous; Camille Bernardin, Senateur Vaisse, Duchesse de Morny, Dr. Andry, Monsieur E. Y. Teas most beautiful, Francois Michelin, Edouard Morren, Ferdinand de Lesseps, Capt. Lamure, Etienne Levet, Madame Charles Wood, and Madame Marie Finger were all in full perfection.

In the class for twenty-four trebles six grand collections were staged, the prizes going to Mr. Turner, Messrs. Paul & Son, Mr. Keynes, Mr. Prince, and Mr. Cant in the order named. Etienne Levet, Francois Lovat, Le Havre, splendid; Madame Hazard, Marquise de Gibot, and Senateur Vaisse in the Slough collection were unsurpassable. The prize collections in this class contained the finest blooms to be found in the Exhibition.

For twenty-four single trusses the collections of Mr. Cant (first) and Mr. Turner (second) were nearly equal in point of merit, and far in advance of the others. Mr. Turner staged one of the finest blooms of Madame Vidot ever seen. Devienne Lamy, Alfred Colomb, Francois Michelin, Charles Rouillard, Duchesse de Morny, Marie Rady, Madame Charles Wood, Alba Rosea, and Devoniensis also showed to great advantage. The remaining prizes went to Mr. Keynes and Mr. House, Eastgate Nurseries, Peterborough.

For twelve Tea-scented or Noisette Roses Mr. Prince, Oxford, was first; Mr. Corp, Oxford, second; and Messrs. Paul & Son, Cheshunt, third. The best blooms in this class were Adam, Alba Rosea, Belle Lyonnaise, Comtesse Nadailac, Madame Willermoz, Marie Van Houtte, Marcellin Rhoda, Madame Opoix, Moiré, and Souvenir de Paul Neron.

We now come to the amateurs' classes, and find great competition and many highly superior collections. For forty-eight single blooms Mr. W. Nichol, gardener to T. H. Powell, Esq., Drinkstone Park, Bury St. Edmunds, was placed first with a collection of undeniable merit, and containing many blooms equal to the best in the Exhibition, notably Madame E. Verdier, Madame Lacharme, Mons. Noman, Marie Rady, Etienne Levet, Leopold I., and Annie Wood; second honours going to Sir C. R. Rowley, Bart., Tendring Hall, Colchester (Mr. Rushmore, gardener); Mr. Ingle, gardener to Mrs. Round, Birch Hall, Colchester, being third with very creditable collection; and Rev. J. B. M. Camm, Monkton Wyld, Charnmouth, fourth, Prince Arthur (dark) and Madame Trifle (white) being the best blooms, many of the others being fully too much expanded.

For thirty-six varieties, single trusses, the first prize went to T. H. Powell, Esq., for a really splendid collection. Maréchal Niel and Baroness Rothschild were very perfect, and nearly all the others good; the second place being occupied by Mrs. Round; third, Sir C. R. Rowley; and fourth, Rev. J. B. M. Camm. The first-prize collection reflected the greatest credit on the grower, the blooms being of “professional” quality.

For twenty-four Roses there were twelve competitors, first honours being awarded to Mr. Henry Atkinson, Brentwood, Essex, for an excellent collection; Mr. Smallbones, Chatteris, being second; Mr. Cavell, Oxford, third, the blooms being smoother and better than the Chatteris Roses; and Mr. Quennell, Brentwood, Essex, fourth.

In the class for twelve Roses there was great competition, twenty-two collections being staged—the finest lot of amateurs’ “twelves” we have ever seen exhibited. The first prize was awarded to Mr. Smallbones for Louis Van Houtte, Baroness de Rothschild, Maurice Bernardin, Edouard Morren, Comtesse de Chabillant, Alfred Colomb, Felix Genero, Camille Bernardin, Madame Rivers, Oliver Delhomme, Senateur Vaisse, and Francois Michelin; Rev. Alan Cheales, Brockham Vicarage, Reigate, being placed second, Charles Lefebvre and Leopold I. being very superior; Mr. Jowitt, Hereford, being third for smaller yet excellent blooms; and Mr. H. Atkinson fourth.

For twelve Tea-scented and Noisette Roses (amateurs) the first prize went to Mr. Ingle, gardener to Mrs. Round, and second to Mr. Camm, the first-prize collection only having three perfect blooms, while the second-prize box had at least half a dozen of superior quality. As a rule the standard of quality of the Tea Roses was not equal to that of the Hybrid Perpetuals.

In the open classes some very fine new Roses were exhibited. For twelve Roses of 1874, 1875, or 1876, Mr. Turner, Slough, was first with Villaret de Joyeux, Sir Garnet Wolseley, Miss Hassard, Isaac Wilkinson, Beauty of Slough, a splendid Rose and

sweet; Hippolyte-Jamain, Sir Salar Jung, very dark and very full; Royal Standard, Madame Liebhart, Jean Ducher, Rev. J. B. M. Camm, and Alexander Mackenzie. The last-named is after the style of Pitard, maroon suffused with violet. Every Rose here named was in splendid form, Isaac Wilkinson being perhaps the premier bloom in the entire Exhibition. Messrs. Paul & Son, Cheshunt, were second; The Shah, Sultan of Zanzibar, Duke of Connaught, Duchess of Edinburgh, Perle des Jardins, and Mons. E. Y. Teas being remarkably fine, especially the Rose last named, a variety likely to prove of sterling worth. The remaining prizes went to Mr. Keynes and Mr. Cant.

For six trusses of any Rose of 1874, 1875, or 1876, Mr. Corp, Oxford, was first with Hippolyte Jamain; Messrs. Cranston and Mayos being second with Sir Garnet Wolseley; Mr. Prince third with Mdle. Marie Cointet; and Messrs. Paul & Son fourth with Duke of Connaught.

For eighteen English-raised Roses in commerce Messrs. Paul and Son were placed first with, as the best, St. George, Bessie Johnson, Cheshunt Hybrid, Queen Victoria, Duke of Connaught, Peach Blossom, Beauty of Waltham, Princess Beatrice, Lord Macaulay, Devonensis, Empress of India, Princess Mary of Cambridge, Dr. Hooker, Reynolds Hole, Annie Laxton, and Duchess of Edinburgh. Mr. Turner being second with a collection little, if anything, inferior, comprising Mrs. Baker, Royal Standard, Sir G. Wolseley, Black Prince, Princess Beatrice, Peach Blossom, J. S. Mill, Miss Poole, Star of Waltham, Miss Hassard, Reynolds Hole, Devonensis, Marquis of Salisbury, John Hopper, Princess of Wales, Annie Laxton, Bessie Johnson, and Rev. J. B. M. Camm. Mr. Cant had the third prize.

For twelve Roses, distinct, Mr. Corp, Mr. Turner, and Mr. Tranter were placed in the order named. For twelve blooms of Edouard Morren Mr. House, Peterborough, was first for grand blooms; Messrs. Paul & Son being second. Mr. Cant was first for Princess Beatrice, and Mr. House second. For Madame Lacharme Mr. Cavell, Oxford, was first with the most perfect and lovely blooms which have perhaps ever been staged at any exhibition; Messrs. Paul & Son having the second place also with fine blooms. For twelve Maréchal Niel Mr. Cant had the first place with moderate blooms. For twelve Alfred Colomb Mr. Turner was first, and Messrs. Paul & Son second. For twelve La France first Mr. Cavell with magnificent blooms; second Sir C. R. Rowley. For twelve Marie Baumann first Mr. Turner, second Messrs. Paul & Son for admirable boxes; Mr. Turner's blooms having the best form, Messrs. Pauls' the best colour. For twelve Princess Beatrice first Mr. Cant, second Mr. House.

Roses in pots were not superior, Messrs. Paul & Son being the successful exhibitors. Neither were the vases of cut blooms of noteworthy merit; the prizes for these went to Mr. Rumsey, and Mr. Gardiner, gardener to Lady Garnier.

Mr. Rumsey, Joyning's Nursery, Waltham Cross, exhibited new Lobelias: *L. compacta Blue Perfection*, *L. compacta celestina*, and *L. compacta purpurea*, good and effective varieties; and Messrs. Dick Radclyffe & Co. tastefully arranged Fern cases.

As an exhibition of Roses this must be considered as one of the best and most effectively arranged that has ever been held in or near London. A quicker mode of placing the awards and the names of the winners is desirable. In this particular the Alexandra system is the slowest of all.

## SANDOWN PARK FLOWER AND FRUIT SHOW.

SANDOWN PARK is one of the most popular places of public resort, patronised by a large and influential class of society. Being situated at a convenient distance from the metropolis, and in a district remarkable for its salubrity and landscape beauty, it is a most enjoyable rendezvous apart from the many attractions which are provided for the enjoyment of its subscribers.

From the brow of the hill looking eastward the view is superb. To the right may be seen the glittering Palace of Sydenham, to the left the majestic towers of Windsor Castle, and in the foreground the severely massive and venerable palace of Hampton Court. The district, too, is richly wooded, so much so as almost to hide from view the Thames which meanders along the valley. The Park itself is also ornamental, the wood which crowns its highest point being fringed with beds of flowers. These beds are furnished, and the dressed enclosure is kept in excellent order by Mr. William Langstone, Milburne Nursery, Esher.

For the first time since the establishment of the Club horticulture has lent its charms to Sandown. The "gentle craft" was wisely considered to possess appropriate attractions for the "gentler sex," and an Exhibition was improvised under the superintendence of Mr. Wills of decorative fame. A comprehensive schedule was framed, and prizes amounting to nearly £400 were offered, and the days fixed for the display were the 7th and 8th inst. In this year of exhibitions it was no easy matter to find days for the show without clashing with other shows, and hence the fixture was unavoidably synchronous with

the Rose Show at the Alexandra Palace. Neither is the month of July the best time for a horticultural exhibition; the plants have then lost their glossy freshness, and the fruit is scarcely in its season of plenitude; but Roses are "in," and Roses were at Sandown, also plants and fruit. Considering, therefore, the season of the year, and also its being a first—an experimental—show, the result was very satisfactory and encouraging, and will probably lead to larger and more complete exhibitions in future years.

The products were arranged in three marquees, having communication with a lengthy corridor, and the tents and corridor were crowded with the competing collections; indeed, too crowded, and for "effect" too much divided. Had the whole been arranged in one large enclosure the Exhibition would have been much more imposing, but what was impossible this year may be accomplished on another occasion. On the second, the principal, day of the Show very heavy showers fell, which had a deterring effect on visitors, and the hoped-for arrival of the Prince and Princess of Wales did not take place.

A formal report of the Show is not called for. It was much like other shows in constitution and arrangement. In the nurserymen's class for nine fine-foliated plants Messrs. Jackson and Sons, Kingston; Mr. B. S. Williams, Holloway; and Mr. Ley, Croydon, were the successful exhibitors, staging very good collections. In the amateurs' class Mr. Bones, Oatlands Park, had the best specimens. *Croton interruptum*, a perfect plant, was 6 feet high, and the same in diameter at the base. He also staged other excellent specimens. Mr. King, gardener to R. Few, Esq., Wolsey Grange, Esher, was also successful. The same exhibitors, with Mr. Cornhill, gardener to J. S. Virtue, Esq., and Mr. Crafter, gardener to Rev. W. Finch, Kingston Hill, were successful with stove and greenhouse plants and Heaths.

In the Orchid classes the prizes went to Messrs. Rollisson and Sons, Tooting, and Messrs. Jackson & Sons. Messrs. Rollisson and Sons were first with *Dracænas*, and Mr. Ley with *Palms*. For exotic Ferns, which were very good, Mr. B. S. Williams, Mr. Cornhill, and Mr. Hinnell, gardener to S. Davis, Esq., Surbiton, were the successful exhibitors; and for hardy Ferns Messrs. Jackson and Mr. James, gardener to W. F. Watson, Esq., Redles. Mr. Baxindine, Guildford, exhibited good *Lycopodiums*, and remarkably fine *Caladiums* came from Mr. Foster, gardener to J. F. Lightfoot, Esq., Glenhurst, Ewell, and Mr. King. To both these collections first prizes were worthily awarded. Mr. Williams was the only exhibitor of *Agaves*, staging *A. Kerchovii*, *A. esiforme*, *A. americana*, *A. Taylorii*, *A. applanata*, and *A. Regeli latifolia*, a small but healthy and distinctly ornamental group.

Show and fancy *Pelargoniums* were extensively exhibited by Mr. Turner, Slough, and successful also were Mr. James and Mr. Croxford, gardener to Miss Dunnage, Surbiton. Amongst the newer show varieties from Mr. Turner, Lord of the Isles, Sappho, Prince Rupert, Toby, Despot, and Inflexible were highly superior. Zonal *Pelargoniums* quite 5 feet in diameter came from Mr. King; and very good variegated specimens from Mr. Morgan, Oak Lawn, Weybridge, and Mr. Tucker, gardener to A. Saunders, Esq., Woodbridge Park, Guildford. Collections of bedding plants, which were very effective and ornamental, came from Mr. Dean, Ealing, and Mr. Turner. Mr. Dean's had been grown in pans, and hence were awarded the first prize, Mr. Turner's having been recently potted from the open ground. Both collections were very good. Miscellaneous collections of plants were exhibited by Mr. B. S. Williams, Mr. Dean, Messrs. Rollisson & Sons, Mr. Bond, &c., and extra prizes were awarded.

Roses were very good. Mr. Turner was the principal winner amongst nurserymen, followed by Messrs. Vigo & Son, Guildford, and Mr. Fletcher, Ottershaw, Chertsey; and amongst amateurs the prizes went to Mr. James, Redles; Mr. Crafter, gardener to Rev. W. Finch, Woodlands, Kingston Hill; Mr. Moorman, gardener to the Misses Christy; and Mr. Ellis, gardener to J. Galsworthy, Esq., Coombe Leigh, Kingston. Mr. Turner exhibited a beautiful stand of *Carnations*, and also collections of *Verbenas*, which were greatly admired.

FRUIT.—Twenty Pine Apples were staged. Black Grapes were good, white Grapes poor. Melons, Peaches, Nectarines, and Strawberries were well represented. For three Pines Mr. Bond was placed first for capital Queens, which had been grown throughout the season without fire heat and without artificial bottom heat. Mr. Ward, Longford Castle, was second with Providence, and Mr. Childs, gardener to J. Gray, Esq., third. For a single Pine, any variety, Mr. Hepper, gardener to C. O. Ledward, Esq., was first with a capital Ripley Queen; Mr. Bond second, and Mr. Child third.

For baskets of black Grapes the prizes went in the following order—to Mr. Hinnell, Mr. Bond, and Mr. Taylor, gardener to Miss Taylor, Weybridge, each staging well-finished fruit. For a single dish of black Grapes the first prize was awarded to Mr. Edwards, Liphook; second to Mr. Hinnell, and third to Mr. Bridgeman, Marlow. For white Grapes Mr. Fillery, gardener

to Sir D. Sassoon; Mr. Edwards, gardener to W. B. Tristram, Esq.; and Mr. Kemp, were placed in the order named. — Peaches were very good; Mr. Sage, Ashridge Park, winning with highly coloured *Violette Hâtives*, followed by Mr. Strong, Woburn Park, Weybridge, and Mr. Kemp, gardener to R. Curtis, Esq., Kingston. In Nectarines Mr. Sage, Mr. Howard, gardener to J. Lovibond, Esq., Farnborough, and Mr. Kemp had the prizes; and for Cherries Mr. Strong, Mr. Sage, and Mr. Foster. Mr. Sage exhibited splendid Figs, and Mr. Lovibond remarkable fasciated Strawberries.

For a collection of twelve dishes of fruit in six distinct kinds Mr. R. Strong, gardener to W. J. Alt, Esq., Woburn Park, had the first place with Pines, Grapes, Peaches, Melons, Strawberries, and Raspberries; Mr. Kemp being second, and Mr. Cornhill third, each staging good collections.

Vegetables were very well exhibited. The best dish of Beans was *Seville Longpod*, and the best dish of Peas *Commander-in-chief*. For a collection of vegetables the prizes went to Mr. King, Wolsey Grange, Mr. Cornhill, and Mr. Croxford in the order named. The best brace of Cucumbers came from Mr. Langstone, who exhibited a new variety—*Empress of India*, a handsome very dark fruit having an intense bloom.

The Exhibition was well managed, the best attention being paid to plants and visitors by Mr. Dean.

### THE REIGATE ROSE SHOW.

THE Reigate Association for the cultivation of Roses held its tenth annual meeting in the grounds of A. J. Waterlow, Esq. It had been postponed from the 24th ult. because of the lateness of the season, and an excellent Show justified that generally undesirable proceeding. Under the fostering care of its two presidents—Mr. Wilson Saunders, F.R.S., of world-wide floral fame, and now Mr. Baker—the Reigate Association has been gradually educating its members into an advanced stage of Rose-growing, so that, as has been lately seen in the great London contests, its members can encounter with success the first amateurs in England. At present this Association keeps all its good things for itself, unlike its once foster child the Maidstone Association, which collecting the trade and amateurs from all parts of the kingdom, has gained the glory of having this year the best show of the season.

Reigate has no strangers' prizes; the chief interest of her Show centres in three challenge cups—the ladies' cup for the best twelve Roses, to which is annexed the onerous task of winning it at three consecutive shows; the cup for the best twenty-four, and that for twelve Teas, which latter will be taken whenever they have been won three times by the same individual. Mr. Sargent having won the twenty-four cup twice, and being fresh from the scenes of his victories at the Westminster Aquarium, great interest and expectation were excited by his competition. But the glories of the day were with the house of Waterlow; in every class its Roses were unapproached. Two cups were assigned to them, the third, or ladies' cup, being won for the second time by Captain Christy. The members are to be congratulated on the excellence of the Show. The twenty-fours were pronounced by the Judges of a high excellence, and such as would have held their own in any competition. The bouquets and devices were also many in number and much to be admired.

The Judges were Mr. George Paul of Cheshunt, Mr. Francis of Hereford, and Mr. Mitchell of Uckfield.

### TUNBRIDGE WELLS FLOWER SHOW.

JULY 7TH.

Few places can present greater attractions for visitors from London than Tunbridge Wells with its numerous villas and pleasant drives, and there is scarcely any district near London where so much attention is paid to the villa gardens, with their lawns and evergreens and shady walks; but an additional attraction was held out on Friday the 7th, when the annual Show of the Tunbridge Wells Horticultural Society was held in the great Hall and grounds immediately contiguous. The Show has now gone on and prospered till it is second to few country shows, and it is particularly noted for the amount of support that it receives from local gardeners and amateurs; indeed few societies can muster so many good competitors within a limited area.

We entered first into the Hall arranged with six sets of tables, two of which were devoted to Roses, two to table decorations, bouquets, &c., and two to fruits.

We will begin our observations, as in duty bound at this time of the year, to the queen of flowers. Two classes, one of forty-eight trebles and another of twenty-four trebles, were devoted to the nurserymen. In Class 1 (forty-eight trebles) Mr. Mitchell, Piltown Nurseries, was first. Amongst his were some very fine examples of *Marie Rady*, *Marie Baumann*, always beautiful for form; *Henri Ledechaux*, fuller and larger than it is usually exhibited; *Joséphine Malton*, *Baroness Rothschild*, exhibited in

great perfection in many stands; *Madame C. Joigneaux*, *Monsieur Noman*, &c. There was also a promising seedling of the type of *Senateur Vaisse*, and a sport from *Clemence Joigneaux*, almost the colour of *Capitaine Christy*. The second prize fell to Messrs. Bunyard & Son of Ashford—a good collection, well set up, but not so large or fine as Messrs. Mitchell's. Amongst others they had very good *Maréchal Niel*, *Mlle. Eugénie Verdier*, *Fisher Holmes*, *Baroness Rothschild*, and *Madame Willermoz*. Mr. Piper of Uckfield was third with smaller compact blooms, amongst which were good specimens of *Jean Rosencrantz*, *Jean Chérpin*, and *Miss Ingram*. There were four other collections.

In twenty-four trebles there was a very close competition for the first prize between Mr. Piper and Mr. Knight, and Mr. Bunyard was a very good third. We need not particularise Roses in these stands, except to name two very beautiful blooms of *Louis Van Houtte* in Mr. Knight's stand. *Miss Ingram*, *La Fontaine*, *Comte de Paris*, and *Madame M. Rady* were also well exhibited in Mr. Piper's stand. There were four classes for amateurs and gentlemen's gardeners, and rarely have we seen closer or better competition than in Class 17 for twenty-fours and 18 for twelves.

In Class 17 there were seventeen entries, and three extra prizes were awarded besides the first four which were allotted. Mr. A. Gibson exhibited a very fine collection, which would have done credit to any show both for colour, size, and quality. Amongst others a most perfect *Dupuy-Jamain*, very good *La France*, *Marie Rady*, *Maréchal Vaillant*, and *Duke of Edinburgh*. The second, third, and fourth were but little inferior. In the second were very good specimens of *Etienne Levet*, *Dupuy-Jamain*, and *Baroness Rothschild*.

Class 18 had twenty-three competitors, and here again the competition was very close; but the twelve shown by Mr. H. Bensted were most uniformly good, indeed we have rarely seen a better twelve; amongst them *M. Lacharme*, a bloom which would have rejoiced the heart of "D." of Deal; *Maréchal Niel*, very good; *Charles Lefebvre*, the best in the room of its kind; *Reynolds Hole*, with more petal and substance, and more nearly approaching his or her synonym (by the way, the genus *Rosa* is feminine; how about those Roses, as *Reynolds Hole*, *Charles Turner*, *Rev. J. B. Camm*, *Rev. H. H. Dombrain*, &c. ?); *Alfred Colomb*, *Xavier Olibo*, and *Camille Bernardin*. The worst Rose in the lot was *Capitaine Christy*, and if we mistake not it will not long enjoy high honours as an exhibition Rose. It is apt to open flat and to discolour. Mr. Ridout, who had the second prize for twelve singles, had some very good specimens of *Camille Bernardin*, *Reynolds Hole*, *Exposition de Brie*, unusually good; *Marie Baumann*, and *Pierre Notting*.

Class 19, twelve Teas and *Noisettes*, had nine entries, and there was a much better and closer competition for them than usual; but somehow or other, beautiful and sweet as Teas and *Noisettes* are, they never make a really good show when set up together, and yet unless exceptionally good they very often let down a stand of Hybrid Perpetuals. The best Teas exhibited were *Souvenir d'un Ami*, *Maréchal Niel*, *Souvenir d'Elise*, *Cheshunt Hybrid*—but query, is not this a cross between a Tea and Bourbon with but little Teascent? There is some confusion between Teas, *Noisettes*, and Bourbons. For instance, some call *Maréchal Niel* a Tea, whereas it is a Tea-scented *Noisette*; and *Gloire de Dijon* a Tea when it is more than four parts Bourbon. *Gloire de Bordeaux* again, *Madame Levet*, *Louise de Savoie* are much nearer Bourbons than Teas.

Class 20, a level class, twelve single blooms, not less than four had some good Roses; but we think it would be better to make it six or eight singles, separate varieties, or at once four trebles, as it is rather confusing some with four, some five, six, seven, eight, nine, &c., varieties.

So much for the Roses, which does not leave us much space for the other exhibits. There were very good collections of table decorations, though with the exception of two, one of Poppies, white Dog Daisies, and dark purple-leaved Beech; and another a single vase with yellow *Eurothera* and purple-leaved Beech, evidently by the same exhibitor, there was nothing new or different from what we generally see exhibited; still the first prize both for three pieces for table decoration and for one piece, and the second prizes were good. We could almost wish we could get rid of the stereotyped Grasses, blue Cornflowers, &c.

There was a very large entry for vases of wild flowers, and as a rule exceedingly good. We could have wished the one with white Water Lilies had been noticed by the Judges. We counted forty-seven entries for pairs of button-hole bouquets, but the quantity was greater than the quality.

We must not stop to particularise the Fruit, but the competition for Grapes was good, and also for Melons, and there were some very fine Peaches and Strawberries, Sir J. Paxton as usual to the fore.

There were three tents for the plants. Mr. Ward, gardener to F. Wilkins, Esq., Leyton, was *facile princeps* in stove and greenhouse plants, and unless we are mistaken in everything he exhibited, his eight stove and greenhouse comprised three very good *Ericas*, *Stephanotis*, *Bougainvillea glabra*, very evenly bloomed; *Clerodendron Balfourii* as usual very

good; *Anthurium Scherzerianum*, and *Ixora javanica* var. *floribunda*. He was the only exhibitor for six stove and greenhouse plants, and also for the *Ericas*, but they would not have been excelled easily. We must also notice a single specimen of *Anthurium Scherzerianum* variety *Wardii*, with six of the finest spikes we have ever yet seen, the spathes from 6 to 7 inches long and 4 wide.

In the same tent were very good *Caladiums* and foliaged *Begonias*, very fine *Selaginellas*, the first six being grown in a pyramidal shape, and far more effective than the usual flat pans so often exhibited. The zonal *Geraniums* were not particularly good. The first-prize plants were large and the blooms fine, and the plants not too much tied out. The *Fuchsias* as a rule were good, and also the *Ferns*, especially the first and second-prize collections.

In another tent were staged zonal *Tricolors* and *Bicolors*, fancy and large *Pelargoniums*, and *Coleuses*. There were four very good collections of six *Coleuses*, the first-prize having a very fine *Duchess of Edinburgh* and good specimens of *Beauty of Widmore*, *Roi Leopold*, *Her Majesty*, *Princess Royal*, and *Princess Beatrice*. The *Pelargoniums* do not call for much comment, though in the second-prize group were some very fair seedlings. The *Tricolors* and *Bicolors* were both badly coloured, and the fancy *Pelargoniums* only moderate. In this tent were two miscellaneous collections attractively arranged.

In a third tent were the cottagers' exhibits, and which, especially for fruit and vegetables, were most creditable to the district. One dish of Sir Joseph Paxton Strawberries were scarcely equalled, certainly not surpassed among the amateurs; and the kidney and round Potatoes were very good and fine for this late season—far more fit for exhibition than we should have expected. The Cabbages, perhaps, were somewhat large, but what would have disqualified them if shown by a professional gardener is certainly a fault on the right side in cottage-garden collections.

Our remarks have run to a great length, but we may conclude that with a fine day, a good show, and a goodly muster of the ladies and gentlemen of the neighbourhood, we have all the elements of a successful exhibition, which this one we are now chronicling decidedly was.

### ROSES FROM CUTTINGS.

As there seems to be some uncertainty as to which of the Perpetual Hybrid Roses may successfully be propagated by cuttings for outdoor growth, I subjoin the names of some in my possession, in the hope that an expert will tell us which of them it is undesirable to attempt to propagate in the above way. I take it for granted that all Teas, Bourbons, Chinas, and hybrids of these may be used.

Alfred Colomb, Antoine Ducher, Annie Wood, \*Baronne Prevost, \*Boule de Neige, Charles Lefebvre, Charles Turner, \*Dr. Andry, Duc de Rohan, \*Duke of Edinburgh, \*Edouard Morren, \*Elie Morel, Ferdinand de Lesseps, \*Général Jacqueminot, \*John Hopper, La France, Ville de St. Denis, Le Rhone, Louis Van Houtte, \*Madame Lacharme, \*Madame Victor Verdier, Madame W. Paul, Mdlle. Bonnaire, Mdlle. Eugénie Verdier, Marie Rady, \*Marguerite de St. Amand, \*Marquise de Castellane, \*Mons. Woolfield, \*Prince Camille de Rohan, Senateur Vaisse, Star of Waltham, Abel Grand, Marie Baumann.—A. J.

[Nearly all the varieties named in your list will strike from cuttings; those marked with an asterisk (\*) we know will do so most readily. Any Roses will strike root by the simple process of layering or tonguing the shoots. Forty years ago our Roses were all propagated in this way, and now, perhaps, for amateurs the most certain way for procuring Roses on their own roots is to obtain in November bushy plants of any Perpetual on the Manetti or other rootstocks, tongue or pare-up a little strip of bark about an inch long with an eye in it near the base of each shoot, then plant the tree in a trench as for Celery and earth-up over the tongued parts. You can take the parent plants up in the following autumn, when each tongued part will have a growth of roots. Split these off and replant.]

### CASTLE COCH VINEYARD.

HAVING had a look through the experimental vineyard at Castle Coch, I think a note of the present appearance of the Vines may be acceptable to the readers of the Journal.

The growth of the Vines is clean and extremely healthy: not a single leaf is to be seen affected by the cold month of May which we experienced in this county, which is saying a good deal for the naturally fine situation of the spot selected.

The majority of the canes are to the top of the stakes, and some (July 5th) are being stopped at a foot above it. In the

whole (nearly three thousand) I could not detect any failures; and from the present forward appearance of the canes there is good prospect of their ripening well, on which certainly success depends. The damp winters experienced along this side of the British Channel being quite a secondary consideration, the natural drainage being perfect and the loam unexceptionable to the full depth moved—viz., 3 feet.

Of course there is the contingency of wet autumns preventing the ripening of Grapes; but all interested in horticultural experiments will wish the trial success.—R. C.

### EXHIBITORS' WRONGS.

WE think some recent proceedings are specially worthy of notice, to show the difficulties exhibitors labour under, and we hope some standard rules may be suggested for the guidance of judges and for rendering schedules more explicit. At the Aquarium several pretty epergnes were disqualified because they were not "vases." Turning to Johnson's Dictionary, we find "Vase, a vessel generally for ornament." Would this not apply to an epergne, or did the Judge expect a garden ornament, and in revenge awarded the first prize to a flower pot as coming nearer the views of a vase? 2nd, A table decoration was disqualified, but highly commended, because it would be more appropriate for a larger table; yet they overlook the fact the schedule specifies a table completely laid in every particular for fourteen persons, and they allot a space scarcely large enough for ten at most. At the Botanic Society a table which proved so attractive visitors had difficulty in getting near to it, and which was purchased by a visitor, was disqualified on some grounds, although prizes were awarded to tables, or rather decorations, which if on a table fully equipped would have been even more crowded than the fully appointed and disqualified table.

Another cause of complaint is withholding prizes because there is but one entry. If this is fair, would it not be reasonable to expect the Secretary, who knows at least three days beforehand, to inform the intending exhibitor and save him the expense? To say the least, it is hardly likely to stimulate the trade to contribute to the shows, and insure the great success they require to keep the Societies in funds.—DICK RADCLIFFE & Co.

### MR. JOHN PEARSON'S NURSERIES, CHILWELL.

I HAD long been desirous of visiting Mr. Pearson, having read many years ago of his orchard houses being famous for producing large crops of Peaches and Nectarines on the bush or pyramid system. But orchard-house culture is not the special feature at these nurseries now; the trees are grown to sell as well as to produce fruit, and very clean and healthy the trees are, although a large number of specimens have been disposed of this and last season. Mr. Pearson's fruit trees are always kept under glass, and no doubt this is the best way in cold wet districts; but we find in the neighbourhood of London that it is not essential to the health of the trees to keep them in the house all the winter. We have a large number of fruiting trees at Loxford, and all of them have been turned out of doors in the winter for the last ten years, and when they are taken in from the plunging material in January or February, it is found that the roots are in an active state, growing quite freely.

The soil at Chilwell seems well adapted for the culture of these trees. I noticed the "maidens" that had been potted-up to produce fruiting trees for next year were very strong, and they were making splendid growths. These two-year-old trees will sometimes produce very fine fruit. I potted a "maiden" Pine Apple Nectarine in a 10-inch pot once, and pinched in the growths twice during the season, and the year following I gathered from that two-year-old tree six Nectarines which gained a first prize at one of the London exhibitions, and they were very much admired. The tree of course was carefully tended, but all first-prize fruit must be well cared for, whether it is grown on large or small trees; and such trees as are grown at Chilwell will surely produce fruit next season.

There is one thing greatly in Mr. Pearson's favour, and that is the quality of the glass houses. There are a dozen or more large span-roofs, and as many of a smaller size adapted for *Pelargoniums*; and they are built to last, not tumble-down sheds that would not last a decade, but they are such as would stand for fifty years, and the workmanship is a credit to any builder. There are also some improvements in their con-

struction worthy of being universally adopted. One of these is in the system of glazing. The glass, instead of being cut in a straight line, is rounded like a cheese-cutter or the blade of a turfing iron; this causes the rain to run down at the middle of the glass panes, and quite prevents the water from soaking down between the glass and sashbars. The under sides of the bars are also constructed with a runnel from the top to the bottom of the house, and all condensed water is carried down this runnel to the wall-plate, so that there is no drip either from condensation or rain. The top ventilator is moved by machinery, which is worked by a wheel and axle outside the houses. A man can move the whole top ventilation of a house 100 feet long with apparent ease, and the apparatus when opened to its fullest extent prevents any rain from reaching the plants underneath. The ventilation and glazing adopted by Mr. Pearson is as perfect as any that I have ever seen.

There are some very good Grapes of the old-established sorts grown, but the houses are not specially intended for Vines, as many other plants are grown in them for the greater part of the year. In a lean-to house are the famous seedling Vines which Mr. Pearson has raised by crossing with the American varieties. Here are the original canes of Mrs. Pearson, Golden Queen, and the Chilwell Alicante. If I remember rightly Mr. Pearson received a prize, given through the Royal Horticultural Society, for Golden Queen, as the best new fruit of that year. It is one of the richest-flavoured white or golden-coloured Grapes that has yet been raised; the bunches are large and shouldered, and the berries large. Mrs. Pearson is a distinct-flavoured white Grape which I have not yet tasted, but it is said to be superior even to Golden Queen. Besides the above there were raised, previous to this, Dr. Hogg and Ferdinand de Lesseps. The first-named is the best Frontignan, round-berried white Grape; the bunches and berries are much larger than the old White Frontignan, or Chasselas Musqué. Ferdinand de Lesseps was raised by crossing the Strawberry Grape by some of our English varieties. It is Strawberry-scented, and a delicious-flavoured golden-coloured Grape.

The pot Vines were in excellent health, including a large quantity of Golden Queen and Mrs. Pearson. The Black Muscat of Alexandria (Muscat Hamburg), is worked upon the Frankenthal or Hamburg stock; but I think if Mr. Pearson has opportunity he should try it upon the Muscat of Alexandria. Mr. Pearson had something to show by way of experiment in one of his houses of young Vines. One particularly healthy Vine making most vigorous growth was pointed out as one that had fifty-three wireworms in the soil. This was done to prove that this pest does not injure the roots of Vines; and most conclusively has it done so, for the plant was turned out of the pot a few days after my visit, and the greater number of the wireworms were alive and well; but they had not grown fat on the Vine roots. Many gardeners in Britain will be glad of this conclusive experiment, and will not spend their time in hunting for a few wireworms that may be in the turf used to make their Vine borders. The Vine borders at Loxford Hall were made almost entirely of turf that contains quantities of wireworm, but they were not picked out, and the Vines have flourished from the day they were planted until now, producing annually many first-prize Grapes and healthy clean foliage. On the other hand, the wireworm is an intolerable pest to the Carnations, and many fine plants are destroyed by it annually, although all the soil is picked over two or three times before using it.

One of the greatest attractions at Chilwell at present are the seedling Zonal Pelargoniums. There are many hundreds flowering this year for the first time, and hundreds more that have been marked and are now being rapidly propagated to be sent out. One of the best, and it has been out some years, is Corsair. I have not yet seen it planted-out in beds, but it would certainly be a good bedder from what I have seen of it in a mass. I noted Mrs. Walter as being a very fine variety with golden tricoloured leaves; the light crimson zone and yellow margin was very striking. Lady Sheffield is a plain-leaved sort with bright rose-coloured flowers. H. S. Stanhope, very dark crimson; Mrs. Walker, crimson; and Livingston, deep rich scarlet; Colonel Seely is a very bright scarlet. All the above are distinct, the habits of the plants good, and the trusses large and held-up on stout stalks. Many of what Mr. Pearson thinks his best flowers were not out at the time of my visit. Some other good varieties have been recently noticed by Mr. Muir.

There is also a very large span-roofed conservatory which contains a fine lot of healthy plants, the most useful amongst

them being the Azaleas, of which there is a superior collection. I made a few notes of some of the best and most useful for decorative purposes. Charmer is a very good sort, with large well-shaped rosy purple flowers. Eclatante has deep crimson flowers shaded with dense purplish crimson. Mdle. Marie Lefebvre, fine white. Mdle. Marie Van Houtte, white with rose stripes, is a fine sort. Comtesse de Beaufort, pale rose, upper part of the petal crimson. Mdle. Leonie Van Houtte, very pure white with rose marking. Due de Nassau, a good old sort with rosy purple flowers.

A large number of early-flowering Pelargoniums of the large-flowered or show section are grown for cut flowers early in the year, and well adapted they are for this purpose. Bridal Bouquet is one that should be grown everywhere; the plants were covered with a profusion of pure white flowers with a delicate rose blotch on the upper petals. Digby Grand is also a fine free-flowering variety; the flowers are fringed pure white, with a dark blotch on the upper petals. Like the rest of the productions at Chilwell, all the plants in this house are clean and well cultivated.

I ought not to omit noticing two immense Rose bushes which were growing in the orchard house. One is Lamarque, and under glass the flowers were white, though they may be described as pale straw when grown out of doors; they were produced in great abundance and of fine quality. The other was a grand plant of Maréchal Niel, which produces annually between two thousand and three thousand flowers. These two are the best Noisette Roses, and should be grown wherever space can be had under glass. They should be planted out.

Mr. Pearson has a well-kept lawn adjoining his house, on which there are some handsome coniferous trees, Pinus macrocarpa and Cupressus Lawsoniana being large and very perfect; and here the new bedding Pelargoniums are tested in small beds cut out of the turf before they are recommended to the public.

I cannot conclude this short notice without giving a meed of praise to a younger son of Mr. Pearson, who has had a considerable part of the management during his father's illness, and who seems quite as great an enthusiast as Mr. Pearson both in plant and fruit culture, and I must also thank him for the great pains he took to show me everything in the construction of the houses and the culture of the plants and fruit trees.—J. DOUGLAS.

## ASPECTS OF NATURE.—JUNE.

"The mead is our study, and Nature our book."

WHATEVER may have been the character of the weather during the earlier months of the year, June generally brings us a time of full summer, a season when we may take extended rambles in the country and still enjoy "the long sunny lapse of a summer day's light," for our return when wandering in woods and lanes, rambles on moor or in meadow, will give us the largest bouquet of wild flowers that it is possible to gather during any time of the year; indeed, so many lovely blossoms are around us, that the great difficulty is to know which to choose for emblems of Flora's garland for the month; but as the Rose has been chosen queen of the parterre so will we make her first among wild flowers of June. The Briar is in the resplendence of her beauty, and hangs her pliant blossom-decked sprays over every hedge, or twines around the Oak sapling in the copse, and in companionship with the Honeysuckle or Eglantine hangs graceful festoons of foliage and flowers across many an unfrequented path. To the uninitiated all wild Roses are alike; but those who have gathered them with affection and sought them in different habitats have learnt to distinguish several varieties, from the deep rich petals of the darkest, down through all the shades of pink to pure white. Nor are the foliage and growth of all similar, for beyond those which have lighter or darker green leaves, more robust or more pliant stems and branches, the beautiful sand Rose is distinct in all its features, growing as it does on low sandy hills, exposed to the bleak winds which blow from the ocean. Its natural growth is that which best befits a plant that has to bear the beating of many storms. The finest specimen is indeed but a low shrub thickly set with branches rising almost from the base, the leaves being of a deep rich brown, much serrated and very small, the beautiful pure white flowers being strongly scented. Every stem is clothed with fine but numberless spines, as thick as those on a Moss Rose, and it is these, doubtless, which protect the hearts of the plant from being choked up during its early growth by the thick clouds of sand

which every wind blows over it. On one particular part of the Cheshire coast, between the mouth of the Dee and that of the Mersey, close to the rocks so well known as the Red Noses, the sand hills which skirt the shore are, or were a few years since, covered with these fragrant Rose bushes, and where a little soil had mixed with the sand the wild Thyme and the close-growing Miller's Thumb made a carpet of purple and gold beneath them. On the opposite shore of the Mersey a low, level, and somewhat marshy plain stretches for miles along the coast, and here, just protected from wind and wave by the continuous heaps of sand which accumulate about the Arundo or Bent Grass, so plentifully growing in the neighbourhood, are rich stores of wild flowers too numerous to name. Among them the wild Mint is so abundant that its scent is inhaled with every breeze, and every footstep crushes out a richer fragrance. Here also grows the beautiful Grass of Parnassus with its solitary ivory cup, so exquisitely veined, so purely white.

Beautiful as are the woods at this season, they are excelled in floral splendour by the banks of streams and the edges of marshy meadows. Such spots are gorgeous with bloom, and set with an enamel where all shades of colour blend or contrast to form a harmonious whole. Great patches of Forget-me-not still clothe the river's brink and stretch their lovely blossoms towards the stream; while growing beside them in many places, and pushing its tender green shoots clothed with bright yellow flowers, is the Moneywort, the Creeping Jenny of the London markets. Both plants love moisture, and grow to perfection on moist banks beneath the shadow and protection of bramble and thorn. Not only the sides of the streams, but the water itself is rich with beauty, for

"The Lilies have spread their bells  
O'er all the pools in the forest dells."

And not only there, for the ponds and streams of open meadows and park have gathered to their bosoms the broad floating leaves and brilliant cups of the Lotus and yellow Water Lily. The elegant tall reeds and numerous aquatic plants are now coming to perfection, and fringe the streams with graceful foliage, Narcissus-like admiring their own reflections in the limpid water. Along the hedges of low-lying lands, by river or streamside especially, the beautiful wild Guelder Rose is now in full bloom; and though the flower is not so large nor double as that of the garden variety, it is quite as interesting with its outer crown of cruciform florets around the lesser florets that form the centre.

The forest trees are now all arrayed in the fulness of their foliage, realising Spencer's description—

"Then came jolly Summer, being dight  
In a thin silken cascock colour'd Greene,  
That was unylned all to be more light;  
And on his head a girland well besene  
He wore."

June is the month above all others of sweet scents, when the air is loaded not only with the rich perfume of new-mown hay, but the delicate odours of Honeysuckle are wafted on the breeze, and the Beans now in full blossom exhale the perfume of honey so strongly that it is but natural to find their myriad blossoms being rifled of their nectar by the ever-busy bee. The Bean fields in flower inspired one of the happiest chapters in Alphonse Karr's "Voyage Autour de Mon Jardin."

At the beginning of the month the Grasses in the meadows bend their heads to each passing breeze, reflecting in waves of light or shade every gleam of sun and every flying cloud.

After extreme heat how delightful is the change to rain, when the parched earth sends forth her rich moist smell, as though diffusing a natural incense in gratitude for timely showers! The advent of rain in summer is thus exquisitely described by Thomson:—

"Gradual sinks the breeze  
Into a perfect calm, that not a breath  
Is heard to quiver through the closing woods,  
Or rustling turn the many-twinkling leaves  
Of Aspen tall.

At last  
The clouds consign their treasures to the fields,  
And softly shaking on the dimpled pool  
Prelusive drops, let all their moisture fall  
In large effusion o'er the freshen'd world."

But it is not alone that the hedgerows and meadows are gay with flowers—that the graceful wild Bryony and beautiful Belladonna appear about the hedges, that fields are enamelled with Flora's wildlings of every hue. Insect life is this month in its strength and beauty. Glow-worms show their

tiny lamps in the damp moss, and may at eventide be supposed to light

"Those fairy elves  
Whose midnight revels by a forest side,  
Or fountain, some belated peasant sees—  
Or dreams he sees; while overhead the moon  
Sits arbitress, and nearer to the earth  
Wheels her pale course."

The field crickets also chirp their evensong during the month of June, when the hum of busy human life is stilled, and "the toilworn coter fra his labour goes" to rest awhile and enjoy the cool shades of evening at his cottage door. As the season advances and the insects increase in numbers, as the beetles of all the bright and varied tints of the rainbow may be seen gemming the ground at eventide, or resting during the heat of the day under the leaves on some sunny bank, or hiding in the petals of a Rose; as the chirrupings and drowsy hummings of the insect tribes increase, the songs of the birds are hushed; and as the month declines the lonely whistle of the stone curlew is heard at night, and during the day the occasional pipings of the goldfinch, yellowhammer, and golden-crested wren.

"The groves, the fields, the meadows now no more  
With melody resound. 'Tis silence all,  
As if the lovely songsters, overwhelmed  
By bounteous Nature's plenty, lay entranc'd  
In drowsy lethargy."

—T. S. J.

## EATON HALL,

THE SEAT OF HIS GRACE THE DUKE OF WESTMINSTER.

UNLIKE Chatsworth or Trentham, Eaton Hall owes but little to the beauty of its situation or the grandeur of its surroundings. The princely seat of the Dukes of Devonshire stands so grandly amidst its wooded hills; and the hardly less beautiful seat of the Dukes of Sutherland by the side of the shining Trent is so exquisitely rich and lovely, that the magnificence of the residence seems to be lost in the beauty of the setting. Few places could compare with them in these respects, and most certainly not Eaton. It is true indeed that there are lovely views to be obtained from it, as when standing on the front terrace the eye rests on the old ruins of Beeston Castle, which all travellers by the London and North-Western line must remember; or from the back of the house a distant view of the Welsh hills is obtained; while ever and anon the glistening of the Dee appears through the foliage like a silver thread, adding, as water ever does, so much charm. But withal Eaton is inferior in natural beauty, I think, to the other two: or is it that one has seen the others first and the charm of their beauty has made one fastidious? It may be so.

The Hall itself is undergoing a complete transformation, the taste of the present owner not being satisfied with the florid Gothic of Edward III.'s times. Indeed it has been altered and rebuilt several times. A brick mansion from the design of Sir John Vanburgh stood upon the present site; this was taken down in 1803, and a magnificent building from designs by Porden, combining Gothic with some details of the Tudor architecture, was erected on its site. This is now giving way to what will be when completed a magnificent specimen of the Renaissance style, one of all others best suited for elaboration of detail and for general convenience and comfort. At present scaffolding and an army of masons and sculptors have possession of the building, but amidst their confusion some idea of the future beauty of the building may be obtained; and when one recollects that in the course of some years the estimated income of the dukedom of Westminster will be a million of money, it will be readily understood that nothing will stand in the way of its being made worthy of the noble name of Grosvenor.

But neither my tastes nor the interests of the Journal draw me much towards architecture. I have to tell of its gardening and surroundings; and it will be readily conceived that under the care of Mr. Selwood, a favourite pupil of Mr. Stevens of Trentham, there is little lacking here, where a liberal and generous-hearted employer is ever ready to second the efforts of all who serve him. Hence in whatever department of the garden one looked there was evidence of care and skill. Instead of entering into minute descriptions of the houses, their position and contents, I shall rather indicate those points which most struck me as noteworthy—for in all these large places there must of necessity be similarity in many respects, the points of difference being really the points of interest—

leaving aside the size of the houses, their number and situation, as matters which may readily be imagined.

The soil of the garden and the park generally is red sandstone, and is found to answer well for Figs, Peaches, Roses, and Melons, and of this there was abundant evidence as we went through. There is one remarkable Fig pit, which was planted thirty years ago, and which produces an enormous quantity of Figs every year. The plants never grow above 3 or 4 inches annually, but nothing could be better than their appearance, and it struck one as a most convenient way of growing this luscious fruit, the excellence of which we are beginning to appreciate. The pit is a plain one, such as is used for Melons and Cucumbers, although of course considerably sunk. The trees are planted closely in it, so that one sees only a dense mass of foliage. Melons were grown as well as Cucumbers in houses, and the crop of the former was something remarkable; the variety grown being Colston Basset, of

which Mr. Selwood speaks highly, and another (as is usual in these large places) a favourite one originated in the place, and a sight more suggestive of good culture and favourable conditions than the Melon house it would be impossible to see. This is the first place that I have visited where I have seen the effects of that wretched insect the Phylloxera. Two whole houses of fine vines had been sacrificed, for Mr. Selwood is of opinion that no milder measure than that of stamping it out will suffice. He believes it to have originated with some vines brought in, and now that he has planted the houses afresh he has been most careful to guard against its introduction. The vines have been taken out of the pots, the roots well washed, and then laid out separately to dry, and no soil but that which is obtained fresh from the park is used. By these precautions he hoped to avoid its introduction again; and the vigour of the plants and their rapidity of growth bore witness to the fact that the treatment had not interfered with them. With

Fig. 4.—EATON HALL.

regard to Strawberries one has to live and learn, and to see how utterly useless it is to write up or cry down any Strawberry from one's own experience. Here the only variety which is found really to answer either for pot culture or out of doors is Sir Harry, a variety that a great many Strawberry growers have discarded. I both saw it and tasted it; and although it lacked the fine flavour of Dr. Hogg and others of the British Queen section, yet the fruit was both large and well flavoured. Therefore all who say only this or that variety is worth cultivating should simply add, in their experience. I found the Peaches in great vigour. Early Magdalen is much liked, being ten days earlier than Royal George.

One of the most characteristic features of the gardens here is a noble glass corridor of 400 feet in length, from whence houses open containing various stove and greenhouse plants. It reminds me of one I think I saw some years ago at Denbies. This corridor is planted with Roses, climbing plants of various kinds, and filled from time to time with plants from the greenhouses. Amongst the Roses which were doing well here was *Eugène Desgaches*, a variety very little grown, and *Cheshunt Hybrid*, of which Mr. Selwood spoke in very high terms—almost as highly as does my friend Mr. Camm in last week's Journal. It is to me a matter of great satisfaction that this Rose is increasing in favour, for I have always maintained that it would be a favourite; and yet how it was sneered upon

by some when it was first exhibited by Mr. George Paul! The exterior of the corridor is planted with the various new varieties of Clematis.

The stoves contained some fine specimens of Orchids, and were really shining with fine masses of *Begonia nitida*, whose snowy whiteness makes it a most desirable plant for winter bouquets; here it is in great request. Amongst Orchids *Dendrobium filiforme* and *Dendrobium Bensoniae* were very fine. It may give some idea of the extent to which flowers are used in such an establishment to hear that three thousand *Euphorbia jacquiniæflora* and *Poinsettia pulcherrima* are used, and other flowering plants in similar proportions. Some time ago an engraving was given in a contemporary of the *Eucharis* house when in full flower, and a wonderful sight it must have been. Now the large plants have been broken up, but very great numbers are still grown.

In the greenhouses and conservatories for winter-flowering plants there is always a large quantity of rare and beautiful plants in bloom. In one the whole roof was covered with *Allamanda cathartica*; while Ferns, *Scutellaria*, *Heterocarpos*, and other plants at the time of our visit made it gay. The Ferns were many of them grown in pans, which were sunk in the beds and thus hidden from view; in another *Camellias* and *Azaleas* were flourishing. The former had been transplanted three or four years ago, and were in wonderfully fine

health. In another Tea Roses ranged at will, and the house was filled with very fine plants. Maréchal Niel had been very grand, but Mr. Selwood found, as a good many have done, that it either blooms itself out, or else that it is a short-lived Rose. I have seen so many this year of what one must write that their glory is departed, that I fear it will require constant renewal, and its claim to be regarded as a good out-of-doors Rose is become weaker every year. Among the unusual things grown in another house was *Musa Cavendishii*, which is grown in considerable quantities for the sake of its fruit for dessert.

Leaving the garden and its varied contents, of which one can give no more than a mere outline, we were brought by Mr. Selwood to the Tea House as it is called, a most perfect gem, situated in the shrubberies; the interior has the walls covered with encaustic tiles from designs by Marks, the R.A. One scene, illustrating Shakespeare's Seven Ages of Man, was most spirited and has been greatly admired, as it well deserves to be, while horticulture finds its place in some representatives of real and fancied flowers, displaying great spirit in drawing and much originality in colouring. Attached to it is a small kitchen with range, where the young ladies of the family prepare the meal when they use the Tea House. It is certainly one of the most charming pieces of thorough artistic work that I have seen for a long time. Coming back through the shrubberies we came on to the front of the house. Here all is also in a state of transition. There are a series of terraces (some five or six in number) reaching down to the river Dee, and these are being altered under Mr. Selwood's superintendence. They had been laid out in some of Nesfield's abominations, but now for American and other plants; and when completed, in the able hands of Mr. Selwood, they will doubtless form a fitting accompaniment to the grand mansion now being erected. In a portion of the grounds near the house there is a Gothic temple, built for the reception of a Roman altar found near Chester, bearing the inscription that it had been erected by the twentieth legion to the fountains and rivers. Leaving the house and descending to the banks of the river we come on a fine iron bridge erected over it, and near it is a small lodge, which has been erected by the noble proprietor for the benefit of picnic parties, who can be here supplied with all the requisites for their *al fresco* enjoyments, and noteworthy for having a remarkably fine specimen of *Ceanothus* growing over it.

The engraving illustrates the Hall as it was until very recently. The Grosvenor Gate by which the demesne is entered close to the city of Chester, a copy of St. Augustine's Ally Gate at Canterbury, through which I have passed many a time as a boy when it was used as a skittle ground, but now happily turned to nobler and better uses as a missionary college, and the river house above spoken of. In a few years the visitor will have much to say of Eaton Hall, for after the completion of the house there is little doubt that the garden will experience the same outlay, and will be made worthy of the noble mansion to which it is attached. I have to express my thanks to Mr. Selwood for the kindness with which he showed us his treasures, and to the kind friend who accompanied me, and to whose good offices I owe the enjoyment of a very delightful day.—D., Deal.

### SYRINGING.—No. 3.

It is not practicable to give any generally applicable directions for the distribution of water by the engine or syringe to the foliage of plants, but a few hints in reference to the matter may not be unprofitable.

In the case of vineries, and especially in regard to Vines which are forced early, it is usual to sprinkle the Vines several times a-day until the eyes break, and with Peach trees in houses a similar practice is resorted to. This practice may assist the eyes to throw off their scales by the softening influence of the water, but that it can or does exert any influence on the flow of the sap, on which the swelling and bursting of the buds depend as well as the growth of the resulting shoots, is extremely doubtful. Heat is the prime instigator of activity; for with cold, though we have water in the soil to its full power of retention, and moisture in the atmosphere to the point of saturation, growth does not take place. And that actual wetting of the rods and spurs of Vines, the branches, shoots, and buds of Peaches, facilitates growth—a more even swelling of the eyes or buds—is extremely uncertain. In fact I have tried both practices—*i.e.*, syringing overhead and omitting it, but affording moisture to the roots and atmosphere, and am bound to say that the results have been invariably in favour of the

practice of non-syringing. It may make a difference when the border and atmosphere has during the resting period been kept dry as dust. Sprinklings may in such cases be necessary to enable the shoots and branches to absorb moisture, and the hardened scales or envelopes of the buds and eyes to be softened so as to admit of their free expansion; but with the soil in a proper state of moisture, which Nature amply provides for, the necessity for repairing any errors of the resting period does not arise, and beyond a few light sprinklings overhead I do not consider any benefit accrues from syringing after the buds or eyes commence swelling. I had this year a vinery and Peach house which were not sprinkled at all, or the evaporating troughs filled with water, until the blossom of the Peaches was showing colour and the eyes of the Vines had broken, and the result is that I shall avoid the drowning practice of starting these subjects in future. In the case of both Vines and Peaches atmospheric moisture is required for growth, but only in the case of artificially heated structures does the necessity arise for sprinklings at an early stage. Cool houses when the borders are in a proper state will give out sufficient moisture to maintain a suitable atmosphere for Peaches until the blossom is set, and for Vines until they are broken, but when leaves are formed we must keep up a moist atmosphere by sprinkling two or three times a-day—morning, noon, and afternoon, wetting every available surface, and in the case of Peaches syringing morning and evening, but not applying water to the foliage at noon, though the house is to be damped. Even in damping considerable judgment needs to be exercised. If the surfaces are moist there is no use in wetting, but if at all dry they should be moistened, and in the case of syringing the leaves ought to be dry before they are again made wet. When artificial heat is employed the evaporating troughs ought never to be empty of water. Artificially heated structures require considerably more moisture than those dependant upon solar heat, except in hot weather, when the difference will not be material.

There is a difference in opinion as to whether any variation ought to be made in the moisture at the time of flowering of the Vines and Peaches. I do not perceive why any deviation should be made. Nature makes none. It certainly is not advisable to syringe Vines, for Nature would never have protected them with leaves above had the inflorescence required wetting; but as to Peaches the blossom is disposed so as to receive descending dew and rain, and yet under glass and even outdoors I have seldom noticed a case of non-setting from a too-dry atmosphere, the border being in a proper state of moisture. Atmospheric moisture is unquestionably necessary to the maintenance in health of the blossom of the Peach and flower of the Vine, an overdry atmosphere causing the drying-up of the stamens and early fall of the petals. In the case of Vines overdryness causes the hood (corolla) to be retained too long; the stamens from their weakness not throwing, the anthers being mostly sterile or too feeble to cast the hood, and united with a pale sickly small ovary and corresponding stigma. Set such blossom and fruit may, but in the case of a Peach it will not swell, and in the case of a Vine the berry will be stoneless. I am not going to the extent of advocating syringing, though that is better than a parching atmosphere, but I do submit that the best set is had in Peaches with a congenial well-aired atmosphere, and with Vines a moist atmosphere is necessary.

I have known instances of both Peach and Vine pollen being as it were bound up by a dry atmosphere which upon the application of moisture has caused its liberation. Syringing in the case of a high temperature and dry atmosphere would ensure the liberation of the pollen, whilst the current of air produced by the passage of the water would tend to distribute the pollen. Still, when a due regard is had to the maintenance of a congenial atmosphere the necessity of syringing in the flowering period does not arise, and, as I accept the term, syringing is likely to be more hurtful than conducive of fertility.

Of the necessity of a congenial atmosphere, but at the same time free from accumulation of moisture, we have abundant testimony in the Melon. Let the roots be dry and cold and the air parched, and the sterility of the plants will be as marked as in a close moist atmosphere. Due moisture for the roots and atmosphere, with free ventilation—the flowers well nourished and the pollen well aired—we need not apprehend any difficulty in the setting of fruit, for in a wet season we may have exuberant growth without a corresponding yield of seed, but in a comparatively dry season we have moderate growth yielding seed abundantly.

Cultivators amateur and professional know well the advantage of a moist atmosphere for the maintenance of flowers in beauty, for when the atmosphere is dry the evaporation is excessive and the petals soon drop; hence the shading of plants in flower, which lessens evaporation and secures moistness in the atmosphere without resorting to sprinklings, which are destructive of the beauty of flowers. An overmoist atmosphere is equally disastrous to flowers as syringing overhead, the flowers of most plants in a close moist atmosphere spotting and not unfrequently decaying. Everybody knows that flowers are damaged by rain and impaired by bright sun, hence syringing is avoided; shade is given, making up for any lack of moisture by more liberal waterings at the roots. Of course this does not apply to the ripening of seed, a flower expected to seed requiring light, air, and moderate moisture.

The growth of foliage and fruit demands moisture, and it is a mistake to leave off the sprinklings which have been recommended when the fruit commences ripening. The ripening of fruit cannot be satisfactorily accomplished without moisture, and any danger of injury therefrom may be avoided by freer air-giving. In cool houses less moisture will of course be required than when much artificial heat is used, but in all instances moderate atmospheric moisture is essential to well-swelled juicy fruit. Exception must be had to fruit such as the Melon, which does not during ripening increase in size. If the moisture be too great the flavour will be insipid, the fruit not unfrequently cracking.

Moisture must in the case of Peaches be continued after the fruiting. The wood for future bearing requires to be matured and the buds to be fed. After the fruit is gathered I again resort to syringing, and do not leave it off until the leaves show that their office is drawing to a close. Peach trees devoid of moisture after the fruit is ripe will become infested with red spider, and the flower buds will certainly drop in the spring.

Plants making fresh growth require a moist atmosphere; indeed, at most seasons of the year moisture is necessary, though considerably less is needed when the plants are at rest. As a rule stoves require from February to October damping and sprinkling three times a-day—morning, noon, and when the house is closed or shortly afterwards. Syringing overhead I do not consider advisable at noon; the main point to be attended to is to afford moisture available for evaporation. Greenhouses will not require any damping during winter, and in summer from April to September damping may be practised in the evening or afternoon from 5 to 6 p.m. Plants liable to insects or in a growing state may be syringed overhead twice a-day—morning and evening, especially the latter; but the ventilation should be good, or the sun falling powerfully upon the leaves whilst wet will cause them to spot. Pelargoniums are so liable to spot, that unless thoroughly ventilated water should not be given overhead, and is best omitted at least after March, avoiding condensation by ventilation at night. Houses in which a high temperature is maintained, as Cucumber and Melon houses, require considerably more moisture than those kept at a lessened temperature, and those in which the temperature is maintained by hot-water pipes will need fully three times as much moisture as those in which heat is maintained by fermenting materials.

As the correct supply of moisture is one of the most important elements required for successful culture, I have come to a few deductions which may be of service. They are as follows:—The leaves of all plants ought to be dry by the time the sun's rays are powerful. If the leaves are wet from the condensation of moisture during the night, air should be early admitted so as to prevent the water from being so highly heated as to scald the leaves, or shade should be given. The principal moisture should be at night, and the foliage of all plants (except the Filmy Ferns, &c.) should be dry for the most part of the day. There is greater need of moisture overhead when growth is being made than when it is mature, but moderate moisture only ought to be given when the foliage or growths are tender. It is usual to insist upon the water which is employed for syringing being of the temperature of the house. This is only important when the growths are tender. Peaches, Strawberries, and Roses have hard-textured leaves, and are prone to attacks of red spider. These after the leaves are full-sized may with impunity be syringed with water 20° less than the temperature of the atmosphere. I have noted the beneficial effects of syringing trees against walls, especially Peaches and Roses, with water in some instances as much as 30° below the temperature of the air. Are we not to attribute the cleansing of the foliage of plants to the lower temperature

of the rain to that of the atmosphere? All moisture—dew and rain, is at a lower temperature in summer than the mean of the atmosphere.—G. ABBEY.

### THE SIR J. PAXTON STRAWBERRY.

"J. J.'s" experience of Sir J. Paxton is identical with mine. In March, 1875, we took a garden (Ryde, Isle of Wight) destitute of Strawberries, and immediately obtained from a famous nurseryman two hundred strong plants in pots of Sir J. Paxton, hoping to obtain little fruit from them that year. The plants grew most vigorously, but not half flowered, and those that did hardly produced any fruit. A friend advised the destruction of all the non-flowering plants, but they looked so strong and healthy we thought we would give them a further trial. In August we moved about half, thinking they were too closely planted, and at the same time put in young plants of all the best kinds of Strawberries—Sir C. Napier, Dr. Hogg, Margaret, Constante, President, Mr. Radclyffe, &c. These young plants are now bearing quantities of the finest fruit. It is impossible to say which kind succeeds best, all are so good. Sir J. Paxton (though double their size and growing side by side with them) is a complete failure. Half the plants again did not flower at all, and have been thrown away. The remainder flowered feebly, but have produced little fruit, and that very small. Yet the plants are of great size, with splendid large leaves and strong runners. We are now removing Sir J. Paxton entirely. Our soil is light but good.—W.

"J. T." (see page 12) must now down the leaves of Sir J. Paxton, and give the plants neither water nor manure, and next year they will bear. Some years ago Trollope's Victoria served me the same. The plants were all leaves, as high as Rape. I treated them as above and succeeded.—W. F. RADCLYFFE.

### THE ROYAL HORTICULTURAL SOCIETY.

In a very few weeks the Royal Horticultural Society will have to be reconstituted. Those who have the charge of this work might, I think, take some useful hints from the Volunteer Rifle Association, which goes on and prospers. The higher and richer classes naturally take the lead, but the association and rifle corps movement embrace all classes, the qualification being the taking an interest in the object. The subscription is one guinea. I believe that if those interested in horticulture and the improvement of flowers, fruit, and vegetables would now all pull together, would join the amended Society themselves and canvass their friends in their districts, we should soon have a strong representative society.

The leading nurserymen have influence. If they will send out with their catalogues and invoices, and back-up a short statement showing how much good work the Society does at its Committee meetings and by its experiments at Chiswick, and pointing out that its work is essentially distinct from that of all local societies however influential, and ending with a strong appeal to all lovers of their gardens to lend a helping hand at once; and if the powerful gardening press will circulate slips with their papers, I believe that such a list of suitable Fellows would come in as would very soon put the Society firmly on its legs. It would, of course, be necessary to prove that the liability of Fellows is absolutely limited to the amount of their guinea subscription. As in the case of the Rifle Association we should be associated with the local societies, and perhaps have one great annual field day, to which representatives would come from all parts of the country.—GEORGE F. WILSON.

### THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 10.

In referring to the nursery of the Messrs. Loddige I should have noted that a publication took its name from that establishment, entitled "Loddige's Botanical Cabinet," which was in course of publication between the years 1817 and 1834, extending to the respectable length of thirty-four volumes. The firm was also remarkable for its dexterity in packing plants so as to enable them to keep their vitality during a long sea voyage, by suspending their natural growth till they reached the climate for which they were intended. This plan seems to have occasioned some wonderment forty or fifty years ago, and was frequently tried successfully with Camellias and allied plants. These were placed in layers and well packed with an

abundance of sphagnum, which was trodden or pressed down as tight as possible. Surrounded thus by a bad conductor of heat, and one which is very reluctant to part with its moisture, the plants had no injury during the transit to our Antipodes, which in these times can be, by the help of steam, managed so much more speedily than in the days of our esteemed grandfathers.

Crossing the Thames, however, to complete my account of Lambeth and its vicinity, I must observe that really the residents in what is sometimes called the "Court Suburb" have no reason to plume themselves upon the name of Kensington, since a despised Surrey suburb can boast of the same name with only the difference of a letter. "Kensington" and "Kennington," as I now consider, are merely modifications of the "King's Town," taking rise in a period when the word "town" was occasionally applied to a solitary abode, supposing it was occupied by a person of importance. The historian of Lambeth I know speaks of Chenintume, a king who, it is conjectured, gave the place its appellation, but the proofs are slight indeed—quite as much so as those which would associate Prince's Road with the Black Prince, who did once live at Kennington as it is thought. More probable is it, I should say, that Prince's Road had its name from Frederick, Prince of Wales, of the Georgian era, a well-known frequenter of Vauxhall in its palmy days. Kennington, then, the "town" or "place" of the king, formerly had a palace, at which some of our earlier monarchs resided, until the reign of Queen Elizabeth; however, we have nothing definite about it. Then we find it in the possession of Sir Noel Caron, ambassador from the Netherlands, who, having a grant of the manor, built himself a mansion called Caron, or Caroon House, dying in 1624. And there is a curious account of this estate drawn out by the Commissioners who surveyed the manor by the order of the Commonwealth, which proves Sir Noel had had a fancy for fruit cultivation. The chronicle mentions "sundry small gardens, also one great garden adjoining to the south and west sides of the said mansion, planted with trees and gardener's fruit, with one other garden on the north side of the mansion planted also with young trees, and wherein stands one pump." This north garden, I presume, extended towards the river as far as the present Wandsworth Road, perhaps across it, and I regard a little grassy enclosure with interest on which grow some good old trees, and which overlooks Kennington Oval, for I believe it to be a relic of the garden of Sir Noel Caron. Subsequently we read of a transfer of the manor by Chancellor Clarendon to Sir J. Whicheott, when gardens and orchards are again mentioned. There was in addition an extensive deer park, which comprehended Kennington Oval and Common, stretching west towards Claylands, where it was bounded by a stream called the Effra. It might be supposed, from the fact that many coins were dug up in the nursery grounds of Messrs. Chandler & Buckingham in the Wandsworth Road not far from Vauxhall Bridge, that this land belonged to the Caron estate.

Few horticulturists know anything of this Mr. Chandler, though he deserves some little repute as the illustrator of a work on the Camellia, published in 1831. The air of Vauxhall has not, I fear, improved during these recent years, but at the time Mr. Chandler was devoting his attention to Camellia culture the plants would thrive in the open air; he enumerates eight sorts that flowered freely against a north-west wall. This nurseryman produced many varieties from seed. One of these, Chandleri (also versicolor in the "Botanical Register"), being reputed of great excellence. This was originated in 1819 by Mr. C. from the seeds of *C. anemoniflora* or "Waratah," crossed with other varieties; and in the same year he produced from the seeds *C. Altheiflora* and *C. conceinna*; and Loudon notes as a curious circumstance that about 1822 Mr. Chandler raised *C. Aitoni* and four more varieties from the seed in one capsule of *C. pomponia*.

Very near this nursery garden was the orchard belonging to a Mr. Phillips, who for his success in fruit culture received two gold medals from the Society of Arts. And, indeed, in the early part of this century fruit trees were numerous all along the road to Wandsworth; the yield in ordinary seasons was quite up to the average or above it, though the gardeners, professional or amateur, did not pursue quite the same methods that were common in the Middlesex orchards, where the practice of manuring was carried almost to excess. One of the "oldest inhabitants" of Kennington, and quite a local celebrity, was a nurseryman of the name of Michelson.

He had antiquarian tastes, too, so that visitors to the place could obtain much information from him about its history, especially as he reached the age of one hundred, or very nearly, though our anti-centenarian philosophers would doubt this, as they have other instances where the venerable age rested chiefly on the testimony of the individual himself. Mr. Michelson does not figure in our annals of gardening as a cultivator of rarities or a producer of varieties, though he plodded on for a good many years at his pursuit, and modern Kennington knows him not or his nursery ground as such, for o'er its surface flies the ball of the cricketer, and the air off resounds with the shout of applause at the skill displayed by bowler or batsman. In point of fact, when Kennington Oval was first reclaimed from its wilderness condition (for it was once much in the same state as the common adjacent, which once served south Londoners as an assembling ground) in the reign of George III. it was formed into a nursery garden, which an historian of the past declares was "peculiarly delightful." There were then but few houses in the vicinity, and Harleyford Road leading to the Oval was quite rural in aspect. On the decease of Mr. Michelson, or soon after, somewhere about 1830, the Oval was cleared of its plants and turfed, to be henceforth devoted to very different uses, and one by one the nurseries of that neighbourhood have disappeared to meet the increasing demand for building ground.

It may be recollected by the reader that I have made slight allusion to the history of Vauxhall Gardens. Recent investigations lead me to think that the garden mentioned by some authors as the Old Spring Garden at Vauxhall, or Fox or Fankes Hall, was distinct from the gardens we read of in the time of Queen Anne and the Georges. If we take the earliest account we have of the Old Spring Garden it gives us quite a different idea of the place from that we obtain in the "Spectator," where Addison descants upon groves, shady walks, carolling birds, and the like, evidently painting Vauxhall from the life, though he gives us ideal personages. Mingis, describing the Spring Gardens he saw in the reign of Charles II., states that it had grass and sand walks which divided squares of 20 yards each, which were enclosed with hedges of Gooseberries, and within were grown Roses, Beans, Asparagus, &c. This was manifestly a nursery garden on a moderate scale, with, we will suppose, seats here and there for visitors, while the more modern Vauxhall was chiefly shrubberies. This nursery garden then of 1663, which, if we were to guess at its position, was somewhere near the Thames—(it may be, as one author says, just opposite the New Spring Gardens)—had some singularities. It had walks laid down with grass as well as "sand," the latter we will hope was what modern folks call "gravel;" and the mode of growing flowers, fruits, and vegetables all in the same bed was original, if not according to the plans of the present race of gardeners. Long before the New Spring Garden the Vauxhall which was extant when Victoria came to the throne had yielded to the force of time. The Old Spring Garden had been seized by the builders, and now we cannot discover its locality, though it is thought that it faced the gardens which made Vauxhall still more famous. "Spring Garden," as it would appear, was a phrase formerly applied in a loose manner to a number of suburban resorts where persons went out for recreation or to obtain fruit. Was it because in many of these gardens they had springs or fountains to impart a sensation of coolness agreeable to the visitors and also to afford a ready means of watering the plants and shrubs? or was it because the proprietors of these gardens, by the introduction of a variety of plants and flowers, endeavoured to present to the eye a spring aspect all through the summer season?

Not far from Kennington is a place which has passed through odd vicissitudes, and to which a passing comment must be given. The Surrey Zoological Gardens, Walworth, originally covering about 15 acres, were taken by some gentlemen more hopeful than practical, in the hope that by their means they might be able to develop a liking for botanical pursuits in the minds of holiday-making Londoners. It was in the early part of the reign of William IV. that the establishment was opened as a "botanical garden." It was stored with a variety of exotics, and arrangements were also made for the delivery of lectures, *al fresco* I suppose. But the scheme did not answer, and so Mr. Cross removed his menagerie to Surrey from Exeter Mews and other animals were added until a very fair zoological collection was brought together, though it could not rival the display in Regent's Park. At the time the Horticultural Society was passing through an unpleasant crisis, and Fellows

came forward with various propositions for making South Kensington more attractive, it is a wonder that no one proposed the introduction of a collection of animals "all alive, oh!" I have no doubt some leopards, bears, camels, and monkeys would have caused a rush to the gardens, for one hears frequent complaints about the distance of the Regent's Park from west-end resorts. Surrey Gardens, however, despite its animals and its monster panoramas of Hecla and Vesuvius, had to succumb to the changes time brings about. It was closed, the contents sold, and after an interval we find it the temporary abiding place of St. Thomas's Hospital. Then again it became a place of popular resort, with modifications to suit the latest tastes of the age.—C.

## PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

**MONOPHYLLA RACEMOSA.** *Nat. ord., Gesneraceae. Linn., Tetrandra Monogynia.*—Native of New Grenada. A stout plant with a raceme of white flowers.—(*Bot. Mag., t. 6233.*)

**DRACENA SAPOSCHNIKOWI.** *Nat. ord., Liliaceae. Linn., Hexandria Monogynia.*—"This is a species of tall, tree-like habit, of which the native country is unknown. It has been long in the Kew collection, but did not flower till the spring of 1875. The plant was described and named by Dr. Regel in 1871 from specimens which flowered in the garden of the Russian gentleman after whom it is named, who procured it from Herr Wagner of Riga. It has close allies both in Tropical Asia and Tropical Africa. It is remarkable for its very dense rosettes of rigid, sword-shaped leaves, and for its very small flowers, which, although the panicle is ample and diffuse, are less than those of any other known species."—(*Ibid., t. 6234.*)

**COTYLEDON TERETIFOLIA.** *Nat. ord., Cruciferae. Linn., Decandria Pentagynia.*—Flowers yellow. "In South Africa this genus is chiefly confined to the south-western corner of the continent, most of the species occurring in the Cape Town district. To this *C. teretifolia* is rather an exception, it being found as far to the east as the province of Graaf Reinet and Somerset, where it forms an undershrub on the hills. Living specimens have been received at Kew from Mr. Wilson Saunders in 1873, and from the late Mr. D. Hanbury, which flower in the month of July."—(*Ibid., t. 6235.*)

**MILLA LEICHTLINII.** *Nat. ord., Liliaceae. Linn., Hexandria Monogynia.*—Flowers white. "It is a native of the Chilean Andes, and was imported to Europe by our indefatigable correspondent Max Leichtlin, Esq., who presented a living plant and seeds to the Kew collection, where it flowered at the latter end of January, 1874. It is quite hardy, and the flowers are slightly fragrant."—(*Ibid., t. 6236.*)

**ODONTOGLOSSUM HALLII.** *Nat. ord., Orchidaceae. Linn., Gynandria Monandria.*—Flowers yellow banded with brown. "It is a native of the Temperate Cordilleras of Peru and New Grenada, where it attains an elevation of 8000 feet. It was flowered by Messrs. Backhouse of York in March, 1866."—(*Ibid., t. 6237.*)

**HEPTAPLEURUM POLYBOTRYUM.** *Nat. ord., Araliaceae. Linn., Pentandria Monogynia.*—Flowers green. "A native of the mountain forests of Java, where it attains the elevation of 4300 feet, and whence specimens from various collectors are preserved in the Kew herbarium. It has been long in cultivation at Kew, having been received in 1860 from the late Dr. Miquel, at that time Professor of Botany, and in charge of the Botanic Gardens of Utrecht. It flowers in the winter months, and is probably common in continental gardens, as it appears in Linden's catalogue under the name of *Paratropia Teysmanniana*, the provisional name under which it was received at Kew from Dr. Miquel."—(*Ibid., t. 6238.*)

**PEACHES.**—"Hale's Early is undoubtedly the best early Peach in cultivation, ripening on the open wall some days before the Early York or Acton Scot. The fruit is also of larger size and finer in quality than any other early Peach. It may be described as of medium size, roundish, with a deep suture on the side. The skin is of a dark crimson colour on the exposed side, with a thick coating of down, shading off to a greenish yellow streaked with red; when grown under glass the colours are much brighter and clearer. The flesh is of a dull greenish yellow, very tender, melting, juicy, and richly flavoured, and parts freely from the stone. The flowers are large, and the leaves have round glands. This fine Peach comes to us from America. It has been now for several years in cultivation in this country, so that its high merits are becoming pretty well known. It is especially recommended by Mr. Pearson and others. In constitution it is as free and

vigorous as the Bellegarde, and, like that variety, a certain cropper. *Early Victoria* is another fine early Peach, a day or so earlier than the Early York. It is exceedingly well adapted for cultivation under glass. For wall culture it is somewhat tender. The fruit is rather below medium size, roundish; skin very thin, bright red on the exposed side, pale greenish white with small red streaks in the shade. The flesh is yellowish white, very juicy, tender, and melting, with a rich flavour. The flowers are large; leaves without glands. This fine Peach was one of the first of the seedlings raised by Mr. Rivers from the Early York, and was named in honour of Her Majesty Queen Victoria."—(*Flor. and Pom., 3 s. ix., 157.*)

## THE GALLOWAY ROSE SHOW.

NEWTON STEWART, N.B.

It was certainly a somewhat startling request when I received an invitation to come down to Wigtonshire to judge at a Rose Show, and it was odd to find myself after the lapse of nearly half a century once more in this part of Scotland; for as a very small boy I had been sent for some months to a school at Stranraer, and a most Dotheboys Hall sort of place it was. Happily I forget the name of my Squeers, and so cannot visit him with my denunciations; but bad food, uncleanness, and plenty of caning were, I well remember, the principal features of the "Academy," and when these were represented my stay was not prolonged. And now to find myself once more near the place! Indeed when I went to Castle Kennedy, within two or three miles of it, was a strange thing. When I told some friend that I was going to judge at a Rose Show at Newton Stewart, I was met with the exclamation, "What! In that out-of-the-way place!" Yes, truly; and let me say that this apparently Quixotic enterprise has been originated, planned, and carried out by the indefatigable exertions of the Rev. W. G. Mackenzie, the clergyman of All Saints, and in a manner which reflects the utmost credit on his energy and pluck.

The Exhibition was held in a large and convenient public room in Newton Stewart, and was remarkable for one characteristic—it is the only one as far as I know, and certainly the only one at which I have been present, where exhibitors from the three kingdoms have met together in the fray. Mr. Cant came from Colchester, Mr. Dixon from Newtonards in Ireland, and Messrs. Robertson & Galloway from Helensburgh, besides, of course, several local nurserymen. Mr. Cant swept the board, sending some of his grand Roses, which acted rather as what the Yankees call "eye-openers" to some of the local gardeners, who, after scanning his boxes for some time, at last came to the wise conclusion that "they Roses must have all been grown under glass." But certainly they had never seen a southern Rose show, and so could not account for the size and beauty of his productions. I can imagine how some of them would stare to be landed at the Crystal Palace or the Alexandra and see the rows of boxes filled with the productions of our southern Rose-growers. And let me say that very excellent blooms were sent by both Mr. Dixon and Messrs. Robertson and Galloway, while some of those from the gardens in the neighbourhood were fresh and beautiful. The terribly cold and severe season had told against them; and Mr. Mackenzie, who lives in a place where all the winds of heaven have free play and Eolus holds his court, was not able to send a bloom. The enthusiasm which an exhibition stirs up was well seen here. It will hardly be believed, but it is none the less true, that as much money was taken at the doors with this small town of two thousand people as at Maidstone with its eighteen or twenty thousand, and this without any adjunct of band, fireworks, cats or dogs, cocks and hens, &c., which in so many places seem to be required to make a Rose show pay. Nor was this enthusiasm the less seen in a visit I paid to the garden of an excellent draper in the town, where all sorts of contrivances for forwarding or retarding the blooms were adopted; an enthusiasm which I am glad to say met its reward in enabling Mr. M'Morran to carry off the first prize in his class.

I subjoin a prize list, which will be of interest to some even in the south, as showing of what stuff our northern friends are made. I have again to speak of the utmost kindness and courtesy with which I have been received; and it will be to me ever a pleasure that my trip here has enabled me to make the acquaintance of the indefatigable pastor of All Saints; and the hospitality and kindness with which I have been received will go far to obliterate the unpleasant taste in my mouth which the recollections of my boyish days at Stranraer have left behind.—D., Deal.

Class 1 (nurserymen).—Forty-eight H.P. Roses. 1, B.R. Cant, Colchester. 2, J. Service, Maxwelltown. Class 2 (nurserymen).—Eighteen Tea-scented and Noisette Roses, distinct varieties. 1, Robertson & Galloway, Glasgow. Class 3 (open).—For best six varieties in pots. 1, J. Hannah, gardener, Monreith. 2, J. Fairgrieve, gardener, Castlewigg. 3, J. Tweedie, gardener.

Greenlaw, Castle Douglas. Class 4 (open).—Thirty-six Roses, including six Teas and Noisettes. 1, B. R. Cant, Colchester. 2, A. Dickson & Sons, Newtonards. 3, T. Smith, Stranraer. Class 5 (open).—For the best stand of the following twelve fragrant Roses:—La France, Devoniensis, Maréchal Niel, Charles Lefebvre, Louis Van Houtte, Gloire de Dijon, Alfred Colomb, Marie Baumann, Bessie Johnson, Abel Grand, Sénateur Vaisse, Camille Bernardin. 1, B. R. Cant. 2, Dickson & Sons. Class 6 (open).—Twelve best Roses of 1873, 1874, 1875. 1, B. R. Cant. 2, Dickson & Sons.

Class 8 (open to gentlemen's gardeners in Galloway only).—Twenty-four H.P. Roses. 1, A. Kirk, Ernespie. 2, J. Fairgrieve, Castlewigg. 3, J. Norval, Galloway House, Garliestown. Twelve Hybrid Perpetuals. 1, A. Kirk, Ernespie. 2, G. M'Meeking, Logan, Stranraer. 3, T. Duff, Kenmore Castle. For twelve Tea-scented and Noisette Roses. 1, G. M'Meeking. 2, J. Fairgrieve. 3, W. Muir, Corbie, and A. M'Morran, Glasserton, equal. Class 9 (open to Galloway amateurs only).—For twelve best Roses of any description. 1, D. Thomson, Castle Douglas. 2, T. M'Morran, Newton Stewart. 3, H. E. Maxwell, The Airlour, Portwilliam. (Open to Wigtonshire, Minnigaff, and Kirkcubrecht amateurs only).—Twelve H.P. 1, T. M'Morran. 2, Mrs. Colvin Stewart, Newton Stewart.

Class 11.—Centre piece, decorated for a dinner-table with Roses, Ferns, and ornamental Grasses. Section A. For ladies. 1, Mrs. G. Vans Agnew, Newton Stewart. 2, Miss A. M'Morran, Newton Stewart. 3, Mrs. Kennedy, Greenlaw, Castle Douglas. Section B.—For gardeners. 1, T. Duff. 2, J. Bryden, Dunragit.

### NOTTINGHAM HORTICULTURAL SHOW.

THIS Exhibition opened on the 6th and closed on the 10th inst., and has proved in every respect a great success. Much has been said lately in these pages about having more than one or two-day shows. At Nottingham ample provision was made to have the last day as interesting as the first. The cut Roses which were staged on Thursday morning were mostly decayed by Friday night, and the large tent in which they were shown was completely filled with fresh exhibits on Saturday morning. Fruit—especially Figs, Strawberries and Peaches—were somewhat decayed on Monday, but Grapes, Pines, and such like were as fresh as on the first day. As to plants, with the exception of a few Todeas and tender Ferns, not one of them appeared to have suffered the least injury.

Locally the Exhibition is spoken of as "The Rose Show," but it was an excellent display of all kinds of horticultural productions. There has been nothing like it in the neighbourhood since the Royal Horticultural Society's Exhibition in 1871. The exhibits filled seven spacious tents, and everything was arranged and carried out in first-class order under the care of Mr. Kirk, the able and courteous Secretary.

**ROSES.**—The display was an excellent one, every class being keenly contested. For seventy-two distinct blooms Mr. Cant of Colchester was first with splendid blooms, among which Alfred Colomb, Baroness de Rothschild, Duke of Edinburgh, Horace Vernet, Louis Van Houtte, Victor Verdier, Prince Arthur, and Felix Genere were very conspicuous. Messrs. Cranston and Mayos, Hereford, were second with a fine group, including some extra fine blooms of Reynolds Hole, Madame Furtado, Fisher Holmes, and Monsieur Noman. Messrs. Davidson & Co., Hereford, were third; and Mr. Henry Frettingham, Beeston, fourth. Messrs. Davidson & Co. were first for forty-eight sorts; and Mr. House, Peterborough, secured the same position for thirty-six, with Mr. Merryweather, Southwell, second. The two latter gentlemen held the same position for twenty-four blooms. In the amateurs' class for forty-eight blooms the Rev. Canon Hole, Cauntun Manor, was very far in advance of all others. His stands were prominent throughout the tent for the large size and great substance of the blooms. As we heard a famous Rose-growing nurseryman say, they bore the real Cauntun stamp. The Rev. E. N. Pochin was second; and in the class for twenty-four this arrangement was revised. For eighteen Roses the Rev. Canon Hole was again first with magnificent blooms, amongst which we noted Madame Lacharme, Baroness Rothschild, Marie Baumann, Capt. Christy, Maréchal Vaillant, Etienne Levet, and Reynolds Hole. The latter Rose was shown in the finest possible condition by many competitors. Mr. William Harrison, Nottingham, had the best bloom amongst amateurs with Dr. André.

For the best twelve Roses of any variety Mr. Merryweather was first with splendid flowers of Etienne Levet; Mr. Curtis, Chatteris, being second with Baroness de Rothschild. For Tea or Noisette Roses the Rev. Canon Hole was first with some fine Maréchal Niels, Madame Berard, Céline Forestier and Devoniensis. Mr. Laxton, Stamford, exhibited the new English-raised seedling Rose Dr. Hogg, a splendid crimson variety of great promise. As usual, local exhibitors appeared in great force, and a highly creditable display they made.

Plants occupied a number of large tents. Many splendid specimens were shown. For ten flowering and ten foliage

plants in the open class Messrs. Lucombe, Pince, & Co., Exeter, were first, and finer plants were never seen about Nottingham. Mr. Cypher, Cheltenham, was second with excellent plants; and Mr. Dixon, Beverley, was third with a group in which there were many specimens of great merit.

In the class for sixteen foliage and flowering plants Mr. Pilgrim of Cheltenham was first; Mr. Tudgey, Henwick Grange, Worcester, second; and Mr. Meadows, gardener to C. J. Cox, Esq., Basford, Notts, third. In each of these groups some capital specimens were shown.

For a collection of new and rare plants Mr. B. S. Williams secured the first place, Mr. Dixon second, and Mr. Cypher third. Many very choice plants were shown in each collection. Mr. Williams especially having such rare and beautiful subjects as Bertolonia Van Houttei, Croton majesticum, Sarracenia Williamsii, &c.

In the collection of plants grouped for effect Mr. B. S. Williams was again first with a splendid group, Mr. Cypher being second, and Messrs. Lucombe, Pince, & Co. third. Several local exhibitors staged highly creditable collections; notably Mr. Thacker, Notts, whose group, although small, was arranged in splendid style.

Orchids were well shown by Mr. B. S. Williams in the nurserymen's class; and Mr. Mitchell, gardener to Dr. Ainsworth, Manchester, had some admirable specimens in the amateurs' class.

For dinner-table decoration plants Mr. Kerr, gardener to G. C. Hill, Esq., was first with well-grown plants. Fuchsias, Caladiums, Achimenes, and many single stove and greenhouse plants were shown in fine condition. The Ferns from E. J. Lowe, Esq., Highfield House, Notts, would have furnished an ordinary show in themselves. Many new and rare, as well as splendid, specimens of old varieties came from this gentleman.

Dinner tables were very attractively arranged, Mrs. Cypher being first, Miss Bridget second, and Mrs. James Cypher third. The latter was quite equal to the first, and much more elegant and superior to the second.

The Fruit prizes were rather weak; Mr. Gilbert, Burghley, was first for a collection of eight sorts with some fine Muscat of Alexandria and Black Hamburg Grapes, splendid Pines, Melons, Figs, Peaches, Strawberries, and Cherries; Mr. Bannerman was second. For two Pine Apples Mr. Tudgey was first, Mr. Miles second, and Mr. Gilbert third. None of these fruits were very superior. In single Pines Mr. Gilbert put in a better appearance.

Mr. Bannerman was first for three bunches of Grapes with Black Hamburg, Madresfield Court, and Muscat of Alexandria. Mr. Edmonds, gardener to his Grace the Duke of St. Alban's, Bestwood Park, Notts, was second with well-finished bunches of Black Hamburg, Muscat of Alexandria, and Canon Hall Muscat. For two bunches of Grapes Mr. Bannerman was again first with Foster's Seedling; Mr. Booth, Osaston Manor, being second with very good Muscat of Alexandria. Mr. Gilbert was both first and second for Melons with Hero of Bath and Victory of Bath, both first-rate green-fleshed varieties. In the scarlet-fleshed section Mr. Bannerman was first with Read's Hybrid, Mr. Gilbert being second with Prince's Favourite, and Mr. Swanwick third with Monro's Little Heath. Peaches, Strawberries, and other small fruits were shown in large quantities and first-rate order.

Vegetables were rather scarce, but excellent in quality. Mr. Miles, Wycombe Abbey, Bucks, was first for the collection, Mr. Arkell was second, and Mr. Smith, Cheltenham, third. Potatoes, Cucumbers, Tomatoes, and other vegetables were all well shown; and there was a very attractive display of Mr. Laxton's new Peas. For these Mr. Miles was first with William I, Dr. Hogg, Fillbasket, Supplanter, and The Shah.

### THE ROSE ELECTION.

THE time has arrived for testing again the merits of the different varieties of our national flower, and with the consent of our Editors I propose to hold the annual poll, and to call in the voting papers about the end of August. This year is the general election.

The first question is, Name the fifty best Roses of any variety, and underline or mark the best twenty of these. The other question that I propose to ask is, Name what you consider the best stock for Roses. Replies to one or both of these questions are requested by any interested in the subject.

—JOSEPH HINTON, *Warminster*.

### NOTES AND GLEANINGS.

THE forthcoming SHOW OF THE ROYAL HORTICULTURAL SOCIETY on the 19th and 20th inst. at South Kensington, and which is also the last horticultural show of the London season, promises to be one of more than usual interest to horticulturists. In addition to the prizes offered by the Society for Roses,

plants, &c., many of the leading nurserymen are going to exhibit large groups of miscellaneous plants for the decoration of the tents; and great interest is attached to the annual show of Pelargoniums by the Pelargonium Society, which is to be held in conjunction. Fruit—in competition for the liberal prizes offered by Messrs. Veitch & Sons—will as usual make an excellent display; and the show of vegetables—in competition for Messrs. Carter & Co.'s, Sutton & Sons', Hurst & Sons', and W. Munro's prizes—promises to be of unusual magnitude. The Council has wisely, as we think, reduced the price of admission from 7s. 6d. to half-a-crown, and 1s. on the second day.

—THE LINDLEY LIBRARY does not belong to the Royal Horticultural Society. It was purchased with part of the surplus of the proceeds of the International Horticultural Exhibition and Botanical Congress held in London in 1866, and is vested in the hands of trustees, who will be grateful for any donation. By permission of the Royal Horticultural Society the library is deposited in its rooms.

—THE PELARGONIUM SOCIETY'S SHOW will be held on the 19th and 20th inst. at South Kensington in conjunction with that of the Royal Horticultural Society. The collection of zonal Pelargoniums grown at the Chiswick Gardens on behalf of this Society includes many new varieties contributed by the leading continental raisers; and being well worthy of inspection it is proposed to hold a meeting for that purpose at Chiswick, on a day to be fixed at the annual meeting.

—A FLOWER SHOW among the children of the schools of St. George's, Hanover Square, Grosvenor Schools, and St. Mark's and Hanover Schools, was held on the 10th inst., by permission of the Duke of Westminster, in the gardens of Grosvenor House. The flowers were such as are ordinarily chosen for window culture, and the display, though rather small, was very good. The prizes, consisting of gifts of money, were distributed by the Duchess of Westminster in presence of a large gathering of ladies and gentlemen, among whom were Lady Beatrice Grosvenor, the Earl of Shaftesbury, Mr. Gladstone, Sir Henry and Lady Rawlinson, the Earl of Powis, Lady Somerset, &c. At the close of the distribution the Earl of Shaftesbury expressed his strong sense of the good, both physical and moral, which arose from a true taste for flowers and their cultivation, as being calculated to foster mental refinement and habits of gentle care and attention, and could scarcely fail to inspire a truer and more reverential awe of and gratitude to the Great Unseen Power that watched over all. Mr. Gladstone remarked that the excellent taste which they were now being called upon to foster was a pre-eminently English taste; and he thought he might safely say that as regarded the art and science of gardening, the English nation could well take the prize from the rest of the world; that wherever a garden was laid out—not in accordance with artificial rules and mechanical symmetry—but in such a manner as to please the eye and the sense of the picturesque, such a garden was invariably termed "an English garden;" and concluded by urging on architects and builders of cottages and other dwellings for the industrial poor, never to keep out of sight the importance of the provision of facilities for floriculture.

—SOME POTS OF RHODANTHE MANGLESII are extremely pretty in the conservatory at Kew. Some other annuals are also used with good effect, and among the best are *Schizanthus retusus* and *S. pinnatus*. Some Fuchsias trained to the rafters show to great advantage. It has been remarked that Fuchsias should be seen from underneath, and from that point of view they are certainly very effective. One of the best climbers in this house is *Lonicera sempervirens*, of which the flowers surpass any other Honeysuckle we remember, and quite equal *Gesneras* in brilliancy.

—THE ANNUAL SHOW OF THE ULSTER HORTICULTURAL SOCIETY was held on the 6th inst. in Belmont Demesne, the use of which was granted by Sir Thomas McClure, Bart. The day was extremely fine, and in every sense suited for the holding of a flower show. The exhibits were arranged on stands in three spacious canvas tents. We are informed that never were there heard at any previous show so many expressions of admiration on the part of visitors, nor, in the opinion of the Judges, did they recollect any previous display so excellent in every respect.

—THIS HAS BEEN truly "THE YEAR OF ROSES." Their culture seems to extend more and more over all classes and

places. The Duchess of Westminster, Viscountess Holmesdale, Lady Londesborough, Lady Sutton, and Mrs. E. H. Scott were among the JUDGES who awarded the prizes at the Royal Westminster Aquarium; and a Rose show was held at the Corn Exchange in Mark Lane on the 5th, the proceeds being appropriated to the benefit of the Corn Exchange Benevolent Society. The Show was well patronised and very successful, as many of the Roses exhibited might bear comparison with prizetakers in first-class shows held in other parts of the metropolis.

—THE FLOWER SHOW at the Winter Gardens, Southport, was very successful, and great praise is due to Mr. Campbell, their Curator, to whom the arrangement of the whole was wisely entrusted by the Directors, and who has proved himself well worthy of their confidence. People little imagine that it is the result of many months of labour, patience, care, and perseverance. That Mr. Campbell has shown himself equal to the occasion, working all the while single-handed, is well declared.

—THE COUNCIL of the Royal Caledonian Horticultural Society having resolved to award the NEILL PRIZE every second year in place of every third year as formerly, they have awarded the same for the period from 15th of May, 1874, to 15th of May, 1876, to Isaac Anderson-Henry, Esq., of Woodend, for eminence in botany and horticulture.

—OUR report of the magnificent display of *LILIUM ABRATUM* in the garden of J. MCINTOSH, Esq., at DUNEYAN last year will be remembered. This year the display, we are glad to learn, is likely to be equally fine. Many of the plants are growing exuberantly, the stem of one being already 10 feet in height and not yet showing flower buds. A very few of the Lilies were disfigured by the cutting winds of spring, but the majority of them escaped injury. These Liliams are planted in the borders and are not protected, and their vigour and beauty it is almost impossible to describe.

#### POTATO-GROWING EXPERIMENTS.

A GENTLEMAN in the neighbourhood of Arbroath, who has been for some years experimenting with seedling Potatoes, gives the result as follows:—

"My first seeds from the plum were sown in a cosy corner of the garden. They braired in the first week in May, were thinned out and transplanted early in June, and were taken up early in August; those which did not possess merit being destroyed, and those which gave good promise being preserved. In this first year I was comparatively successful, some of the tubers being 4 ozs. in weight, though were only of the size of Filberts—some early, some late; some red, some white, some streaked; some round, some oval, some like kidneys, &c. Not one speck of disease was seen either on the haulm or on the young Potatoes, and the only misfortune they met with was that a perambulating peacock took a fancy to parade in that particular corner, imagining that the proper display of his feathers was of more consequence than the raising of Potatoes for the million.

"In the following season I chose a plot of ground that was not likely to be suitable for the peacock, but the high winds broke the stems, and I had no tubers. The third season I transplanted my seedlings to an inside border, but they were destroyed in a similar manner. This season I have a few excellent plants. My present stock of seedlings are all from the produce of the plums sowed four years ago. My experience is that the ground should be in a sheltered situation, of a free nature, manured in the autumn, forked over in the spring, the seed sown in April in rows 18 inches apart, the weakest plants thrown away, and the others thinned out to 9 inches apart, while spare plants may be transplanted without loss during suitable weather. Guard against crows, cats, trespassers, and high winds. I have now one more acre planted with the produce of my first sowing, and up this date I have given all the varieties an equal chance.

"I have found those which were most promising to be least profitable. One very beautiful variety has entirely failed; another was decimated by the disease, but with that single exception the whole have been disease-proof. One variety is very similar to the Champion, one to the Fluke, one to the Victoria, one to the Regent, one to the American, one to the Ashleaf. A variety of Kidney is uncommonly prolific. The habits of growth vary exceedingly, some being a speedy growth, low stature, and early maturity; others start slowly, grow

strongly, and take a much longer time to mature. On the whole, there are several superior varieties for garden and field."—(*Montrose Review*.)

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### HARDY FRUIT GARDEN.

APPLE, Pear, Plum, and other trees as standards, pyramids, and bushes, require to be looked over at this time to shorten or remove any superfluous young wood. We have frequently advocated the early removal of any wood that is not required. Even trees that are under the care of good cultivators very often become too much crowded with wood from frequent pinchings. A free use of the pruning-knife is requisite to thin-out both old and young growths, as the fruit cannot be of good quality where it is shaded from the sun. In training young fruit trees the habit of each kind must be taken into account. Some varieties of Apples, Pears, and Plums will make three times as much wood as others, and when there is a large quantity of young growths they ought not to be shortened so close back as on trees where the quantity is not so large. The object of pinching a young shoot in June and July is to cause it to throw-out two or three more growths, so that the tree may be well furnished throughout.

If water is laid on in the garden and it can be applied through a hose and spreader to the trees at this season, they will be greatly benefited by it. In villa gardens near dusty roads the leaves of the trees become choked with dust, and a daily washing overhead during a thirsty period will keep the trees in excellent health. If the trees have a thorough washing, and the ground underneath is mulched with manure, enough water will run on to the ground to keep the roots sufficiently moist. Attention must be given to all wall trees, as they are now making rapid growths. All shoots intended to be saved should be nailed into the wall at once. If Pear trees trained on the horizontal system have not yet filled the wall space allotted to them, the leading growths should be stopped so that a second pair of lateral growths may be formed. Sometimes three pairs may be obtained, but it is not desirable to stop the leader twice in a season.

We are busy amongst the Strawberries, gathering the fruit and layering all the runners that may be required. Black Prince and Keens' Seedling are already rooted and will presently be severed from the parent plants; but even for late crops it is best to layer the runners early in the season. The best crops of fruit are obtained when the roots are matted so firmly round the sides of the fruiting-pot by the end of autumn that the plant may be turned out of the pot and be tossed about like a cricket-ball without breaking.

We have been looking over the Apple trees and find a few fruits eaten by the Apple-boring maggot; it is best to gather all such at once and have them destroyed. Earwigs are also troublesome at this season; they will eat ripe fruits on the walls, and it is best to trap them by placing bean stalks against the walls, into which they crawl at night and may be blown-out in the morning.

### VINERIES.

The early houses from which the fruit has been cut require but little attention at this time. The Vines have been thoroughly syringed to rid the foliage of red spider, applying the water with some force to the wood and glasswork to cleanse it from dirt and to dislodge spiders and other insects. The ventilators are left open night and day.

Late vineries still demand a little attention in stopping the growing shoots and tying the lateral growths into their places. If the laterals are neglected and allowed to ramble about, the Vines look untidy and the permanent growths are injured through becoming too crowded with leaves. As the weather is very warm and the nights are also warm it is well to admit a little air at nights: even if the temperature should fall for a few hours below the usual minimum it will do no harm. As there is no heat in the hot-water pipes atmospheric moisture is supplied by evaporation from the paths, borders, and walls of the house.

Vines in pots intended to fruit next year should now be ripening their growths. If the Vines have not yet been repotted into their fruiting pots, no time should be lost in potting them. We never plunge the Vines in bottom heat at this season. It is not necessary to do so, as some suppose, as growths and roots formed under such circumstances are not so good as those formed when the pot has been placed on an open stage over hot-water pipes. The best potting material is good turfy yellow loam not too heavy; but we prefer it more of a clayey than of a sandy nature. Three inches of the top spit only should be used, and the turf be torn to pieces by the hands. Crushed bones in the proportion of a 9-inch potful to each barrowload of loam, and one part of decayed manure to six, form an excellent compost. Twelve or thirteen-inch pots are large enough for the strongest canes, and the potting material must be rammed in quite firmly. The best variety for pot culture is certainly the Black Hamburgh

or Frankenthal; and the best white Grape is Foster's White Seedling. Buckland Sweetwater when well grown is the best, but it is not so constant; the fruit, when it is not freely exposed to the sun, being rather watery, and the berries wanting in plumpness.

### CUCUMBER AND MELON FRAMES.

A couple of Cucumber lights 6 feet by 8 will produce Cucumbers enough for a large family if the plants are managed so that a few fruits are always coming on. For instance, a brace may be ready to cut, two more may be half grown, two more may be two or three days later, and a few may be in flower. One plant is sufficient for a light 6 feet by 4. The growths must be thinned-out weekly, and those that remain be stopped a joint or two beyond the fruit. Some rich dressing should be applied to the surface once in two or three weeks, and each plant will require about four gallons of tepid water sprinkled over the foliage daily when the frames are shut up at 4 p.m. A little air ought to be admitted at six in the morning, increasing the ventilation as the sun raises the temperature of the frame.

Melons require very similar treatment, but omitting the surface-dressing. Melon plants grown in frames and trained over the surface of the bed are liable to damp or rot-off at the collar of the plant, and many persons, thinking to prevent this, starve the plants for water; no greater mistake can be made, as plants insufficiently watered are more liable to decay at the collar than those that have been well supplied. When the fruit is ripening water must be withheld.

### PLANT STOVE AND ORCHID HOUSES.

Where a number of large specimen plants are grown for exhibition purposes there is now plenty of work repotting or training the growths. The exhibitors seem more inclined to grow greenhouse than stove plants now for exhibition purposes. The plants do not suffer by removal like stove plants, and as a rule they last longer; and this is a great advantage where there are a number of exhibitions in succession. Still there are few greenhouse plants, if any, that can stand against well-grown examples of *Stephanotis floribunda*, *Ixora coccinea superba*, and *Dipladenia Brearleyana* or *D. insignis*. Potting large specimen plants requires to be done with great care. A space of 1½ inch or 2 inches clear should be allowed between the ball and sides of the pot. The drainage should be placed carefully in the bottom, and the potting material must not be allowed to mix with the drainage, which it would do if it was put in without first placing some fibry peat or loam, according to the nature of the plant intended to be potted. *Ixoras* should be potted in turfy peat only, *Bougainvilleas* in turfy loam; *Clerodendrons*, *Medinillas*, *Allamandas*, &c., require turfy loam in various proportions added to the peat. All of them that require to be potted must be done at once, so that the plants may be well established before the winter. Even when repotting is done with the greatest care the plants do receive a check to their growth, and it is better to do the work in cloudy calm weather, as wind is quite as injurious to the plants as sunshine. The house where the plants are placed should be kept rather close and moist for a week or more until the plants are established. Watering must also be carefully performed; either too much or too little will be injurious, and it is of the greatest importance to have the plant quite moist at the roots before potting it. A plant may sometimes show signs of suffering for want of water after repotting, and to all appearance the mould may be wet enough; but let the plant be turned out of its pot again, and the old ball will be dusty dry while the new material is spongy wet. This is the result of potting a plant when it was too dry at the roots. If a plant flags after repotting, and when it is thought to be sufficiently moist at the roots, it may be dewed overhead with a fine syringe, and on no account should recently potted plants be exposed to draughts of air or the direct rays of the sun.

We have repotted many of the cool as well as a few Orchids in the warmer houses. Specimens that have been in the same pots for two or three years are thickly matted with roots, which cling to the sides of the pots. It is a mistake to turn such a plant out of the pot in the usual way. If when the pot is inverted and the rim tapped two or three times on the potting-bench the Orchid still clings to the pot, this is a proof that the roots are firmly attached to the pot, in which case the pot should be broken by a smart blow with a hammer; all the growing points of the roots should be carefully preserved. *Cattleyas*, *Odontoglossums*, *Masdevallias*, *Lycastes*, *Anguloas*, &c., were potted in good fibrous peat and live sphagnum in equal proportions, the pots being from a half to three parts filled with clean potsherds.—J. DOUGLAS.

## HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

HIGHGATE. July 13th. Mr. W. M. Burrek, 6, North Road, Highgate, Sec. WEST OF ENGLAND (HEREFORD). Roses. July 13th. Rev. C. H. Balmer, Credenhill, Sec. CLIFTON, BRISTOL (Roses, &c.). July 13th. Mr. J. T. Jackson, Sec.

**LEEK (Roses).** July 18th. Mr. S. Cartwright, Sheep Market, Leek, Staffordshire, Hon. Sec.

**KILMARNOCK.** Roses, July 18th and 19th. General Exhibition, September 14th. Mr. M. Smith, 11, King Street, Sec.

**TONBRIDGE.** July 19th. Mr. W. Blair, Hon. Sec.

**ROYAL HORTICULTURAL SOCIETY, SOUTH KENSINGTON.** July 19th and 20th (Roses, &c.). November 8th (Fruit).

**THORNTON HEATH.** July 21st and 22nd, and September 1st and 2nd. Mr. W. Raines, 10, St. John's Villas, Bensham Manor Road, Thornton Heath, Hon. Sec.

**TWEKESBURY.** July 25th. Mr. P. Moore and Mr. H. J. Cochrane, Hon. Secs.

**WREXHAM.** July 25th. Mr. J. B. Shirley, Hon. Sec.

**HUNTINGDON.** July 28th. Mr. J. Dille, Market Place, Sec.

**HEADINGLEY.** July 26th and 27th. Mr. T. Atkinson, Burleywood, Headingley, Leeds, Sec.

**ABERDEEN (Royal Horticultural Society).** July 26th, 27th, and 28th. Mr. Archibald J. Rennie, 123, Union Street.

**BRIGHTON.** July 29th. Messrs. C. Jessop & E. Bawnley, Hon. Secs.

**SALTAIRE.** July 29th. Mr. G. A. White, Hon. Sec.

**KILBY (Flowers).** August 1st. Mr. C. E. Bracebridge, Sec.

**HEWORTH (Horticultural).** August 2nd. Mr. B. H. Felton, Hon. Sec.

**BAWENSTALL (ROSEDALE).** August 4th and 5th. Mr. M. J. Lonsdale, Sec.

**SOUTHAMPTON.** August 5th and 7th. Mr. C. S. Fudge, 89, York Street, Sec.

**FINEDON.** August 7th. Mr. G. C. Mann, Sec.

**TAUNTON DEANE.** August 10th. Mr. F. H. Woodforde, M.D., and Mr. Clement Smith, Hon. Secs.

**FILEY.** August 11th. Mr. Walter Fisher, Hon. Sec.

**OTLEY.** August 12th. Mr. Alfred Suttle, Hon. Sec.

**CLAY CROSS.** August 15th. Mr. J. Stallard, Clay Cross, near Chesterfield, Sec.

**WESTON-SUPER-MARE.** August 15th and 16th. Mr. W. B. Frampton, Sec.

**FRESTON.** August 16th and 17th. Mr. W. Troughton, Hon. Sec.

**SHREWSBURY.** August 16th and 17th. Admitt & Naunton, Hon. Secs.

**LEDBURY.** August 17th. Mr. J. B. Masfield, Hon. Sec.

**NORTON, NEAR STOCKTON-ON-TEES.** August 18th. Mr. C. Turner, Sec.

**MIRFIELD.** August 19th. Mr. G. Senior and Mr. J. Rushforth, Hon. Secs.

**CALNE (Wilts).** August 22nd. Mr. H. Blackford, Sec.

**NEWBURY.** August 22nd. Mr. H. Seymour, Hon. Sec.

**DORSET COUNTY.** August 23rd (at Dorchester).] Mr. A. Pope and Mr. C. Parsons, Secs.

**CHESTER.** August 23rd. Mr. B. Thorn, Hon. Sec.

**CARSHALTON, WALLINGTON, AND BEDDINGTON.** August 24th. Mr. J. Baines, Leicester House, Carshalton, and Mr. W. Clark, the Nurseries, Wallington, Hon. Secs.

**SEATON BURN.** August 26th. Mr. B. Richardson and Mr. W. Elliott, Secs.

**ISLE OF THANET (MARGATE).** August 30th. Mr. C. D. Smith, 8, Marine Terrace, Margate, Sec.

**POCKLINGTON.** August 31st. Sec., Mr. J. E. Ross.

**MONTROSE.** September 1st and 2nd. Mr. Alex. Burnett, 2, High Street, Sec.

**DUNDEE (International).** September 7th, 8th, and 9th. Mr. W. R. McKelvie, 26, Euclid Crescent, Sec.

**GLASGOW.** September 12th and 13th. Mr. F. Gilb. Doughall, 167, Canning Street, Sec.

**ROYAL CALEDONIAN HORTICULTURAL SOCIETY.** September 18th.

**IPSWICH.** September 17th. Sec., Mr. W. B. Jeffries, Henley Road, Ipswich.

**NORTHAMPTON (Chrysanthemums).** November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

**PADLEY'S PIPPIN (T. Hall).**—It is thus described in Dr. Hogg's "Fruit Manual":—"Padley's Pippin (Padley's Royal George Pippin).—Fruit small, 2 inches wide and 1½ high; roundish-oblate. Skin pale greenish yellow, rather thickly covered with thin grey russet, and faintly tinged with orange next the sun. Eye small and closed, set in a shallow and rather angular basin. Stalk three-quarters of an inch long, slender, and inserted in a rather shallow cavity. Flesh yellow, juicy, sugary, brisk, and richly aromatic. A dessert Apple of first-rate quality; in use during December and January. The tree is of small dimensions, but healthy and a prolific bearer. It is well adapted for dwarf training when grown on the Paradise or Doucin stock. This variety was raised by Mr. Padley, gardener to His Majesty George III. at Hampton Court. According to Rogers, Mr. Padley was a native of Yorkshire, and after coming to London and filling a situation of respectability he was appointed foreman in the kitchen garden at Kew. "On the death of the celebrated 'Capability Brown,' Mr. G. Haverfield was removed from Kew to Hampton Court, and took Mr. Padley with him as foreman. On the death of Haverfield Padley's interest with his Sovereign outweighed all the interests of other candidates, though urged by the most influential persons about Court. 'No, no, no,' said His Majesty, 'it is Padley's birthright.'" We believe it can be purchased at the nursery you name.

**EARLY SECOND PEA.**—Mr. Warren, the Earl of Portsmouth's gardener, highly commends Carter's Commander-in-Chief.

**SECOND-HAND BOOKS (F. H. T. E.).**—You had better put them into a sale near you. Imperfect works are not saleable to a London bookseller.

**HOLLYHOCK LEAVES DISEASED (M. Cross).**—It is a fungus, not an insect, which is scourging the leaves. Pick the leaves off and burn them, and dust the plants with flowers of sulphur.

**EXCLUDING SNAILS.**—W. G. says a ridge of quicklime along the top of the wall will prevent the snails passing. A horsehair rope stretched along the top of the wall would be a barrier.

**SEEDLING GLOXINIAS (E. C. B.).**—They are good, especially 1 and 5. The other blooms were damaged; 4 is good if the corolla is not flimsy.

**VINES FAILING (J. L.).**—Not sufficient ventilation and want of watering are the causes. You opened the windows after the mischief had occurred.

**PEACH LEAVES BROWNED (J. McMurray).**—Deficient supply of sap is the cause, probably from the roots not being sufficiently and regularly watered.

**PLANTAINS ON LAWN (C. M.).**—There is no mode of destroying them so cheap or effectual as cutting them out with a knife. We call it "the-old-woman-and-old-knife remedy."

**CANTERBURY BELLS (P. P.).**—Plant these a foot apart in order to obtain fine spikes of bloom; the other flowers you name half that distance.

**IMPREGNATING MELONS (D. E. F.).**—This is done by rubbing the dry pollen taken from the male flower upon the stigma of the fruit or female flower, an operation that is considered necessary only for very early crops. At this season of the year under good culture and a free system of ventilation artificial impregnation is unnecessary. Due attention to providing suitable soil, thinning, stopping, watering, and ventilation usually leads to success. This formula rules our practice, and we are now cutting plenty of good fruit.

**FERN CULTURE (H. W. G.).**—You will find directions and descriptions in our "Fern Manual."

**GERARD'S CATALOGUE (J. H. R.).**—Mr. Jackson has not published it. He might lend you a copy.

**PLUM STOCKS FOR PEACH TREES (An Amateur).**—The Brompton and Muscote Plum stocks are used for grafting or budding upon. Any respectable nurseryman can supply them. We have found the common Bullace, which is propagated by suckers, a good stock.

**MELON LEAF (Constant Reader).**—We fail to notice any insects or trace of them having infested the leaf enclosed. There are traces of sulphur, which is perfectly innocuous, on the dried leaf, probably due to extravaesated sap, the stem being dead; or it may arise from damp at the collar of the plant.

**ANNUALS FOR SPRING BEDDING (J. A. S.).**—The best are the Silenes pendula and vars. alba, compacta, compacta alba, ruberrima; Laesthia californica, and Collinsia verna, which should be sown about the second week in August, also at the same time Veronica syriaca. Others to be sown the early part of September are—Collinsia bicolor, C. candidissima, and C. grandiflora; Nemophila insignis, N. insignis alba, N. atomaria; Limnanthes Douglasii, L. grandiflora; Saponaria calabrica, S. calabrica alba; Campanula pentagonia and var. alba, Venus's Looking-glass, blue and white vars. Candytufts and Clarkias are also useful, with Larkspurs sown at the same time.

**OAK TREE BLEEDING (Henry Seymour).**—The bleeding will shortly cease of itself, and no untoward consequences will result beyond a scar. You may, however, fill the opening or hole with cement, and over this the bark will in time grow, the cement not coming out further than the wood, and fill-up level with the bark with the patent knotting used by painters, which will partially if not wholly check the bleeding.

**COCCUS CAMELLIE (S. C. A.).**—If it recurs repeat the application. Whether it would live on the Vine we do not know, but do not think it would, but it would on Azaleas.

**STOVE FOR CONSERVATORY (Sol).**—Select one from our advertisement columns, but have a tube flue to convey the fumes of the fuel into the outer air.

**DESTROYING FUNGI ON A LAWN (Nimrod).**—We do not know of any method of destroying fungi without doing injury to the grass. The spawn is, of course, the primary source of your annoyance, and as that spreads more freely near the surface among the roots of the grass than elsewhere during the season of growth, the only remedy is to remove the whole of the affected turf and soil, replacing it with some other that is free from the pest, or to dig up the lawn, burning every particle of soil and turf which contains the thread-like spawn, and then levelling it down again, and either sow grass seed or re turf it.

**NAMES OF PLANTS (F. W.).**—The specimens are not numbered, so cannot be referred to. (*Mac.*)—*Spiraea arifolia*. (*A. Reader*).—*Muscari comosum*, var. *monstrosum*. (*E. E.*)—1, *Collomia grandiflora*; 2, *Lapsana communis*. (*J. F.*)—1, *Carex paludosa*; 2, *C. distans*, var.; 3, *C. ovalis*; 4, *C. palescens*; 5, *C. distans*; 6, *C. pendula*. (*R. F. B.*)—*Mitrisia coccinea*. (*Mrs. H.*)—1, *Iris pumila*; 4, *Sedum album* or an ally; 5, Looks like a *Phlox*, but too withered. (*L. M.*)—6, *Asperula arcadensis*; 7, *Hieracium aurantiacum*; 8, *Lotus corniculatus*. Specimens of Ferns insufficient. (*A. Boyle*).—1, *A. Sedum* (perhaps *S. Sieboldii*), not a Saxifrage; 2, *Astibe barbata*, often mis-called *Spiraea japonica*. (*E. H. B.*)—A double Larkspur, species indeterminate.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### DISQUALIFICATIONS.

We have before us the schedule of the Warminster Cottagers' Garden Society, and we read among the rules of the poultry department—"The Judge will be instructed to disqualify any pens, &c. In this case the cause of disqualification will be posted on the pen and in the prize list." We consider this rule admirable, and would recommend its being inserted in all schedules. The word disqualification is itself so ugly, and carries with itself so much that is unpleasant, that we consider, in justice to exhibitor and judge, the cause of the disqualification should always be made known. In many cases a bird is entered in a wrong class, and the pen is consequently "disqualified;" but a bird with plucked hocks, false tail, dyed legs, or cut wings is also "disqualified" when the case is detected. Visitors at shows, however, and distant exhibitors are very often quite unable to know whether a bird they see with a disqualified ticket is so disgraced from a mistake in making the entry, or for being doctored dishonestly to secure a prize. We feel that a bird which is wrongly entered, or a young bird which is entered in an old class, or any case which shows the mistake could only have arisen from a blunder and not from desire of deception, should not be disqualified at all, but should be ticketed "entered in the wrong class," or with some such label on the pen and in the catalogue, and the word disqualified would then, if only used for cases of trimming and such like, at once imply something really wrong. It is a most difficult matter to know where trimming and doctoring legitimately begins and ends in these

days, that is if it ever ought to begin at all; but though we do not in any way want to go into what is lawful and what is not, or whether any beautifying process is legitimate, still we must say we experience difficulty to find just where the judges do draw their line. Everyone knows that no Game, Spanish, or White-crested Black Poland is put into a pen by an exhibitor of any understanding without being trimmed somewhere on the head; or again, that any of the knowing north-country Ham-burgh breeders exhibit their birds without the comb being carved and cut into order, consequently while these things are allowed by the judges we cannot imagine on what principle they regulate their ideas about when a bird is overtrimmed. As we said, we do not mean to say whether we think trimming and beautifying is advantageous or not, but we do want to know why it is worse to cut a Spanish cock's comb than it is a Ham-burgh's; why, in fact, should a Spanish cock with a cut comb be passed over, which really means disqualification, while at the same show a Ham-burgh with a manifestly home-made pike to its comb may have first prize? why, again, a Spanish cock or hen with a face which must have been touched-up should win a prize, while a chicken which also has been touched-up should be disqualified? At Abingdon last week we heard several wonder why no second prize had been awarded in the Spanish, and we were told the birds which were to have had that honour were too much trimmed, and so the pen was disqualified. We should like to know if the judge thought the first-prize pen was shown just as Nature had made them.

We often think many of the birds which deserve disqualification come off scot-free, although the adjudicators knew full well the birds deserve the ugly card, while on other occasions some birds are disqualified which do not deserve it. Everyone remembers the case of a well-known hooked Brahma hen being disqualified because the tips of her hocks had been rubbed off, and everyone who knows anything about poultry would know that a hooked hen to be trimmed would not have been dressed in that rude way, but would have had the feathers abstracted and the holes cauterised to prevent their growing again, or they would have been cut off close to the skin so as to avoid detection. The bird had evidently been running on rough ground, and the hocks had lost the tips of their feathers by the friction; and yet here was a bird disqualified and a yard disgraced because more trouble had not been taken to ascertain whether any other cause was possible beyond the fact of trimming. And then another case, when a Cochins cock, which was a notorious winner, had at the end of a long season of many triumphs broken his tail feathers from the frequent penning, was disqualified. No one could imagine why, for the bird was almost as well known as the judge himself; and even had this adjudicator thought it best to disqualify him for the broken feathers, although he knew the bird desired no doctoring at all, it would have been more satisfactory for him to have stated the reason of the bird's disgrace. We feel it is most important that the cause should always be known, and as this to a great extent lies with the judges, we hope that they will write their reasons on their slips and ask the secretary to have the same posted and recorded as much as if they had won the cup or first prize.

We feel the subject wants to be aired, for we have heard of more disqualifications in the last few weeks than ever before, we think, in as many months. Over and over again we hear of a whole class of Nuns being disqualified, but we never remember hearing before of a whole class of Spanish being ticketed with the same objectionable cards for being "overtrimmed" as we have done this week. We can only say that we really should seriously recommend Spanish exhibitors to find out from the judges what they will allow and what they will not, for the very fact of the birds being called "overtrimmed," as our correspondent who wrote to us termed it, shows that it is generally supposed that the judges will bear with a certain amount. But when the bounds are stepped over and the judge feels that he must disqualify, by all means let those at the show and those away from it know the cause of the disqualification, or else a pair of Brahmas entered by mistake among the French may to the uninitiated and the absent appear to be in the same boat with a notoriously dyed Duckwing or clipped Golden-spangled Ham-burgh.—W.

#### RIPON SHOW OF POULTRY, &c.

THE annual Show was held at Ripon on the 4th. The pens were fixed in the open field; but the day being fine and the pens being placed under some large trees all passed off well. The prize list was but small, and for the amount offered the entries were good.

Game headed the list, and these were in pairs, and a mixed class; the first Brown Reds, and second Duckwings, both very good and well placed. Spanish and Brahmas very poor; but Dorkings good. In Cochins first were Buff, the cock a grand colour but a little bad on feet; second Black. Among the Ham-burghs were some very good birds, especially the Gold-spangles and Silver-pencils. Bantams poor, except the winners in each class. Turkeys a grand class, very even, and the

whole of them noticed. Ducks a failure; but Geese and Guinea Fowls really first-rate. In the former White Embden won both prizes.

In Pigeons an old trick was played. One large exhibitor with entries in every class never turned up, no doubt some crotchets or other having deterred him; but in this case there is little doubt but that the fine to be imposed in each case of failure to exhibit would be enforced, and thus Mr. Horner will be taught to respect the provision made for him in future. The entries were pretty good, and in some classes the birds were very good. Pouters, Almonds, and English Owls, especially the latter, being very good indeed.

Rabbits were badly classified, and the consequence was the stock shown was poor except the first, which was a nice Himalayan.

POULTRY.—GAME.—1, W. Bearpark. 2, W. Scott. SPANISH.—1, Horner and Holdsworth. 2, H. A. Hawkins. DOCKS.—1, T. F. Carver. BRAHMA FOOTBALL.—Light.—1, H. Digby. 2, J. Smith. Dark.—1, G. Mangles. JUDGE.—Mr. Cannan.

#### HANTS AND BERKS AGRICULTURAL SOCIETY'S SHOW OF POULTRY, &c.—ABINGDON.

THE progress of this deserving Association is truly remarkable. A few years since it was open for a few hours of one day at a small Hampshire market town, now it covers several acres. Its entries count by hundreds, and its visitors by tens of thousands. It is a busy scene. We suppose it arises from the fact that everybody at an exhibition is more or less on the loose, or that paterfamilias when he goes home is expected to take something for everybody from mater downwards, or that the many couples that tell themselves off are looking forward and either buy or promise to buy; but it is a fact, some parts of the stalls remind one of a continental fair. Such receipts for mending china—a willow-pattern plate broken across and mended with this cement continues entire, although it is suspended at top through two holes by a strong cord, and the lower half is tied by a half-hundred weight hanging to it. One most persevering individual wished to borrow everybody's knife that he might rub it on a poker, and then restore the sharp edge by the use of a steel of his own. Every sort of cart and carriage. Gates that even a donkey cannot open. Portable-folded seats, handy to carry, very light, and most comfortable when in use. Such dairy appliances—we must call them beautiful. Such churns, invaluable if they will do half that which they are warranted to do. Garden seats and flower pots in every material. Whatever the cause may be, school of design or otherwise, no one can deny or be blind to the wonderful improvements in the designs of these beautiful manufactures. Pumps of every description. Steam engines crushing stones, throwing water, digging holes, hoisting straw, and obedient as any slave of the lamp. Sewing machines of every sort. Children's useful toys, such as gardening tools, wheelbarrows, and perambulators. Giant seed establishments boasting every decoration. The English are a sporting people. How they run to the announcement, "The horses are going to the ring," and how they enjoy the riding round and the jumping. Then the two military bands discoursing sweet sounds at different places; and then the ring in which the dogs are judged, most competitors in the hands of their owners. The dear pug that will not leave its mistress, and seems aware he has got into mixed company.

The good old town—and there is no doubt of its antiquity—was en fête. The streets lined with lofty masts covered with striped calico, and bearing banderolles and flags. Ropes spanning the streets, from which were suspended all the colours we have seen for years. We almost fancy that like Albert Smith's sponge-cake elephant at the supper, we recognise some of the decorations, having seen them at many. If good wishes are worth anything "Agriculture" should do well. She had "Welcome" in all directions, and it seemed the universal wish that she should have "success" and "prosperity." We have been to many towns in our lives, but never before to one of this magnitude.

where there was no conveyance of any kind. When we left the train we found "led dogs," "baskets of poultry," and men and boys. We asked for a conveyance, and they stared us an answer. "Martha Muggins's donkey cart" would have been a luxury. It is not desirable to have to carry even the small "impedimenta" necessary at this time of year. We were painfully reminded of the fact, when a small boy read our thoughts and offered to carry the small trunk and to show the way. We reached food and bed in safety, and early the following morning visited the poultry.

The *Dorkings* were very good, but we doubt the wisdom of having a Silver-Gray class. We would give the amount of the six prizes to an open class of the breed. The *Buff Cochins* had some good specimens, but many of them were hideously vulture-hocked. The same may be said of the *White*. The same appendage prevailed among the *Brahmas*, which were otherwise good birds. These vulture hocks are a disputed point. They are of recent introduction. The institution of shows was for the improvement of domestic poultry. No one can say the vulture hock is an improvement. Domestic poultry is for the table, it was intended to supply markets with better food. Vulture hocks increase trouble in preparing for market, and can have no beneficial effect on the flesh or growth. The *Spanish* were good, but the best pen in the class, No. 43, was disqualified on account of flagrant and unwise trimming. The *Game* were excellent in both classes, and here another question will arise. To the present time an undubbed cock was disqualified, but now they increase in numbers. There were very good *Hamburghs* shown in all the classes, the prizetakers deserved their honours. They were good birds, both *Spangled* and *Pencilled*. The *Pencilled* hen in 73 was perfect. *Polands* were good but not numerous. We advise that next year there should be one class for *French* fowls, and that the six prizes should be of the same value, but made into four instead of six. There were good *Houdans*, and an excellent pen of *Crève-Cœurs*. *Game Bantams* showed well, but the question of dubbing suggested itself again, undubbed birds show at a great disadvantage. Our old favourites the *Sebrights* can hardly hold their own. The Variety class brought *Black Hamburghs*, *Dumplings*, *Malays*, *Silkie*s, &c., and many excellent specimens. The *Rouen Ducks* were good, but it is hard to decide between young and old at this time of year. The *Aylesbury Ducks*, *Geese*, and *Turkeys* were all good, especially the two latter. They were shown in capital feather and were very heavy.

*Pigeons* formed no mean part of the Show, beginning with *Pouters*, then an excellent entry of *Carriers* and *Jacobins*; small numbers of *Fantails*, but very good, having tails of thirty and thirty-three feathers; a great show of good *Turbits*, and fourteen entries of *Dragoons*—nine of them figured in the prize list, fifteen entries of *Magpies*, ten of *Antwerps*, twelve of varieties, and twenty-two of homing *Pigeons*.

*Lop-eared Rabbits* measured none less than 19, but some reach 20 inches. The *Hare Rabbits* were few, but two of them, the prizetakers, were as good as we ever saw. There were thirteen entries in the *Various* class. The *Silver-Grays* were the best, but there were also very good *Himalayans*.

The weather was favourable, and it was a holiday week for all but the Committee, who, headed by the ubiquitous Mr. Downes, were wherever their presence was required.

**POULTRY.—DORKINGS.**—Coloured.—1, T. C. Burnell. 2, Mrs. Allsopp. 3, Mrs. M. D. Dunn. *Other varieties*.—1, S. Salter. 2, T. C. Burnell. 3, J. Calcutt. **COCHINS.**—*Buff*.—1, T. C. **JUDGE.**—Mr. John Bailly, Mount Street Grosvenor Square, London.

## POULTRY AND BEE NEWS AND QUERIES.

UNDER the general name of "poultry" there have been sold at Paris in the course of 1875, 5,656,779 chickens, 2,156,610 tame Rabbits, 1,583,317 Pigeons, 706,389 Geese, 695,648 Ducks, 479,816

Turkeys, 126,539 kids, 23,660 lambs and sucking-pigs, 14,956 guinea fowls, 21,014 kilogrammes (about 22 tons) of Goose livers, 11,617 kilogrammes (about 11 tons) of cocks' combs, 9,308 kilogrammes (nearly 10 tons) of Ducks' livers, and 121 kilogrammes (more than 2 cwt.) of chickens' kidneys. Altogether, the game and poultry sold during the year represented a weight of 21,064,569 kilogrammes (more than 21,000 tons), which is equivalent to an annual consumption of about 25 lbs. for each of the 1,851,000 inhabitants of Paris.—(*Fall Mall Gazette*.)

## OUNDLE SHOW OF POULTRY, &c.

This pleasant little annual gathering was held on the 5th inst. The quality was very good, and the awards gave great satisfaction.

In *Dorkings* the chickens of Mr. Burnell were forward and good; we were surprised to see them in for so low a figure. The *Black Reds* were very good in *Game*, the first being a very stylish and good bird. A very promising pair of *Black Red* pullets were shown, which took first; the second were younger, but also good. *Spanish* were good, and we are glad to see this old variety looking up more of late. The *Spanish* chickens were all disqualified for being overdressed. *Cochins* brought some very good entries; a rare *Black cock* was first, as good a bird as we remember to have seen this year. In hens a good *Partridge* was first, a nice *White* second, and a fair *Buff* third. In chickens the first were very forward and matured-looking *Buffs*; a nice pen of *Whites* being third. In *Brahmas* we liked the winners very much; the first cock is stylish, and with his style is deep and massive. The first *Light* hen is a grand hen, and we think will be a bad one to beat. *Light Brahma* chickens were forward and good; but we sometimes really think *Brahmas* have nearly seen their day, and will have to give way to *Cochins* or *Dorkings* once more for being the popular variety. The Variety class contained a grand pair of *White-crested Polands*; the hen a gem, and the cock, though yellow in crest, from the sun we suppose, is a large bird, and carries himself well. *Ducks* were few and good; a nice pair of *Rouen* ducklings won first in their class. A capital pen of *Turkeys* won; second going to a nice pair also, but not so large as the winners. In the *Sale* class a good *Buff* cock was first, while in hens a capital *Partridge* took premier honours, and deserved them—cheap at catalogue price. We wonder why the cock was not to exceed 30s. in price, while the hen might be valued at 40s. *Bantams* were numerous; we believe *Brown Reds* and *Silver-laced* took equal firsts.

**POULTRY.—DORKINGS.**—*Cock*.—1, E. Snell. 2, Countess of Dartmouth. 3, Rev. F. R. Smythe. *Cockers*.—1, T. E. Burnell. 2, L. B. Calcutt. *Hen*.—1, H. Feast. 2, E. Snell. 3, Rev. F. R. Smythe. **PULLETS.**—1, T. E. Burnell. 2, L. B. Calcutt. **GAME.**—*Cock*.—1 and 2, Mrs. S. Deacon. 3, H. Lotan. *Hen*.—1 and 3, Mrs. Deacon. 2, H. Lotan. **PULLETS.**—1, E. Winwood. 2, S. Tilley. **SPANISH.**—*Black.*—*Cock*.—1, J. T. Parker. 2, D. M. Mills. *Hen*.—1, E. Winwood. 2, W. Nottage. 3, J. T. Parker. **COCHIN-CHINAS.**—*Cock*.—1, E. Snell. 2, H. Tomlinson. *Hen*.—1, 2, and 3, Mrs. A. Tindall. **CHICKENS.**—1, J. M. Skarratt. 2 and 3, Mrs. A. Tindall. **BRAHMAS.**—*Dark.*—*Cock*.—1, J. F. Smith. 2, W. Whitey. *Hen*.—1, J. F. Smith. 2, H. Yardley. **CHICKENS.**—1, E. Pritchard. 2, J. S. Clarke. **LIGHT.**—*Cock*.—1, Mrs. Peete. 2, Mrs. A. Tindall. *Hen*.—1, Countess of Dartmouth. 3, P. Haines. **CHICKENS.**—1 and 2, G. Breeze. **HAMBURGHS.**—*Gold and Silver-pencilled*.—1, W. K. Tickner. 2, H. Pickles. *Gold and Silver-spangled*.—1, H. Feast. 2, H. Pickles. *who*.—W. S. Evans. **BANTAMS.**—1, Mrs. Deacon. M. Leno. *who*.—H. Robinson. *ANY OTHER DISTINCT BREED.*—1, T. Norwood. 2, H. Pickles. 3, A. Biggs. *who*.—Mrs. A. Tindall. *H. Feast*. E. Snell. **SELLING CLASSES.**—*Cock*.—1, M. Leno. 2, Mrs. A. Yardley. 2 and *who*. M. Leno. **TURKEYS.**—1, Countess of Dartmouth. 2, E. Snell.

## HONEY SEASON NEAR LINCOLN.

THERE is abundance of flowers about here this spring, but the weather has been so cold until recently that the bees could not get out to gather the honey. I have had my hives well covered, but the bees were very late before they would take syrup down from the bottle, and I was doubtful if I should raise a swarm.

Referring to my diary I find the following entries:—Hive No. 1, 18th November, 1875, weight without hive and board 27 lbs., covered up for the winter; 1st March, 1876, first pollen carried in; 11th March, weight 21 lbs. Very little done till the last of the month and the beginning of April. On April 3rd I cut out some mouldy comb. Up to the 29th I had given 1 lb. of sugar; the weight was reduced to 18 lbs. By May 23rd it had gained 2 lbs.; I gave 1 lb. more of sugar, and I saw one drone out on the 21st. I intended to take an artificial swarm on the 30th, the hive was so full, but the weather had been so cold—28th. I went to look at my bees at 10 a.m., and I had a fine swarm on a currant tree close by; I hurried back for my hive, I could not put it over the bees and they had broke the branch down on the ground, so I put most of them in with my hand, and placed the hive by the side of them. I had them on their proper stand within fifteen minutes. It is a 16-inch hive, 13 inches deep; the largest I could procure about here.

May 29th 14 lbs. weight after swarming, so I had about a 6-lb. swarm. I never saw a hive left so empty of bees after a swarm before. If I had taken an artificial swarm I dare not have taken so many out. For three or four days there were very few bees about, and then they began to pull out the brood, so I fed a

little. June 9th they weighed 19½ lbs; bees began to increase in numbers; June 12th, so full of bees that I put on a four-bar-frame super, 6 inches square inside measure, and they took to it at once. On the 16th I put an eke under in the morning, and took off the super at noon with three bars partly full of comb, and some honey. At night I drove out the bees, and took 15 lbs. of honey. It is all spoke for at 1s. per pound. I transferred the bees into a 16-inch square (10½ inches deep inside measure) ten-bar-frame hive, bars 1 inch wide, with the outside bars a little wider, three holes at top for supers and two for feeding. I tied what little comb in the bars I could get with very little brood in. In putting the bees in I was stung once. June 28th, a good swarm placed in the place of the old stock, 16 inches wide, 13 inches deep, weight 8½ lbs., weight of board 7 lbs.; June 12th, weight of hive, &c., 33½ lbs.; June 20th, weight of hive, &c., 45 lbs.; 22nd, a queen bee out dead, it may have come from No. 2 hive close by, as they were piping for the third swarm.

Hive No. 2, sugar-fed bees that I saved from the sulphur pit, November 1st, 1875, three young bees out dead (white ones), weight of hive, bees, &c., and a 7-lb. floor board, 25 lbs.; covered up for the winter, the hive about half full of comb, a large hive for this part of the country. March 1st, 1876, weight of hive, &c., 22 lbs., received 1 lb. of sugar, and to May 8th 3 lbs. more sugar, and they began to build comb; weight of hive, &c., 21 lbs. 23rd, two more pounds of sugar; weight, &c., 23 lbs. I gave 1 lb. more sugar on the 9th of June; weight of hive, &c., 35 lbs., and quite full of bees. I took an artificial swarm out at night of 5 lbs., both stock hive and swarm doing well. June 12th the stock had increased to 33 lbs. again; June 16th began to pipe, so I was only just in time to take an artificial swarm; 19th a false swarm. The queen was the last out of the hive; I caught her, took her 10 yards off, but she escaped from me, and I was just back to see her go in the hive; all the bees returned in a few minutes; a good cast next day, 9.5 A.M.; weight before 37 lbs. At night I cut a queen cell out, but let her escape into the hive. They are still piping up to-day (June 23rd), but it pours with rain.—J. M.

### OUR LETTER BOX.

**PRESERVING EGGS (G. Brown; J. Winnip).**—Put them in layers alternately with common salt in a box, and keep in a cold dry place.

**ADDING BEES TO SWARMS (R. S.).**—Do not turn out your bees now from the old skeps unless you join them the one to the other. You might do this with advantage, making a fair stock of one of them; but you might seriously interfere with the success of the swarms by attempting to increase their population by adding the bees of the old skeps to them now. This is better done in September. Remember that the comb in swarms is very soft and delicate, and any movement of them might bring the whole mass down and ruin the hive.

**WEAK HIVES, CROSS STICKS, &c. (F. J.).**—Very weak hives can be safely treated as "B. & W." suggests; also you can bring the old hive back to a place pretty near the old place. But twenty-four hours is too short a time; twice or thrice that time would be better. If you move the hives apart in the first instance 30 yards it will do, but hide as much as you can. It is not of much importance what the width of the bars is provided you measure 1 inch and 7-16th from centre to centre of each frame, but you may allow one-fourth or three-eighths of an inch between each bar. Box hives 16 to 18 inches square should certainly have cross sticks if over 10 inches in depth; but we would put them near the base of the hive so as to be easily removable—say 1 inch from the bottom. Wire will not do. It is a pity you did not put a cross piece of wood with guide comb in your glasses.

**PRESERVING NATURAL HISTORY SPECIMENS (Agnes).**—A book exactly suited to your need is "Notes on Collecting and Preserving Natural History Objects." It is published by Messrs. Hardwicke & Bogue, and includes zoology, botany, and geology.

**TAMING A YOUNG FOX (M. E. P.).**—We have kept foxes in our time and had them perfectly tame. We always chained them to a very large tree, and they made a kennel under the roots. Where that cannot be they must have a kennel something like a dog's, but they are never so sweet as when they lie on earth. They should have a long chain, and the amount of liberty may be very much increased by having at the end of the chain a ring running on an iron rod fixed in the ground by an upright at each end. It helps to tame everything to keep it well fed. The best food is the offal of poultry, or Rabbits, or Pigeons. Any kind of meat will do if these are missing. You should not feed till the fox comes for the food, but this should not be the result of starvation, but of liking. Never put the food where you cannot see it taken, and you always have the means of correction by withholding food.

**ARTIFICIAL SWARMING (Rev. S. A. Brennan).**—You did well to swarm your bees on the 19th of June, but on discovering foul brood in the old hive shortly afterwards you should not have turned all the bees out of it on the 26th of June. You should have waited till the 7th of July, for then the brood would have been hatched and a young queen reared. If the old hive had not a queen in the cell eight days old at the time you took your artificial swarm, your turn-out or second swarm is now without a queen. The queen of a hive goes with the first swarm, and it takes fourteen days to rear another from the egg to perfection. If your second swarm is working satisfactorily and building worker comb you may conclude that it has a queen which was hatched within eight days of the time of swarming. The time to super hives is when they become full of combs and bees. Neither of your swarms will fill their hives for a month.

**FEEDING BEES—WEIGHT OF STOCK (Jane).**—Either your muslin or your syrup has been too thin. In feeding bees from the top with a bottle a piece of cotton cloth is tied over its mouth before it is inverted, and placed over the aperture. Or better still, a piece of perforated vulcanite (made and sold for the purpose of feeding) is placed over the aperture, and the bottle is placed

inverted on it. Many bee-keepers like top-feeding, and find the bottle and vulcanite answer very well. An 18-inch stock hive with a good population should weigh about 40 lbs. in September to be safe for the winter and early spring months. Stocks of this kind consume about 15 lbs. each of food from September to March. In open winters bees fly much about, and therefore consume more than they do in cold and stormy winters.

**BEES CLUSTERING OUTSIDE HIVES (J. D., Leeds.).**—We consider that to let bees cluster outside a hive and in large masses below the board in July is not good for either the bee-master or the bees, and when this clustering is permitted to go on for weeks a great loss is sustained.

**ZEBRA GRASS PARAKEETS AND GRASS SEEDS (G. H. P.).**—In a state of natural freedom on the plains of South Australia, Zebra Grass Parakeets live almost entirely on the ground feeding on the seeds of grasses. In answer to your question "whether grass seeds may be given and what kinds?" we reply by stating that you should select the smaller sorts in preference to others, some of which are so coarse as to be suitable only for cattle. We could name upwards of thirty kinds of grass seeds, among which are those known as the vernal, bent, panic, galangale, sedge, feather, hair, rope, reed, meadow, dogstail, foxtail, catstail, cocksfoot, couch (known as squitch or twitch), and many others, amongst which canary and millet are considered as two kinds in the genera of grasses. But it would be unwise to give the Parakeets indiscriminately any coarse kinds of grass seeds. In their native climate no doubt they have many varieties to choose from, and their instinct may lead them to be somewhat epicurean in their appetites. We cannot inform you what kinds of grass seeds they prefer. Our experience has convinced us that Zebra Parakeets can enjoy good health on a canary and millet seed diet.

### REMARKS.

- 5th.—Cloudy all day; a slight gleam of sun in middle, and slight shower about 10 P.M.  
6th.—Cloudy, with occasional sunshine; rain at night.  
7th.—Fine morning, but rather dull after, especially about 5 P.M.  
8th.—Dull morning and early afternoon, shower at mid-day; fine evening and night.  
9th.—Dull morning, fine afternoon and evening, though the latter was rather cool.  
10th.—Fine bright fresh day throughout; cold at night, in fact the coldest during the week.  
11th.—Another comparatively cool day, but very pleasant, though rather overcast and rain-like at times, and even cooler than yesterday.  
A fine warm week; westerly wind, but very little rain.—G. J. SYMONS.

### COVENT GARDEN MARKET.—JULY 12.

Prices remain the same; a fair supply and moderate demand.

From observations taken near London during forty-three years, the average day temperature of the week is 74.8°; and its night temperature 57.8°.

## RHODODENDRONS AT DUNEEVAN.

NOT more famed is the beautiful garden of Mr. McIntosh for the unequalled display of *Lilium auratum* in summer and autumn than for the choice and extensive collection of Rhododendrons, which produce a spectacle of gorgeousness in the earlier days of spring. These two plants—*Liliums* and Rhododendrons—are associated together and are grown by hundreds, if not by thousands, each receiving the best cultural care, and each in their seasons producing an effect which no other plants can equal.

Duneevan was visited last year when the *Liliums* were in beauty, and notes of them may be found on page 295, vol. xxix.; it was visited again this year when the Rhododendrons were in their splendour, and a few notes of that visit may fittingly have a place in your pages. To adequately describe the effect of the glowing masses is impossible, as by the pencil it would be futile; it may nevertheless be useful to append a few remarks, seeing that a selection of the best varieties chosen from a collection so extensive and so rich cannot fail to be reliable as comprising some of the very best and most effective varieties of the day. The notes, therefore, taken at flowering time may be preserved for planting time, and those who add the varieties to their collections may plant in confidence that they will have "something good."

The general effect of the Rhododendron beds is heightened by their position. These beds are on an irregular lawn, and which also contains many perfect specimens of choice Conifers. Mr. McIntosh's garden has, like the Crystal Palace, "high level" and "low level" stations. The Rhododendrons are on the low level, and viewing them from above—that is, from the brow of the bold natural terrace, the effect when in bloom is magnificent. They are arranged with the greatest care as to the mixing of their colours, so that the whites, pinks, purples, and crimsons show to the greatest advantage. The work of planting and arranging the plants tastefully is an annual task of no small magnitude. Each year the newest varieties are added, and each year older and commoner sorts are removed, and a general redistribution necessarily follows.

In order to expedite planting correctly a simple but very effectual expedient is adopted by Mr. McIntosh. Previous to removal and planting every plant is "coloured"—that is, the colour of its flowers is shown by a shred of some textile fabric, which is tied on a topmost branch. It is easy to perceive the value of this simple plan when large numbers of plants must be removed and planted in different positions in a garden. Much time is saved in searching for and reading the labels, and mistakes in planting are reduced to a minimum.

In this great collection every plant has its name and colour plainly written by Mr. McIntosh on a zinc label; but so practically acquainted is the owner with his plants that almost every variety is known to him without re-

ference to the tallies: the correct naming of the plants, however, adds much to the value of the collection, and renders it additionally enjoyable and instructive to the many visitors who have not a particular acquaintance with the several varieties. Besides the plants in the beds there are fine standard specimens on the lawn, than which few objects are more ornamental. A trio of these standards—*Scipio*, *Archimedes*, and *John Waterer*, were extremely effective, the last-named having last year 114 glowing trusses expanded. Other standards are *Joseph Whitworth* and *Barclayana*, both superior varieties.

As comprising some of the most striking sorts which were flowering in the beds the following were noted as superior:—

*Mrs. R. Holford*, rich salmon; fine bold truss. Remarkably effective.

*Lady Claremont*, rosy scarlet; large and good.

*Charles Bagley*, crimson; very free and fine.

*Lady Armstrong*, rosy pink; splendid trusses. Very superior.

*Arthur Helps*, rich crimson edge, light centre; fine.

*Titian*, clear rosy scarlet. One of the best.

*Countess of Normanton*, soft lilac, richly spotted; a grand truss. Excellent.

*Princess Mary of Cambridge*, rosy purple and white; very attractive.

*Countess Granville*, purple edge, white centre; splendid truss. Very striking.

*Mrs. William Agnew*, warm rose and yellow; grand truss, and altogether superior.

*John Walter*, glowing crimson; fine pyramidal truss. Very effective.

*Frederick Waterer*, somewhat similar to the preceding. Very good.

*Kate Waterer*, rosy crimson, greenish yellow centre, superbly spotted. A splendid variety.

*Purpureum elegans*, rich deep purple. One of the best of its class.

*Madame Van der Weyer*, rose; fine truss.

*Lord Palmerston*, rose; very large truss. Early and effective.

*Sir J. Sebright*, red, bronze blotch; free and fine.

*Dhuleep Singh*, nearly black.

*Pictum*, or *Lowii*, white and yellow; very effective.

*Gloriosum*, soft lilac, fringed; bold truss. Excellent.

*Lord Eversley*, rich crimson; exceedingly fine.

*Notabile*, warm rose, dark spots; grand in truss and foliage.

*Charles Dickens*, crimson; very striking and effective.

*Mrs. Shuttleworth*, scarlet, light centre; a very fine variety.

*Mrs. Milner*, rich glowing crimson; dwarf and good.

*Mark Antony*, lilac, bronze eye; very effective.

*James Marshall Brooke*, crimson and bronze; very fine.

*James McIntosh*, rosy scarlet; a very superior variety.

*Kettledrum*, purplish crimson; rich and fine.

*The Queen*, white and greenish yellow; a queenly flower, pure and majestic.

*Stella*, rose, richly blotched; very fine.

*Raphael*, crimson; noble truss. Very brilliant.

*Alaric*, rich claret; very free and very fine.

*Mrs. John Clutton*, white and yellow; a superior and charming variety.

*Purity*, somewhat similar to the above; excellent.

*James Bateman*, crimson, white stamens; noble truss. Very handsome.

*Alexander Dancer*, rosy crimson; very beautiful.

*Mrs. T. Waine*, purplish rose; free and fine. One of the best.

*Madame Masson*, white and yellow; a charming variety.

*Album Triumphans*, somewhat like the preceding; very good.

*Cruentum*, rich lake; splendid.

*Standish's Perfection*, white and yellow; an excellent and telling variety.

The above are a few of the best varieties which were flowering in Mr. McIntosh's rich and extensive collection. They may be considered as possessing sterling merit, and worthy of being added to all collections not containing them. Rhododendrons are grown at Duneevan in great perfection. The soil is naturally light, and the subsoil is moist. Water is "laid on," and is given to the beds as they require it, and there is no spoiling of the plants by crowding. The grounds are in the most perfect order imaginable, not a blade of grass being out of place, or a daisy, stray leaf, or weed to be seen on lawn, border, or walks. It is indeed a model garden, owned by a liberal and appreciative possessor, and in the care of an industrious and able gardener, Mr. Taylor.

On the occasion of a former visit the extraordinary terms of confidence and friendship which existed between Mr. McIntosh and his feathered friends was noticed by the robin picking the crumbs from the mouth of its protector, following him about the lawn, ever on the watch for a kind word and a dainty morsel. The same good feeling continues to exist, and almost similarly familiar is a thrush, a bird usually so timid and mistrustful; but what may not be accomplished by kindness and perseverance?—J. W.

### THE COLOURING OF GRAPES.

From what I have both seen and read I fear that brown and red Grapes are unusually prevalent this season. It is not easy to account for this; in fact, in all cases it is impossible to do so, but I have a strong suspicion that much of the evil is due to insufficient support at a critical period. I suspect that many are afraid to water their Vine borders when the fruit is approaching ripeness. That, above all others, is the time when the Vines especially need support. For some time the sun has been very powerful and the air dry, transpiration from the foliage has been extreme and possibly excessive—that is, the fruit has been deprived of the support necessary to perfect it in obedience to the demands of a dry atmosphere and a disproportionate amount of water to meet those demands, and to provide a surplus as it were of nourishment for the full and due support of the Grapes.

It is sometimes, if not frequently, forgotten that the fruit of a Vine or any other tree is almost solely dependant on what may be termed a surplussage of support to perfect it. If the supply of nourishment is on a limited scale the fruit does not have priority, and have the "first cut" as it were, leaving the "crumbs" for the extension and general sustenance of the Vine; but first of all the structural wants of the Vine must be attended to, the demands of a dry atmosphere must be met, and evaporation and transpiration must and will go on, even if the fruit is deprived of necessary support. It may be urged that the primary object of a tree is to perfect its fruit, but that dictum can only be admitted by acceptance of the important point that the tree must be a perfect tree before it can produce perfect fruit.

In the matter of Vines when the Grapes are imperfect it is simply an expression of the imperfect state of the Vine producing them. The structural parts of the Vine—its construction and extension—have, with the extraordinary demand of a dry and highly heated atmosphere, required all the support that the roots could supply, leaving an insufficient surplussage for perfecting the fruit. That is the great and main cause of a deficiency of colour in Grapes. The deficiency may appear to be traceable to other causes, as the sudden and violent removal of foliage, checks arising from sudden variations of temperature, &c., but in reality the cause is the same—a deficiency of support at a critical period.

An uncoloured Grape is an imperfect Grape. It may be juicy, of full size, and even of good flavour, but it is still im-

perfect, lacking something that it ought to have had, accounting for its deficiency. The skin of an uncoloured Grape is defective, being deficient not only in colour but also in substance, and these deficiencies arise from the same cause—inadequate support. This is plainly shown in the case of over-cropped Vines. That is the greatest cause of the non-colouring of Grapes; yet some Vines, which are apparently not heavily cropped, do not produce perfectly coloured Grapes, but that in general means that the constitution of the Vines is weak, and though they are not apparently heavily cropped they are so in reality, and the Grapes do not receive the support which they need to carry them to perfection.

Very frequently Vines are deprived of much support by some mismanagement at the time of colouring. Common it is that as soon as the Grapes show colour to keep the air of the house as dry as possible. Not a plant must be watered in the house or a drop of water spilled on the paths, the border containing the roots receiving at the same time an extra supply of water. It is only Vines that are in full vigour and lightly cropped that can colour their Grapes under that practice. The drier the air of a house is kept the greater is the demand of the foliage for moisture from the roots. Transpiration is then increased to a considerable extent, and it is not until the foliage is satisfied and has exhausted itself in attempts to satisfy the thirsty air that material support can be afforded to impart substance and colour to the skin of the Grapes. Where a dry atmosphere is produced extra water must always be supplied to the roots of the Vines, to meet the necessarily greater demand for moisture which the foliage and the air require. But while the air of vineries is frequently kept dry during the colouring period it is not by any means the rule to give extra water to the roots, and consequently the fruit is deprived of support at the very time that extra support is needed, and imperfectly coloured fruit is the natural consequence.

It is not necessary or advisable to keep the atmosphere of a house perfectly dry at the time the Grapes are colouring; air cannot be admitted too freely, but the atmosphere should also be in a moderately moist state. If we look at Vines which are grown in the open air, we note that they generally colour in the most perfect manner under the heavy dews and frequently heavy rains of autumn. A thirsty atmosphere does not at that period exhaust the Vines, but they hold in store sufficient support to be appropriated by the fruit. The fruit also colours at that period even in dull weather, and when daylight is neither intense nor of long duration. This suggests that glaring light is not a requisite of black Grapes at the colouring period. Cultivators should therefore be cautious in removing laterals at that time, or more light may be admitted than is needed, and at the same time a check be given to the flow of sap.

At the colouring period above all others there must be no check by any cause. Instead of withholding support by producing a dry atmosphere, extra support should be given. Moisture in the atmosphere may be reduced when the Grapes commence colouring, but an additional supply must be given to the roots to meet the increased demands of the Vines, which must necessarily follow when the air is kept drier than it has been heretofore. It is an excellent plan as soon as colour is seen on the Grapes to give a soaking of tepid manure water to the borders. That is just the time when support is specially needed, not only because the crop just then exerts the greatest exhaustive strain on the Vines, but because a drier atmosphere is calling aloud and must have its share of moisture, which would otherwise be appropriated by the stems and fruit.

In colouring Grapes there are three points worthy of being kept in mind. There must be no checks by a sudden removal of laterals, a free circulation of air is essential, and an adequate supply of water (especially to the roots) is indispensable.—A NORTHERN GARDENER.

### GLORIOSA SUPERBA.

MANY years ago this plant was grown in a garden in which I was a very youthful helper, and I remember admiring its singular form and attractive markings. It was much valued as affording cut flowers, of which too many of them could never be produced. The plant was grown in a Pine pit, starting the roots in spring, and keeping the pot plunged in the tan of the pit. I left that place when still a youth, and for a quarter of a century never once saw a plant or flower of the *Gloriosa*. It was, however, firmly impressed on my mind, and I was delighted to recognise my old favourite

in a stand of flowers belonging to Mr. Cypher at the last Aquarium Show. There it was in all its quaintness, so singular and conspicuous as to arrest the attention of many visitors, not one in ten, even amongst the gardeners, knowing what it was. I was amused at overhearing some whispered discussions amongst groups of young men, some of whom considered it to be an Orchid, others deciding it to be a "Lily of some sort." It was, however, my long-lost flower the *Gloriosa superba*.

I am surprised that a flower so striking is not in more general cultivation, and I am sure it would be useful if any who happen to be familiar with its mode of culture and increase would communicate their experience. For myself I am not able to say more than that it is a distinct, singular, and beautiful flower, green at first, afterwards assuming yellow and brown tints. It is totally unlike any other flower that I am acquainted with, and I think must be worthy of extended culture. Can any of your readers throw any light on this remarkable plant and the best mode of growing and flowering it?—W. T. S., *Balham*.

### SIR JOSEPH PAXTON STRAWBERRY.

COMPLAINTS have arisen of this valuable Strawberry proving barren during the first season after planting. I have experienced the same result on more than one occasion, but have never failed being rewarded with splendid crops in succeeding years. I cannot conceive a greater mistake being made than destroying healthy plants of this Strawberry because they produce "nothing but leaves" the first season—that is, assuming that the runners are known to have been produced by fruitful parentage.

Sir J. Paxton is particularly prone to unfruitfulness when in a young state if growing in light soil. Plants growing robustly in soil of this nature should not be watered or manured, but the soil should be trodden very firmly round the roots. The plants must not be crowded by their own foliage, by runners, or by weeds. If the plants are too thick thin them out, removing if necessary every alternate row, so that light and air can have free access to the crowns. When this is done it is not necessary to cut off the foliage. Cutting off the foliage of plants growing closely together may induce fruitfulness, but the fruit will not be large; whereas by growing the plants thinly and allowing the foliage to remain will almost certainly result in superior fruit.

Sir Joseph Paxton is one of the most useful of Strawberries, producing heavy crops of handsomely shaped highly coloured fruit of good flavour, suitable alike for exhibition purposes and dessert; it is also good for preserving.

I have "assisted" at most of the principal horticultural exhibitions of this year, and I have observed that more than half of the prizes offered for Strawberries have been won with Sir Joseph Paxton. My advice to "J. T." and others similarly circumstanced is not to consider their plants as cumberers of the ground—not to dig about them and dung them, but to firm the soil in which they are growing, to keep them free from weeds or anything impeding the free action of sun and air to the crowns, to give the plants another year's trial and tell us of the results. As has been the case in my experience, the verdict will be, I think, that this is one of the most useful Strawberries in the garden.—AN EXHIBITOR.

### PROMOTING THE GROWTH OF EVERGREENS.

We have operated on twenty-seven sorts of Conifers, also Portugal Laurels, Evergreen Oak, Box, and Rhododendron, in all about sixty plants. The Conifers have been planted round the house for from fifteen to twenty-three years, and they average from 15 to 30 feet in height, but some of them are 40 feet high. We had observed that for the three or four years before the operation the trees had become stunted; and Mr. Thornton of the Heathside Nurseries gave it as his opinion that they were root-bound, and recommended the following treatment—viz., to take out the soil all round each tree for about 6 feet from the stem and fill-in with fresh soil. This was done to the depth of 18 inches by about 2 feet in width; the earth below the 18 inches having been broken up and left rough. The soil consisted of stiff loam to the depth of a foot and afterwards 3 feet of blue clay. About 8 inches of clay was removed, and the loam was mixed with sand and gravel. All large roots extending across the trench were left. The effects did not appear last summer—i.e., the summer

after the operation, but this year the growth has been extraordinary, especially in the Cedars, Wellingtonias, Deodars, &c. The Evergreen Oaks, which showed daylight through, are now dense with thick foliage—in fact the renovation is complete. Why would not this answer in every sort of stunted tree in orchards and elsewhere?—OBSERVER.

### STOCKS FOR ROSES.

HAPPENING to come in contact with a great grower of Roses—one of the working bees who has produced some of the finest blooms that have ever been exhibited, winning high honours for their owner—I asked his opinion as to the best stocks for Roses. This man told me willingly all he knew, concluding in his own plain vernacular in the following words—"I'll tell you what it is sir, there's a lot o' rot about Rose stocks."

He recounted that he had been growing prize Roses for many years, and assured me that if he had been limited to the use of one kind of stock—whether Manetti, hedgerow Briar, or seedling Briar—that he should not have gained half the prizes for his employer that he has done. He assured me as a large grower and regular exhibitor that in some seasons one stock is the best, and in other seasons another produces the best blooms, and that the only way to ensure the best Roses over the greatest length of time and in different years is to grow Roses on all sorts of stocks. By all sorts he means Manettis, hedgerow Briars, seedling Briars, and Briars from cuttings, having also some Roses on their own roots.

For garden decoration he considers Roses from cuttings highly suitable, but they give but a small proportion of exhibition blooms.

The seedling Briar he considers a good stock, but not better than cutting Briars, and invited me to see hundreds of plants growing side by side, some of the stocks having been raised from seed and some from cuttings, and of which it was not easy to say which were the best. He considers stocks from cuttings fully as good as stocks from seed, and in fact is inclined to give them the preference, but only on the ground, I think, that they are more quickly raised. His opinion is, that if people have a fancy to have stout plants on the seedling Briar they must be prepared to pay for their fancy on account of the time required to raise the stocks to a size ready for working.

Manettis he considers are not adapted for cold heavy soils; but for rather light soils, and where plenty of water can be given, or the ground can be heavily mulched with manure, no stocks can produce finer blooms. He has also a great respect for the old hedgerow Briar, provided the stocks are good and are planted in good time. Especially early in the season he states that he cuts more prize blooms from the Briar than from any other stocks, and that if he was ordered to cease growing the old Briars he should have to cease exhibiting, or at least would be absent from many shows at which he now stages first-class collections.

No one, he asserts, can win large prizes year by year who grows only one kind of stock. Such may during some seasons sweep the boards, but a blank is sure to come, simply because no one stock is the best stock for all seasons and under all circumstances. "If you want to win, sir," said my informant, "take my advice and grow on all the stocks, and the probability is that well-selected and well-managed Briars, much as has been said against them, will give you more first-class blooms than any other stocks;" concluding with the above remark, that there is "a lot o' rot about Rose stocks."

I was much impressed with the remarks of this experienced and actual worker amongst Roses, thinking they contained much truth, and I am inclined to think also that they are worthy of a place in the Journal.—M. D.

### PORTER'S EXCELSIOR POTATO.

OBSERVING that one of our leading firms have submitted tubers of this Potato in proof of its earliness, I may note that it is not only an early Potato, but is also of excellent quality. It is not, however, contemporary with our earliest sorts, but ripens about the same time as Myatt's Prolific, which may be called early for a round Potato. Excelsior is also fairly productive, and the quality is good. But it is as an exhibition Potato that this variety will be most esteemed, nearly every root, in proper soil, producing tubers of the correct size and remarkably handsome, equalling, if not surpassing, the best samples of Paterson's Victoria in October. For summer exhibitions of vegetables where round Potatoes are seldom attrac-

tively shown Porter's Excelsior will be found to carry considerable weight where a good dish of round or pebble-shaped Potatoes are required. In fact it is for purposes of exhibition that this Potato will be primarily cultivated, the quality of older varieties being not only equal to it for table purposes, but they can be more cheaply produced. Those requiring a handsome Potato should add Porter's Excelsior to their lists of sorts and so gratify their fancy; for there is now-a-days much enjoyment derived from growing Potatoes to "look at."—F. F.

### ASARUMS.

MANY moist places in our shady walks often present a naked and bare surface. These are the very places the Asarums should occupy. Some of them were introduced from other countries, as *Asarum canadensis*, which is said to have found its way to us from Canada so far back as 1713. They are thought by some to be more curious than pretty. Be that as it may, there is something both curious and pretty about them; their beautiful leathery Ivy-like foliage has an appearance different to all other plants, while their half-hidden curious flowers may easily be unnoticed by the casual observer. They are useful plants for the purpose named above and for damp rockeries, and being evergreen makes them more desirable still. From North America we have *A. arifolium* and *A. grandifolium*. From Virginia we have *A. virginica*. *Asarum europæum*, which our figure represents, we call our own, and it only requires to be seen in its native home to be admired. It is said to possess powerful medicinal properties, used in cases of sickness as an emetic.

The plants are easily cultivated, and when once established require to be left alone. Loam, peat, and leaf mould afford them a suitable medium to develop themselves in. I have not tried them, but I have an impression they would prove useful plants for edgings in damp shady places. They are increased by division almost at any time, but spring is the best time when growth has commenced. I have seen them quite at home in peat beds among other peat-loving plants in partial shade. If we had a variegated form of this plant I am inclined to think it would be an acquisition to our numerous hardy plants that are now taking the proper places from which they have so long been excluded.—N.

### ENDIVE.

ENDIVE is one of the most important of salad vegetables, and a supply of it is provided for use during the winter months in all well-managed gardens. It is a very old vegetable, supposed to be a native of China and Japan, and was introduced into Europe in the early part of the sixteenth cen-

tury. It is, however, so thoroughly established in this country as to be considered by many an indigenous plant. The Chicory, *Cichorium intybus*, is commonly known as the wild Endive, and undoubtedly is a wild plant in many parts of England; but this is a perennial plant, the common salad Endive, *Cichorium endivia*, being an annual.

There are two distinct varieties of Endive—the broad-leaved or Batavian, and the curled Endive, and of both these there are many sub-varieties. An excellent form of the broad-leaved is Fraser's or somebody's Round-leaved. This has very broad midribs, which when blanched are of ivory whiteness, and possess an agreeable nutty flavour. Endive is one of the most useful of winter salad vegetables, growing freely, being tolerably hardy, and blanching quickly. The green curled varieties are very attractive in appearance, and "set off"

to great advantage a basket of salads for exhibition purposes. Both kinds are highly worthy of culture, the curled varieties for appearance and also possessing good flavour, the broad-leaved for everyday usefulness and high edible quality.

For producing a full supply throughout the autumn and winter months, about three sowings made at intervals in July, or two sowings in July and one in August, are all that are really necessary. If ground is vacant it is an excellent plan to sow the seed very thinly in drills about 18 inches apart, thinning-out the plants immediately they are large enough to be handled. The plants also may be raised in beds and transplanted; but it is highly important that they are not grown thickly in the seed beds, as the plants are neither so stout nor so hardy as when grown thinly throughout their whole course. The latest July or early August sowing is generally the most useful, this crop re-

quiring protective care, and it will yield produce throughout the winter. At the approach of frost the plants may be transferred to spare frames or frost-proof sheds, and from thence, as required for use, into warm and darkened places as Mushroom houses, where blanching is perfectly effected. Before very severe weather many plants are blanched in the garden by covering them with pots, saucers, or tiles, the plants being covered when the foliage is quite dry. Blanching is also perfectly effected by completely burying the plants in dry soil. I have frequently buried them, roots uppermost, on the south side of rows of Celery, and have dug out most perfect Endive throughout the month of January. Some of the plants may decay entirely, but many will have their hearts preserved, the quality of which being very crisp and sweet. It is of the greatest importance that they are perfectly dry when buried, and also perfectly uninjured by frost, or decay of the plants will be certain.

Salads are so generally esteemed in winter as well as summer, that good breadths of Endive must not be neglected, therefore it is that I draw attention to this indispensable salad vege-

Fig. 5.—*Asarum europæum*.

table at the time when seed should be procured and sown.—  
R. FISHER'S PUPIL.

### WIMBLEDON HORTICULTURAL SHOW.

WIMBLEDON and the district round about with good gardeners—men who have taken active steps to advance the work in which they are engaged. Besides the gardeners there are many others—employers of gardeners, &c.—who are desirous of fostering a taste for horticultural pursuits, seeking to perfect the higher branches of the art and endeavouring to inculcate a love for the cultivation of flowers, fruit, and vegetables amongst amateurs and cottagers. To this end the “Royal Horticultural and Cottage Garden Society” was established—a Society having a long roll of influential patronage, a practical working committee, and active and efficient officers. Last year the Exhibition was a partial failure owing to extreme wet weather on the show days; this year witnessed the other extreme—a cloudless sky and tropical sun, preventing, it is to be feared, many visitors from attending the Exhibition, for cases of sunstroke occurring on the adjoining common where our volunteer army are encamped could not have otherwise than a deterring effect on the minds of several dwellers in the district, who thought it prudent to remain “in the cool.” Still the Exhibition was well patronised, and was spoken of by visitors as the best that has been held at Wimbledon.

The tents were pitched by permission of E. Halton, Esq., in the grounds of Lauriston House, the lawn, &c., being also kindly open to all visitors. Lauriston House is an old structure once occupied by Wilberforce the celebrated philanthropist, and the Scotch Fir is shown which he is reputed to have planted. The lawn contains many fine deciduous trees and Conifers, and the beds of Geraniums, &c., are extremely gay, the best we have this year seen, and the entire garden is evidently managed by an able and industrious man in Mr. Chandler.

In support of the Society special prizes were offered by Lady Peck; the Misses Reeves, Wothays; F. B. Thomas, Esq., East Hill House; R. F. Dunbar, Esq.; and Messrs. Dick Radclyffe and Co. In the cottagers' division several “specials” were also provided by ladies and gentlemen of the district. As contributing to the value and attractiveness of the Exhibition, choice and extensive groups of plants were arranged by Messrs. James Veitch & Sons, the Royal Exotic Nursery, Chelsea; Messrs. Jackson & Sons, Kingston-on-Thames; Messrs. Rolleston and Sons, Tooting; and Mr. Kinghorn, the Nurseries, East Sheen. Messrs. Dick Radclyffe & Co. also exhibited attractive cases of Ferns, &c. In the several classes there was good competition. Mr. Lyne, gardener to A. Schlusser, Esq., Belvidere, Wimbledon; Mr. Jordan, gardener to J. Boustead, Esq., Cannizzero House; Mr. Bentley, gardener to Sir T. Gabriel, Bart., Edgecumbe Hall; Mr. Smith, gardener to G. C. Joad, Esq., Oakfield; Mr. Roser, gardener to T. Shaw, Esq., Inner Park Road; Mr. Stratton, gardener to Miss Forbes, &c., were amongst the principal exhibitors. The cottagers' classes were admirably filled, and the numerous dishes of fruit and vegetables, also of cut flowers, window plants, and boxes were in the highest degree creditable to the exhibitors, and encouraging to the promoters of the Exhibition.

We cannot do more than note the general character of the display, enumerating a few of the prominent exhibits. The principal centre of attraction was the marquee in which the large plants were arranged. At one end was the collection of Messrs. Veitch, including Roses in pots, also boxes of cut blooms; and at the other the excellent group of Messrs. Jackson and Sons. The most striking plants on the central stage were the Caladiums from Mr. Jordan. These were truly magnificent plants, and which would show to advantage at the best metropolitan exhibitions; indeed, it is a question if plants equal to them have been exhibited in London. They vary from 4 to 6 feet in diameter, every leaf being in perfect health and colour, and skilfully tied, the plants being firm and symmetrical, yet not severely formal. The sorts are Meyerbeer; Excellent, an improvement on Chantini; Belleyme, Prince Albert Edward, Triomphe de l'Exposition, brighter than Bicolor splendens; and Duc Adolphe de Nassau. An idea of the vigour of these plants may be imagined when we state that the corms exceed a foot in diameter. The plants are in 12-inch pots, which are, however, partly hidden by the exuberant foliage. Mr. Stratton, Mr. Cole, Mr. Law, and Mr. Lyne also exhibited well-grown and highly-coloured plants. Such plants as Mr. Jordan's are worth more reward than the mere 15s. prize, and the Judges should have recorded them some special token of recognition.

Next in point of attraction were the Zonal Pelargoniums from Mr. Roser and Mr. Lyne. Mr. Roser's plants in 6-inch pots were admirable examples of culture, the foliage and trusses being alike in great vigour and perfection. Corsair and Richard Dean were especially brilliant amongst the scarlets, and Dr. Tate and Mrs. Turner were the best of the pink varieties. The same exhibitors and Mr. Law staged capital plants in 8-inch pots, also good collections of double varieties. Ferns were well

exhibited by Mr. Jordan, Mr. Bentley, Mr. Chapman, gardener to P. Maccabe, Esq.; and Mr. Turner, gardener to W. T. Pritchard, Esq. Mr. Jordan had a splendid plant of *Adiantum concinnum latum*, good *Gymnogrammas*, a *Neottopteris*, and a fine *Davallia Mooreana*. Fuchsias were numerous, and were characterised by size rather than quality; still many good plants were staged by Mr. Stratton, Mr. Lyne, and Mr. Law. Gloxinias were very good from Mr. Lyne and Mr. Curtis, gardener to J. Barlow, Esq. Achimenes were also very fine from Mr. Jordan, and good from Mr. Lyne and Mr. Turner. The best stove and greenhouse plants came from Mr. Jordan, Mr. Moorman, gardener to the Misses Christy, and Mr. Bentley; Mr. Chapman, Mr. Law, and Mr. Jordan also exhibiting well in the miscellaneous collections, *Begonia Vesuvius* from the last-named cultivator being extremely effective. For the best specimen flowering plant Mr. Jordan had the place of honour with a good *Clerodendron Balfourii*, Mr. Smith occupying the same position with a capital example of *Rhaphis flabelliformis* in the class for specimen foliage plants. Very good *Lycopodiums* came from Mr. Turner, Mr. Bentley, and Mr. Cooling.

Table plants were admirably exhibited. For twelve plants in pairs Mr. Jordan was placed first, Mr. Lyne second, and Mr. Bentley third. For six plants the prizes went respectively to Mr. Smith, Mr. Law, and Mr. Moorman. The *Crotons* and *Dracenas* were in admirable health and colour. These collections were highly creditable to the cultivators, most of the plants being superior, but a few—just a few—would have been as well left at home.

A class was provided for eighteen plants in 8-inch pots, which brought out six competitors, the collections wholly occupying a small tent. Mr. Smith was well placed first with plants of high quality and tastefully arranged. This group included a capital *Aralia Veitchii*, *Cocos Weddelliana*, a very good *Paullinia thalictrifolia*, *Crotons*, *Dracenas*, a *Saccolabium*, *Anthurium*, and *Cypripedium*. Mr. Lyne was a good second with larger plants, and Mr. Bentley third. Classes of this character are steps in the right direction, as opening a way for exhibitors who have neither large plants nor large houses, but who have nevertheless worthy specimens of culture which they can arrange with taste. It becomes a question whether it is not preferable to apportion a convenient amount of space and allow each exhibitor to occupy it with any number of plants he likes, awarding the prizes to the most healthy—not necessarily the largest—plants, and their most tasteful disposition. Such a plan would bring out fresh ideas in grouping and be attractive and instructive, and would open a way also for securing the largest number of competitors. According to the ordinary framing of schedules many gardeners are debarred from showing because they have not the stipulated number of plants of a uniform size, but they could occupy 30, 40, or 50 square feet of space in a creditable and attractive manner. Some of the groups at Wimbledon were not well arranged, and “education” in the artistic grouping of plants is generally needed. Semicircular groups of plants along both sides of a tent, as was the case at Richmond, have a beautiful effect, and the idea is worthy of being carried out more generally at local shows.

Roses were not extensively exhibited. For twenty-four blooms Mr. Moorman, Mr. Fanning, Roehampton, and Rev. J. M. Brackenbury, Wimbledon, were placed in the order named for good collections; and for twelve blooms Mr. Scott, Pelham Road, staged a collection of high quality. Bouquets were good, also “button-holes,” especially from Mrs. Lyne, Miss Oliver, and Mrs. Jordan. A Rosebud, white Jasmine, Stephanotis, and Maidenhair Fern were the prevailing associations.

Stands of cut flowers were very attractive, especially one composed of “annuals” from Mrs. Jordan; but *Ageratums* are not annuals, and Mrs. Jordan was lucky in not having been disqualified. There were dozens of “soup plates” arranged with flowers and fruit which were very attractive; but for Lady Peck's prizes for cut flowers of hardy perennials the exhibits were poor, and very few of the flowers were named.

Fruit was limited in quantity and not superior in quality. There was one miserable Pine, most of the “Black” Hamburg Grapes were brown, and the white Grapes were unripe. The prizes were rightly awarded to the smallest bunches as being fairly well finished. For black Grapes Mr. Tucker, gardener to Mrs. Jones, Mr. Lee, gardener to G. Turner, Esq., Oaklands, and Mr. Bentley were successful; and for white Grapes Mr. Barker, gardener to J. Murray, Esq., was first with Frontignans, Mr. Lee being second with Muscats, and Mr. Ansell third with Foster's White Seedling. For Melons Rev. J. M. Brackenbury was first with Golden Perfection. Strawberries, Currants, Gooseberries, &c., were of fairly good quality.

Vegetables were freely exhibited, but as a rule they were too large, and deficient in quality and high finish. For a collection Mr. Lyne, Mr. Jordan, and Rev. J. M. Brackenbury were placed as named. Cucumbers were too old and large, and the prize was given to the largest and oldest. The best brace for table quality came from Mr. Ansell, and were not noticed. The cottagers exhibited largely, and worthily won the several prizes.

The Exhibition was a successful one, and Mr. Appleby, the Secretary, superintended with his known courtesy and activity, and was well supported by several members of the Committee. Major-General Poulton ably presided at the luncheon on the first day of the Show. He is an active patron of the Society, and by his and other influential aid it can hardly fail to prosper. The Exhibition closed on the 13th inst.

## ROYAL HORTICULTURAL SOCIETY.

JULY 19TH AND 20TH.

THE Exhibition which is now being held at South Kensington, and which closes this (Thursday) evening, is the last of the metropolitan summer exhibitions. The schedule was a remarkably modest one, including but nine classes for plants, four for Carnations and Picotees, and fourteen for Roses. Even so far as regards the latter flower there was no pretence of making a "great Rose Show," prizes only being offered for twenty-four, twelve, and sixes; a wise decision on two grounds—the lateness of the season, and the great opportunities that have been provided (and responded to) in other places during the legitimate Rose season. But as supplementary to this limited provision of classes there was valuable subjunctive aid afforded by the competition for the important special prizes which were offered by the Pelargonium Society, by Messrs. Veitch & Sons for fruit, and by Messrs. Carter & Co., Sutton & Sons, Hurst & Sons, and Mr. Monro for vegetables. The Pelargonium Society offered upwards of £60 for competition in twelve classes, Messrs. Veitch and Sons upwards of £100 in eight classes, and the vegetable prizes were extremely liberal. Besides these additions to the Society's prizes the valuable volunteer collections of plants from the leading nurserymen were arranged in the large marquee with the same effect which these plants always produce, and which contribute so powerfully to the success and attractiveness of an exhibition. Thus is the position of this old Society recognised in being rallied round and supported as the accepted head and centre of the horticultural craft in Britain. Let us now look at the results of these combined efforts. In the aggregate the Show must be described as one of the best which have been arranged in London for a very long time. The fruit for Messrs. Veitch's prizes make a noble display, occupying about 100 feet-length of table, and the vegetables are extensively exhibited; the Peas are in wonderful excellence, and other vegetables are highly superior—thanks to the enterprise of the firms named and skilful cultivation.

Extensive and attractive miscellaneous groups of plants are arranged in the large tent, and the boxes of cut Roses arranged in front of them, and especially the cut blooms of Carnations and Picotees, produce an excellent effect. Mr. Turner, Slough, set up groups of specimen Ivies extremely ornamental, and Palms. These are fringed with table plants and Roses—a most extensive and admirable group. Messrs. Veitch & Sons occupy the centre of the tent effectively as they always do, the plants being composed of Palms, Yuccas, Liliiums, *Nepenthes*, &c., fringed with Orchids, Gloxinias, and Ferns. Messrs. Jackson & Sons, Kingston, and Mr. B. S. Williams, Holloway, arranged capital collections of stove and greenhouse plants, the *Heaths*, *Allamandas*, *Statice*, *Orchids*, &c., being highly ornamental. Mr. Wills arranged a highly attractive collection, consisting of very tall green *Dracenas*, Palms, and Tree Ferns, the base being covered with *Lycopodium*, in which Roses, Water Lilies, &c., are artistically disposed. He also exhibits golden *Caladiums* and other new and choice plants. Messrs. Osborn & Sons, Fulham, sent a group composed of fine-foliaged plants in which a splendid specimen of *Davallia Mooreana* is conspicuous. Mr. Wimsett, Ashburnham Park Nursery, arranged a similar group; and Messrs. Lane and Son specimen Ivies. Messrs. Rollisson & Sons sent a very ornamental collection of plants. Mr. Aldous, South Kensington, arranged a collection in which *Hydrangeas* and *Kalosanthes* are very effective. Mr. Laing staged Palms, &c., with handsome Bicolor *Pelargoniums*; and Messrs. E. G. Henderson and Sons exhibit new double and other *Pelargoniums*. Messrs. J. & C. Lee, Hammersmith, arranged a large and ornamental collection of fine-foliaged plants and Liliiums; and Mr. Burley, Brentwood, large Palms, *Phormiums*, &c.

Messrs. Veitch & Sons sent a most noteworthy collection of Figs and Peaches in pots, the trees being remarkably clean and healthy, and heavily laden with fruit. Fruit trees also come from the Society's garden.

Glancing briefly at the classes we note that for six *Fuchsias* (amateurs) Mr. Weston, gardener to D. Martineau, Esq., Clapham Park, is first with healthy and not too formal pyramids 4 to 5 feet in height; Mr. Lambert, gardener to H. W. Segelcke, Esq., Dulwich, being second. For twenty-four *Fuchsias* in not less than twelve kinds, in pots not exceeding 8 inches in diameter, Mr. Lambert is first for well-flowered plants, Mr. Weston having the second place. Mr. Pestridge exhibits in the nurserymen's class. The trade growers, however, seldom devote their space to specimen *Fuchsias*.

For twelve Liliiums in pots, in not fewer than four kinds (open), Mr. Turner, Slough, has the first prize with *L. auratum*, *L. lancifolium roseum*, *L. Fortunei*, *L. Humboldtii*, and *L. eximium*. *L. auratum virginalis* in this collection is very chaste and effective. For a collection of twenty-four varieties of succulent plants suitable for bedding purposes in pans 12 inches in diameter Mr. Dean, Ealing, is the only exhibitor, and is awarded the first prize.

[Considering the recent tropical weather there is an admirable display of Roses. The prizes will be found in the advertised list of awards, and the collections will be noticed next week.]

**CARNATIONS AND PICOTEES.**—Of these "D. Deal," remarks that it was pleasant to see the goodly number of exhibits in this class, but at the same time it was small in comparison to what the merits of the flowers, their extreme beauty and fragrance, deserved. It was in a great measure owing to the exertions of Mr. E. S. Dodwell that this result was gained, and that the pleasure of meeting such northern growers as Messrs. F. D. Horner, Rudd, Bowers, Simonite, and Lord was given to those interested in them in the south, and it was pleasant to have an opportunity of exchanging ideas on a subject on which we all loved to talk. In the open class two excellent stands, coming close to one another, were exhibited by Mr. Charles Turner and Mr. Douglas, the prizes going in the order named. Mr. Turner's flowers were *Flora's Garland*, *r.f.*, an old variety rarely ever seen; *Mrs. Holland*, *r.f.*; *James Taylor*, very beautiful; *Guardaman*, rather crowded; *Florence Nightingale*, *Lord Raneliffe*, *Lord Clifton*, *Mars*, *Ajax*, and *Clipper*. Mr. Douglas had Mr. Hextall, *Earl of Wilton*, *Isaac Wilkinson*, very good; *Rose of Stapleford*, fine; *Sportsman*, *Lord Raneliffe*, *Earl of Stamford*, *Rifleman*, *James Merryweather*, *Dreadnought*, *Superb*, and *Lord Lewisham*.

In the open class for Picotees the same results took place. Mr. Turner's flowers were *Rival Purple*, splashy; *Miss Foord*, *Miss Wood*, *Princess of Wales*, *r.f.*, good; *Mrs. Allcroft*, *r.f.*, good; *Cyathia*, rough; *Mrs. Niven*, good; *Mrs. Sumners*, *r.f.*; *Mr. Gibbons*, white, rather flushed; *Ethel*, very lovely, *r.f.*; and *Miss Small*. Mr. Douglas had *Mrs. Fordham*, too full and confused; *Norfolk Beauty*, good; *Mrs. Keynes*, *J. B. Bryant*, *ex. ex.*; *Juliana*, *Mrs. Allcroft*, *Ethel*, *Picco*, *Ganymede*, and *Princess of Wales*. The third prize went to Mr. Birch.

In the amateurs' class Mr. Dodwell was first in Carnations and also in Picotees, Mr. Douglas being second in both cases. Mr. Dodwell's Carnations were *John Keet*, *Squire Meynell*, *Sir J. Paxton*, *Mrs. Dodwell*, *Falconbridge*, *James Merryweather*, *Admiral Curzon*, *E. S. Dodwell*, *John Bailly*, *Lord Raglan*, *Premier*, and *Eccentric Jack*. His Picotees were *Princess of Wales*, *Miss Lee*, *Rev. F. D. Horner*, *Juliana*, *Mary*, *Mrs. Simmons*, *Edith Dombain*, *J. B. Bryant*, *John Smith*, *Alice*, *Minnie*, and *Alliance*. Mr. Douglas's flowers were Mr. Hextall, *Isaac Wilkinson*, *Lord Raneliffe*, *Rose of Stapleford*, *Rifleman*, *Earl of Stamford*, *James Merryweather*, *Mr. Cooper*, *True Briton*, *Annihilator*, *Marshal Ney*, and *Lord Lewisham*; while in Picotees he had *Mrs. Fordham*, *J. B. Bryant*, *Mrs. Keynes*, *Mary*, *Princess of Wales*, *Mrs. Hornby*, *Picco*, *Mrs. Allcroft*, *Admiral*, *Obadiah*, and *Norfolk Beauty*.

The fact that this has to be sent to press in about an hour after the prizes are awarded must make it a mere barren record of names, and one only has to express regret that so little is done for this very beautiful class of plants.

**PELARGONIUM SHOW.**—The plants are grouped in the large marquee. Many of them had received injury in transit, and the show cannot be described as either extensive or successful. The most varied and extensive collection of plants came from the Society's garden at Chiswick. The Judges withheld several prizes—a discretion wisely exercised, for many of the collections are anything but meritorious.

For twelve plants ("Florists' class"), in pots not exceeding 8 inches in diameter, prizes of £8 and £5 were offered. Mr. Catlin, gardener to Mrs. Lermite, Finchley, is placed first for healthy semi-globular plants about 2 feet in diameter, the trusses being numerous and fine. For four plants in 6-inch pots remarkable for finely-formed flowers irrespective of colour, Mr. Catlin has again the first place with *Heather Bell*, *Amazon*, *Lesbia*, and *Solon*, all raised by Dr. Denny; Mr. Evans, nurseryman, Penge, being second with *Rienzi* (Dr. Denny), *President Thiers*, *Mons. Lesseps* (Lemoine), and *Ace* (F. & A. Smith).

For twelve plants ("decorative class") in 8-inch pots the prizes were £8 and £5. Mr. Catlin is placed first for plants about 2 feet in diameter, healthy, and with numerous and fine trusses. A second prize was not given. Mr. Brise, Finchley, having the third place for rather starved specimens; Mr. Evans being placed fourth.

For thirty plants in 6-inch pots ("irrespective of class") the prizes were £6, £4, and £2. Mr. Catlin has the first place for healthy plants with fine trusses, but the plants were drawn, rendering free staking necessary.

For six double-flowering varieties in 6-inch pots, Mr. Evans, Penge, is awarded the second prize, and Mr. Catlin third, for plants of no particular merit.

For one hybrid Pelargonium of distinct and ornamental character, a "hybrid" Cape Pelargonium, *Pixie*, is exhibited by Mr. Pearson, Chilwell, a very attractive plant having no appearance of a hybrid; neither is *Happy Thought* exhibited by Mr. Evans, a hybrid, and the prizes were withheld. The other exhibits in these classes do not call for notice, and we do not hesitate to say that the Pelargoniums as a whole were not worthy of the prizes which were offered for them.

**MESSESS. VEITCH'S PRIZES.**—In the class for a collection of fruit in ten distinct dishes, first honours are awarded to Mr. Coleman, gardener to Earl Somers, Eastnor Castle, who exhibits Black Hamburg Grapes of the true Eastnor type, very fine but not perfectly ripe Muscats, a splendid Golden Gem Melon, and equally superior Bellegarde Peaches, Black Eagle Cherries, Frogmore Late Pine Strawberries, Governor Wood Cherries, Nectarines, Figs, and a Pine Apple—an admirable collection and deserving of its place. Mr. Sage, gardener to Earl Brownlow, is placed second with a fine collection, noticeable for a well ripened cluster of the Banana, *Musa Cavendishii*, highly superior Figs, and McLaughlin's Plums, good Grapes, Cherries, Peaches, Nectarines, and Strawberries. Mr. Tillyard, gardener to the Countess of Yarborough, Brocklesby Park, Brigg, is placed third; the *Grosse Mignonne* Peaches being very fine, and the rest good, but the Grapes not fully ripe.

In the next class for six dishes Mr. Bannerman, gardener to Lord Bagot, Blithfield, Rugeley, is placed first for a splendid dish of Black Hamburg and Muscat Grapes, Trentham Hybrid Melon, a Smooth Cayenne Pine, Royal George Peaches, and Elruge Nectarines. Mr. Cox, gardener to Earl Beauchamp, being second with a Prickly Cayenne Pine, a capital Golden Gem Melon, Royal George Peaches, Elruge Nectarines, very good Muscats, and fair Black Hamburg Grapes. The third prize is awarded to Mr. Wallis, gardener to E. M. Mundy, Esq., Shipley Hall, Derby, for very similar and very good dishes; an extra prize being awarded to Mr. Rutland, gardener to the Duke of Richmond, Goodwood. In this collection are very large but not highly finished Grapes. Five others competed.

For three bunches of Muscat of Alexandria Grapes the first prize is worthily awarded to Mr. Bannerman for splendid bunches, well filled and highly finished; Mr. Woodbridge, gardener to the Duke of Northumberland, being second also for capital fruit; Mr. Wallis being third for bunches and berries perhaps still better, but not quite so ripe as the *Syon House* Grapes. There are eleven competitors. In the class for three bunches of Black Hamburgs thirteen compete, the bunches being generally large, but many berries are deficient in colour. The first prize is awarded to Mr. Loudon, gardener to T. Barnes, Esq., The Quinta, Salop, for very large, well shouldered, and symmetrical bunches; the berries being not proportionately large, but well coloured. The weight of the bunches averages about 3 lbs. each. Mr. Somers is placed second for good bunches of remarkably fine berries; the third prize going to Mr. T. Coomber, gardener to J. A. Rolls, Esq., Hendre Park, Monmouth, for exceedingly clean fruit but small. In the class for three bunches of any kind except Muscat of Alexandria and Black Hamburg Mr. Bagot is first for remarkably compact and well-finished bunches of Black Alicante, Mr. Loudon being second with two bunches of Golden Champion, well filled but the berries somewhat irregular, and one Madresfield Court better than either, still not perfectly coloured, yet they beat three fine bunches of the Duke of Buccleuch near them from Mr. Wildsmith, but not ripe; the third prize going to Mr. Sage for large bunches of Buckland Sweetwater.

Full bunches and fine berries of the Duke of Buccleuch are exhibited in the miscellaneous class by Messrs. Lane & Son, Great Berkhamstead, but they are not quite ripe. As exhibited this is certainly a very promising Grape. A collection of fruit from Mr. Jones, Frogmore, contains two Cayenne Pines, weighing 18 lbs. 14 ozs.; Goliath and Victoria Plums, very fine; Buckingham Mignonne Peaches, a Royal Ascot Melon, Cherries, and poor Apricots. This collection is not in competition. Messrs. Lane & Sons exhibit Vines in pots carrying heavy crops of fruit.

A fine collection of Pines is exhibited, over forty in number. The first prize is taken by Mr. G. Wyness, gardener to G. Keith, Esq., Usan House, Montrose, N.B., with three splendid fruit of Ripley Queen; second Mr. W. Chamberlain, gardener to H. Thompson, Esq., Bushey, Herts, for three fruit of Queens; third Mr. G. Tillyard, for the same variety. Latterly Pines have not been well exhibited, but the collection here staged contains many excellent fruit.

For six Peaches of one kind the first prize is taken by Mr. G. Fennell, gardener to E. Cazalet, Esq., Fairlawn Park, Tonbridge, for fine well-coloured fruit of Noblesse; second Mr. J. Hill, gardener, The Poles, Ware, Herts, for Barrington, which is well coloured; third Mr. W. Coleman, gardener to Earl Somers, Eastnor Castle, for well-coloured fruit of Bellegarde. An extra prize is awarded to Mr. Tillyard, gardener to the Countess of Yarborough, Brocklesby Park, Lincolnshire, for fine specimens of *Grosse Mignonne*. Sixteen dishes are put

up. Among Nectarines there are some dishes of fine and highly-coloured fruit shown. The first prize going to Mr. A. Jamieson, gardener to the Earl of Crawford, Haigh Hall, Wigan, for Elruge; second to Mr. Edmonds, gardener to the Duke of St. Albans, Bestwood Lodge, Nottingham, for the same variety; third Mr. J. Hill, for Murrey Nectarine. The Peaches and Nectarines are remarkably well exhibited.

**VEGETABLES.**—These are numerous and excellent—by far the finest show that has been seen this year, occupying a length of table of 200 feet.

**MESSESS. CARTER & CO.'S PRIZES.**—For the best twelve dishes of vegetables, comprising Onions, Carrots, Turnips, Tomatoes, Cauliflowers, Celery, Commander-in-Chief Peas, Pedigree Windsor Beans, Dwarf Kidney Beans, and Porter's Excelsior Potatoes, sixteen collections are staged. The first prize of £10 10s. goes to Mr. G. T. Miles, gardener to Lord Carington, Wycombe Abbey; second to Mr. W. G. Pragnell, gardener to W. G. Digby, Esq., Sherborne Castle, Dorset; third to Mr. V. Arker, Cheltenham; fourth to Mr. Cross, gardener to J. Hough, Esq., Sidmouth, Devon; fifth to Mr. J. Bain, The Gardens, Downton Hall, Ludlow. For the best brace of Cucumbers Mr. J. Lockie, gardener to Lord Fitzgerald, Oakley Court, Windsor, won with Lockie's Masterpiece; Mr. R. Philips, being second with Tender and True; third going to Mr. Neighbour, gardener to G. Wythes, Esq., Bickley Court, Kent. Seventeen brace being exhibited. Melons: the best brace is contributed by Mr. T. Coomber, gardener to J. A. Rolls, Esq., Hendre Park, Monmouth, with Bloxholm Hall and Read's Scarlet-flesh; second Mr. J. Neighbour, with Bloxholm Hall and Hero of Bath; third Mr. O. Goldsmith, gardener to Sir W. Farquhar, Bart.

**MESSESS. SUTTON AND SONS' PRIZES.**—For six dishes of Peas, the first prize, a silver medal and £2, is won by Mr. R. Gilbert, gardener to the Marquis of Exeter, Burghley, with fine examples of Duke of Edinburgh, Duchess of Edinburgh, Commander-in-Chief, G. F. Wilson, Dr. McLean, and Laxton's Marvel. Mr. W. G. Pragnell, Sherborne Castle, being second with good dishes of Standard, Duchess of Edinburgh, &c. There are eight collections. For a collection of vegetables, twelve distinct kinds, the first prize, a gold medal and £5, is awarded to Mr. W. G. Pragnell, gardener to D. W. Digby, Esq., who has capital dishes of Early Nantes Carrot, Giant White Tripoli Onion, Sandringham White Celery, Porter's Excelsior Potatoes, Canadian Wonder Beans, Giant Emerald Marrow Pea, Tender and True Cucumber, &c. Mr. R. Gilbert, gardener to the Marquis of Exeter, is second, winning the silver medal; and Mr. W. Cox, gardener to Earl Beauchamp, Madresfield Court, securing the bronze medal, both contributing fine collections. There are twelve exhibitors. For a collection of Cucumbers and Melons the gold medal and £3 are awarded to Mr. W. Cox for Hero of Bath, Prince's Favourite, and Golden Gem Melons; Madresfield Prolific, and Duke of Connaught Cucumbers. Mr. W. G. Pragnell being second, having the silver medal, and Mr. R. Gilbert third with excellent examples. There are five competitors.

**MESSESS. HURST & SONS' PRIZES.**—For six dishes of Mr. Laxton's Peas the first prize of £4 is won by Mr. G. T. Miles, gardener to Lord Carington, Wycombe Abbey, who exhibits dishes of The Shah, Standard, Superlative, Laxton's No. 1, Fillsbasket, and Supplanter. The remaining prizes are taken by Mr. R. Gilbert and Mr. T. Bailey, The Gardens, Shardeloes, Amersham, in the order named. There are eleven exhibitors.

The prizes offered by Mr. Munro for Duke of Edinburgh Cucumber are awarded to Mr. R. Phillip, gardener to Capt. Jackson, The Deodars, Gravesend; second prize going to Mr. E. Bennett, Barnet; third to Mr. Cross, gardener to J. Hough, Esq., Peak House, Sidmouth. Eleven exhibitors.

**MESSESS. JAMES CARTER & CO.** exhibit seventy varieties of Peas which had been grown at their trial grounds, and also ripe seed of each variety, and a wonderful collection of Giant White Tripoli Onions, the bulbs averaging 20 inches in circumference, and with the size fine quality. Mr. Ormsen exhibits his celebrated upright tubular boiler, and Messrs. Dick Radclyffe & Co. attractive cases of plants. The Exhibition is highly worthy of inspection.

**FRUIT COMMITTEE.**—Henry Webb, Esq., in the chair. Mr. Brown, gardener to Hon. Mrs. Bathurst, Hyams, sent a dish of well-grown *Physalis edulis*, or Cape Gooseberry, to which a letter of thanks was awarded. A fine dish of *Beurré d'Amanlis* Pear was sent by J. S. Virtue, Esq., of Oatlands Park, grown by Mr. Cornhill, gardener, to which a cultural commendation was awarded. The same gentleman also exhibited a dish of Apples under the name of Gooseberry Pippin, but which proved to be the Winter Greening. Mr. J. Cox of Redleaf Gardens sent a dish of Redleaf Russet but the fruit was not fresh. A seedling Melon was received from Mr. Sinclair, Easthampstead Park, Wokingham. It is of large size, oval, and with a pale red flesh, but the flavour was inferior. The Rev. A. D. Stackpoole, Court, Chelmsford, sent an Apple of medium size, deep yellow, and with a tinge of red on one side. It was referred to the Director

to report upon at the next meeting. Mr. Wildsmith, gardener to Viscount Eversley, Heckfield, sent a seedling Melon called Heckfield Hybrid, which was unripe, and the Committee could not decide upon its merits. Mr. Cox, gardener to Lord Beauchamp, Madresfield Court, sent a seedling Melon called Hardy Prolific, scarlet flesh, which was not of good flavour.

Messrs. Lane & Son of Berkhamstead sent a dish of Ferdinand de Lesseps Grape of excellent flavour, but not quite ripe. A letter of thanks was awarded. Mr. R. Gilbert of Burghley Gardens sent a bunch of Abercainey Seedling Grape. Its bunch is like that of a small Black Hamburg, and the berries are small, black, and oval; the flavour is sweet and vinous, but it is so small the Committee did not consider it an improvement on others already in cultivation. The Hon. and Rev. J. T. Boscawen sent a dish of Dr. Hogg Grape, the flavour of which was delicious. A letter of thanks was awarded to Mr. Boscawen. Mr. D. Mills, Turnham Green, sent branches of Red Currants. Mr. R. Gilbert sent a dish of very fine Tomatoes called Jackson's, said to have been selected from Hathaway's. A cultural commendation was awarded.

**FLORAL COMMITTEE.**—W. B. Kellock, Esq., in the chair. A first-class certificate was awarded to T. Laxton, Esq., Stamford, for Rose Mrs. Laxton, a variety in the way of Marie Baumann but more cupped. A second-class certificate was given to Mr. Perkins, Leamington, for a Picotee, a self, full, and of a buff or straw colour, fairly smooth and full.

Messrs. Veitch & Sons received a first-class certificate for Utricularia Endressii, and also for Begonia Viscountess Doneraile, a variety with fine flowers of a rich crimson-scarlet colour. A vote of thanks for a finely bloomed plant of Vanda Lowii was given to H. G. Elliott, Esq., The Crescent, Downs Park Road, Clapton. A first-class certificate was given to J. H. Hawley, Esq., Ranelagh Gardens, Leamington, for Pelargonium Leamington Lassie, a bright pink semi-double flower of vigorous habit and large truss.

A most distinct and handsome Fern—a gold-spangled Gymnogramma—was exhibited by Mr. W. Brown, gardener to Mrs. Alston, Elmdon Hall, near Birmingham, for which he received a first-class certificate. A vote of thanks was given to G. F. Wilson, Esq., for cut blooms of various Lilies, including *L. californicum*, *L. longiflorum*, *L. eximium*, the Martagon Lily, &c. Mr. Charles Noble exhibited *Thujopsis borealis aurea*, a very distinct variety, with the habit vigorous, and if the constitution should prove hardy it will be an acquisition. Messrs. Sanders and Co., seed-growers, showed a dwarf white Candytuft, which though good was not considered sufficiently distinct to receive an award.

Dr. Denny of Stoke Newington exhibited two baskets of Pelargoniums—viz., Heather Bell and Globosa major. Mrs. Edward Fox, 44, Market Street, Brighton, exhibited some very natural-looking specimens of Roses modelled in wax, and which were highly commended. They were admirably executed.

### NOTES AND GLEANINGS.

WE omitted to notice that Messrs. Bell & Son of Norwich exhibited recently a stand of their new seedling hybrid Bourbon Rose CATHERINE BELL, and their seedling Tea Rose MRS. OPIE.

— THE seventh annual Exhibition of WINDOW PLANTS grown within the City was held on the 13th inst. in the gardens, Finsbury Circus. The Duchess of Teck, who was announced to distribute the prizes, arrived early in the afternoon. A splendid bouquet was presented to the Duchess by Miss Davies. The Duke of Teck, replying to some observations of the Lord Mayor, observed that the difficulties of cultivation were great, particularly in a place where bricks and stone had almost banished every vestige of vegetation. Here it was that the influence of flowers was most felt. They all knew their tendency to brighten the home and cheer the sick. The Royal Horticultural Society's silver medal was awarded to a youth named Jarvis for the best plant.

— AT the meeting of the HORTICULTURAL CLUB held on Wednesday last the following new members were admitted: Messrs. Charles W. Morriss, King's Lynn; Thomas Hanbury, Ashburton House, Croydon; Palazzo Orenzo, Mentone; Henry Ormson, King's Road, Chelsea; David Syme, Edinburgh, N.B.; Joseph Broome, Didsbury, Manchester; and David Allister, Mark Lane.

— PERSONS with horticultural tastes who visit the public gardens and grounds at Washington do not see all in that line worth their attention at the capital. Mr. Saul's nurseries and greenhouses on the Seventh Street road, just beyond the city borders, well deserve notice; and though, as a commercial place, it does not show specimens such as are found in the

Experimental and Botanic Gardens, its great collection of almost every class of plants is very interesting. Against the walls of his office and packing-house—brick and roughcast—have been trained a number of VARIETIES OF IVY; and the effect produced is at once beautiful and striking. Some are more robust growers than others; some are variegated, almost white; others of the deepest richest green; and the combination and contrast enhances the beauty of all. Most of the growth now reaches the eaves, so that the wall is almost hidden by this lovely draping. The inquiry suggests itself, Why on rural buildings to which it is so much more appropriate, enduring and beautiful than paint, this natural covering is not more frequently resorted to? and why in cities the naked walls of churches and other public and private buildings should not be thus adorned and protected?

— To the many inquirers seeking information HOW TO DYE MOSSES, GRASSES, AND FLOWERS, the following mode as adopted in Germany may be useful:—

*To Dye Moss Green.*—Boil half a pound of alum in four quarts of water, and dissolve half a pound of finely triturated mineral blue in it, and a dark green dye is the result. Or a very beautiful green dye may be made with indigo—carmine and picric acid, adding water to reduce it to the desired hue. As picric acid is rarely to be had of uniform strength the exact proportions cannot be given. The same dye may be used for Grasses.

*Black.*—Two ounces of logwood in one quart of water, quarter ounce of alum, and 3 ozs. of copperas, the whole boiled together and the moss dipped into it while hot. Or two parts of logwood and one of fleabane thoroughly boiled together, and a little green vitriol.

*Red.*—The best way to make this colour is to boil as much red aniline in rain water as will produce a pretty red. The dye should be hot when the moss is dipped.

*To Bleach and Dye Everlasting Flowers.*—*Bleaching.*—Put a number of flowers, which have previously been placed in a warm chamber to cause them to open, in a vessel containing a solution of chloride of lime, half ounce of soda, and two quarts of water. Cover the vessel and leave it as it is in a moderate temperature for four or five days. During this period the flowers first change to an orange colour, and afterwards to a bluish-white. As soon as these changes show themselves take the flowers out and pour off the fluid, and fill it up again, using this time only 1 oz. of chloride of lime and no soda. Let the flowers remain in this until quite white, subsequently drying them in a warm oven.

*Dyeing.*—*Carmin.*—Quarter loth (about two drachms) of Munich lac, quarter pint (about half drachm) ultramarine blue, dissolved in 12 loth (about 6 ozs.) of warm water. *Rose.*—Quarter quint of extract of safflower, dissolved in one quart of cold water. *Dark blue.*—One loth indigo extract in a quart of water. *Cornflower blue.*—Half loth of blue aniline, two loth spirits of wine, in one quart of water. *Violet.*—Half loth violet aniline, with the same proportions of water and spirit. *Light blue.*—Half loth Prussian blue, dissolved in a quart of water. *Dark blue.*—One loth of catechu, boiled in a quart of water. *Light green.*—Quarter loth picric acid, and quarter quint of indigo in twenty loth of alcohol. *Black.*—As given above. *Orange.*—Three loth of borax in 2 quarts of hot water, leaving the flowers to steep for some time.

The dyes for Grasses, &c., are made in the same way.

### ROSES FOR FOLIAGE.

I WISH to grow five or six Roses with handsome foliage simply to pick leaves from. What sorts would you recommend, and what is the best mode of pruning? If I had several free-growing varieties of different types I could nearly always match the leaves with the flowers, at least quite near enough for drawing-room purposes.—KITTY.

[To supply fine foliage in making up bouquets of Roses we would recommend to be grown a small hedge of the old Hybrid Bourbon Céline, which has pretty pink flowers with abundant and magnificent foliage.

As Roses suitable to grow for the same purpose we would mention Charles Lefebvre, H.P., much resembling Céline in foliage; Eugène Appert, H.P., for the darkest green foliage; Boule de Neige, H.P., with pretty wavy chocolate-tinted edges to its young foliage; François Michelon, H.P., has fine foliage of a lighter green. Climbing Devoniensis, Tea-scented, with fine dark foliage, and Rêve d'Or, Noisette, with rich abundant

foliage, are both good to grow for foliage for these families. Coupe d'Hébé, Hybrid Bourbon, has fine, fresh, plentiful foliage. All the foregoing varieties grown for this purpose will require little pruning, cutting out the old wood will nearly suffice.]

### THE BRIGHTON SUMMER SHOW.

LOVELY weather, numerous entries—the majority of which proved meritorious—a crowded company, &c., rendered this Show a perfectly successful one. It was held at the Royal Pavilion for the twenty-fourth time on Wednesday last, and remained open till the evening of Thursday. A show extending over two days may be objectionable if it is devoted solely to Roses, but when, as in this instance, it embraces plants and fruit in addition to cut flowers, and is held in so large a town as Brighton, a second day—"a people's day"—with a low rate of admission, not only affords a treat to those sons and daughters of toil with whom the expenditure of every shilling is a matter of no light importance, but is really a profitable investment from a financial point of view.

The Exhibition, filling five rooms and a large tent, was of considerable excellence both as regards the collections shown and the skilful and tasteful manner in which they were arranged. Take, for example, the Banquet Hall, in which the Roses in competition for the Ashbury cup were staged; the 648 trusses of Roses brought together in contest for this the premier prize made the centre and front of the hall gay with colour, which was agreeably relieved by magnificent groups of Palms and fine-foliaged plants at each end. In the Music Saloon, too, a pleasing effect was produced by placing table decorations and artificial flowers in the centre and front of the room, with groups of Ferns arranged along the walls. The management of the interior of the tent afforded further proof of the sound judgment and good taste of the Superintendent, Mr. E. Spary, for here all the gayest flowering plants gained an additional charm from the subdued light which the tent afforded. We will now turn our attention to the collections, beginning with the

ROSES.—Here Messrs. J. Mitchell & Sons, Piltown Nurseries, Uckfield, were placed first, winning the ten-guinea cup given by James Ashbury, Esq., M.P., with seventy-two trebles of great excellence. The most striking characteristics of their collection were the large size yet compact form of the flowers, combined with brightness of colour and an air of freshness that was very charming. Of course every individual flower was not quite first-class, but there was certainly nothing like a bad flower among them. The most notable were Souvenir du Champ de Mars, a splendid crimson variety; Paul Verdier, in capital form and condition; Marie Baumann, one bloom of this being especially fine; Madame Pulliat, a brilliant scarlet kind of fine form; Clotilde Rolland; François Michelin, very fine; Duchesse d'Aoste, a charming light pink; Marquise de Castellane, three magnificent trusses; Xavier Olibo, Madame de Ridder, Baroness Rothschild, and Alfred Colomb—a select dozen of sorts old and new, which as shown here by Messrs. Mitchell it would be difficult to match. It may be well to note here that a detailed Rose list is not contemplated in this report, and the few kinds noticed may be regarded as the cream of those exhibited. In other stands were excellent flowers of Madame Lacharme, not very large, but good both in form and colour. Antoine Ducher, Maurice Bernardin, Devienne Lamy, Alfred Colomb, was good in several stands, and notably so in one by Mr. Piper, nurseryman, Uckfield, who also had fine blooms of Paul Verdier, Richard Wallace, La Fontaine, and Mdlle. Thérèse Levet, a charming pink kind. Mr. Knight of Hailsham had excellent examples of Fisher Holmes, Duc de Rohan, and Exposition de Brie. A stand of trebles exhibited by Mr. W. Lacy, gardener to C. T. Mortimer, Esq., Wigmores Park, contained three of the finest examples of Marie Baumann I have ever seen, very large in size, close and compact in form, and bright in colour; they were certainly worthy of especial notice, but unfortunately the stand took no prize, as the other Roses in it were not so meritorious.

PLANTS.—The first prize for ten variegated and fine-foliaged plants was well won by Messrs. Balchin & Nell, nurserymen, Hassocks Gate, with a fine group very well arranged. A Chamærops, an Encephalartos, and a Latania—all fine plants, and well matched as to size—formed a central triangle, around which swept a semicircle composed of Croton variegatum in fine colour, a noble specimen; Pandanus Veitchii, Croton majesticum, Yucca aloifolia variegata, Croton Veitchii, Dracæna australis, and Croton angustifolium. There were some good plants in the second-prize group, a Dracæna Shepherdii being worthy of especial notice from the stately and striking appearance which it presented. In Fuchsias Messrs. Balchin & Nell were again first with fine plants of pyramidal form, and about 6 feet high. It was to be regretted that flowering Begonias were not better represented. The only really good specimen of this most useful class was our old favourite B. Weltoniensis. Some of the Ferns were excellent examples of skilful culture.

Mr. Meachin, gardener to E. Armstrong, Esq., and Messrs. Balchin & Nell taking the first places in two classes, the first having good plants of Asplenium nidus, Lygodium scandens, and the charming little Adiantum gracillimum; and the other a grand Woodwardia radicans, a magnificent specimen with fronds 4 or 5 feet in length and of proportionate width; Davallia pyxidata, and Cyathea medullaris. The plants in the tent consisted principally of stove and greenhouse plants, with zonal and fancy Pelargoniums. The latter were especially good, a perfect mass of bloom, reflecting much credit upon Mr. W. Miles, by whom they were exhibited. The zonals by the same grower were excellent plants in fine flower, but there was rather an unnecessary display of stakes. The most notable kinds were Kisber, a rich scarlet of fine form; Maréchal Vaillant, orange scarlet; and the bright pink Rose of Allendale. Messrs. Balchin & Nell were an excellent first with eight stove and greenhouse plants, all fine specimens, the best being a Bougainvillea glabra, 5 to 6 feet high, and nearly as much in diameter, laden with its mauve-coloured bracts; a Stephanotis, equally good; Erica Paxtoni, very fine, and a grand plant of Kalosanthus coccinea. Mr. Meachin, who took second honours, had capital examples of Vinca rosea and Allamanda Hendersoni.

DINNER-TABLE DECORATIONS.—These offered nothing new, nor was the contest a severe one, Mr. and Mrs. C. Burley of Brentwood easily taking first honours in all three classes. The leading colours were white, pink, and blue, intermingled with sprays of Grasses and Ferns. Most of the stands were of the Marsh pattern, or modifications of that elegant form. The tenacity with which exhibitors cling to one form of stand is a remarkable instance of the general tendency to run in a groove, and yet in actual practice the same set or pattern of stands is never used on consecutive nights; but, on the contrary, a change of stands, colours, and style of arrangement is required every night, no arrangement or part of an arrangement being admissible twice in the same week. Why, then, do we not find this better illustrated at our horticultural exhibitions?

Near the table decorations was an attractive display of wax-paper flowers, to which a first-class certificate was awarded. They were exhibited by Mr. Snelling of the Chain Pier Bazaar, and were of the highest order of merit. Plants of Dracænas, Caladiums, Gloxinias, and Mignonette, and flowers of Orchids, Roses, and many stove plants being copied so faithfully as to entirely deceive one.

The prizes for miscellaneous cut flowers brought together a most attractive collection. Among the most beautiful a cluster of the deep scarlet rosettes of the Pomegranate was very conspicuous; another of Desfontainea spinosa, the long, rich, scarlet tubes tipped with yellow mingled with the dark green holly-like foliage was very charming; Begonia nitida, the white flowers tinged with a delicate shade of pink was very lovely; Bougainvillea glabra, effective as it is, was never more so than in such a collection; then came Bouvardia Vreelandii with its lovely small white clustering flowers, the striking white spikes of Swainsonia grandiflora, the delicious Tuberosa, the magnificent Carnation Souvenir de la Malmaison—the white flowers slightly suffused with pink are so fine as not unfrequently to be mistaken for Roses when cut; the old but very charming Bouvardia jasminoides, the orange-coloured Izora amboynensis, and Statice profusa with dense clusters of lovely blue flowers. There is nothing very new or novel among these few select kinds, but they are some of the very best flowers in cultivation for decorative purposes.

FRUIT.—Black Grapes were well represented by many bunches of good size, capital colour, and fine large berries, both of Black Hamburg and the more choice Muscat Hamburg. Muscat of Alexandria was shown large in bunch and berry, but sadly deficient in colour, which was much better developed in some Buckland Sweetwaters. Of Strawberries the first prize fell to that excellent sort Dr. Hogg in both classes for single dishes, Sir C. Napier coming second in both instances. These with a dish of the dark-coloured Empress Eugénie shown in the collections were the only really good Strawberries in the Show, the whole of the fruit in the other dishes being so small as to be more suitable for preserving than for the dinner-table. A few Melons, Peaches, Nectarines, and a Pine or two were also exhibited, but none of them call for especial mention.—E.

### TABLE DECORATIONS AT THE AQUARIUM SHOW.

It would be a calamity if what one hears be true—that table decorations are going out, and that the upper ten especially are setting their faces against them. There are indeed indications that the thing has been overdone, and the trouble and expense connected with it has somewhat sickened people. Few persons except those who have tried it know how much is involved in it; and if the mistress of the house could delegate these things to a servant it might be very well, but not one servant in a thousand has correct ideas of taste—indeed many,

very many, ladies have odd notions on this subject—and consequently either she or some of the younger members of the family undertake it. Now when one considers what was involved in table decorations—the elaboration of detail, the mass of flowers, and even the displacement of the tables themselves—it was not to be wondered at that an *enquete* on the subject should break out, and that two or three hours for this one object was rather too much. Hence if anything can prevent this calamity it must be by maintaining a simpler but equally effective style of decoration; and this is, I conceive, what the judges at a show are bound to consider, and what was considered in the judgment at the Show at the Aquarium. When one hears the visitors exclaiming, "Well, I really don't see much in that; I wonder why it had the first prize," it is always to me a hopeful sign of the judging being correct, for the mass of visitors like to see gorgeous display, and, as the poor people say of the doctor, to get something for their money be it even a nasty black draught. With these views, and judged by the test of simplicity and effect, let me offer a few remarks on the principal exhibits on the occasion referred to.

The first prize was awarded to Mrs. Burley for a very elegant arrangement; the centre being a Palm, round the base of which were grouped some fine blooms of Cattleya and other Orchids and Fern leaves. At either end were two trumpet glasses, which to my mind would have been better had they been a trifle smaller: these were tastefully arranged with Rhodanthes, Grasses, and light airy flowers, while the climbing Fern was twisted round these. The fruit was in glass dishes, and consisted of Apricots, Figs, Peaches, and Grapes, with a Pine and Melon at either end, specimen glasses being placed among the fruit. Strong-smelling flowers had been avoided, and altogether it thoroughly deserved the position it took. Mrs. Cypher of Cheltenham took the second prize with another excellently arranged table. A modified March stand occupied the centre, having a trumpet-shaped glass at top, in which was a single bloom of the singular and beautiful *Gloriosa superba*, sprays of *Oncidium*, Grasses, &c. The base was perhaps a little too formal and required to be broken up with foliage, Ferns, &c. At either end were stands with a triple glass, in which the flowers were arranged somewhat similar to the centre one. Peaches, Nectarines, Grapes, Pine and Melon were the fruits arranged in flat glass dishes, and specimen glasses introduced amongst them. Mrs. Harris took third prize. The stands were upright glass ones with cornucopias suspended from them. Here *Rhodanthe* was too profusely used, the upper glass containing hardly anything else. The fourth prize fell to Mrs. Soder, whose table was decorated with three March stands, arranged with Ferns, and calling for no particular observations.

Amongst the unsuccessful ones Miss Edith Blair's deserves notice. It was very elegantly arranged but meagre, no fruit being placed upon the table except at the bottom of the central Palm. This was a grand mistake. When the fruit was taken away, which it must be if any of the guests were to partake of dessert, the table would look still more meagre; and I am persuaded it is a great mistake to mix flowers and fruit together. Messrs. Dick Radclyffe & Co. exhibited a very grand table, but unhappily too crowded for its size and the number of guests. It was highly commended by the Judges as suitable for a large table; and in some of the others were notable instances of how *not* to do it.—D., Deal.

## THE RESTING SPORES OF THE POTATO FUNGUS.

THAT a large number of animals and plants are in the habit of passing the winter months in a state of seclusion and sleep has been known from very early times. The facts regarding the curious phenomenon of hibernation are best known amongst the larger animals, where the observations are easiest made. Nothing can be more curious than the disappearance of the bear for five or six of the winter months in drifts of snow. During this period the great beast remains in a state of lethargy, and though taking no food yet remains in condition. A mechanical contrivance is provided for the intestines, and when the spring sun once more sheds its life-giving rays upon the wintry earth the bear returns to renewed activity.

There are innumerable contrivances in nature which will suggest themselves to every reader, by means of which the vitality of animals and plants is preserved during the winter months. The seed of the annual with its protective integument, the fleshy subterranean rootstock of the perennial, the egg of the insect, the spawn of the Mushroom, and the resting spores of many fungi.

Of course the smaller the seeds, the threads of spawn, and the spores are, the more difficult are they to make out. No one can now be found to deny the meaning of the egg of the bird, reptile, or insect, because these objects are visible to the

unaided eye and have been repeatedly observed. Their meaning is known to all; but the egg condition of a minute fungus like the one which causes the Potato disease is so small that it takes the higher powers of the microscope to see it; it is therefore extremely difficult (when once obtained) to watch and keep alive. In known eggs, like the eggs of the hen, the snake, and the spider, the length of time which must elapse before the young animal emerges is known; but in the egg of the Potato fungus this period, like the egg itself till quite recently, remained wholly unknown. The Potato fungus is only seen in a flourishing state for a few weeks in autumn, it then suddenly appears in our Potato fields, destroys our crops, and vanishes. Last autumn I wrote a paper for the *Journal of Horticulture*, explaining how I believed the Potato fungus carried a large number of eggs or resting spores, and produced within the tissues of the leaves and amongst the cells of the tubers. These eggs had been suspected and searched for in vain by many botanists for many years. De Bary, the famous botanist of Strasburg, writes that he has searched for these resting spores for fifteen years, and on every opportunity he says he has "searched for them in the stalks, leaves, flowers, fruit, and tubers of the Potato." The Rev. M. J. Berkeley, however, with a keen insight into the true nature of the Potato fungus, made a suggestion many years ago that the true resting spores had very probably been once seen, and even illustrated, although the author himself (Dr. Montague) did not understand their meaning. It appears that a Dr. Rayer about, or previous to, 1845 found spherical bodies in spent Potatoes, and these bodies Dr. Montague illustrated. Being new to science, and consequently nameless, Dr. Montague christened them *Artotrogus*. Mr. Berkeley subsequently said that he believed this rare *Artotrogus* to be no other than the egg state of the Potato fungus; but from 1845 till last year no one could ever again find one or the other, so that Mr. Berkeley's view was obliged to remain a mere surmise. Like De Bary and many other botanists I have long and almost hopelessly searched for the egg state of the Potato fungus. This search had invariably been without the slightest result till last July. The readers of the *Journal of Horticulture* will remember how I kept infected leaves and tubers damp, and how in the damp portions of the magma I had the great pleasure of at last seeing the long-lost *Artotrogus* growing upon the threads of the *Peronospora*. This fact confirmed the correctness of Mr. Berkeley's original views to my own mind, but the unfortunate thing about it was that I could hear of no one else repeating my experiments with the same results. During the months of April and May last it, however, came to my knowledge that Mr. C. E. Broome, one of the best and most exact botanists in this country, had experimented with Potato material as suggested by me, and had obtained *Artotrogus* in abundance as I had obtained it. This was a most fortunate circumstance for me, as my resting spores had now been sleeping so long that some persons began to think they would never wake up again. The sleep had indeed been long, but as there is notoriously no road without a turning of some sort, so my resting spores at last ceased to rest, and then reproduced the fungus of the Potato disease.

The resting spores were obtained late in the summer and in the early autumn of last year (1875) both by Mr. Broome and myself, by keeping infected Potato material constantly and uniformly moist. Mr. Broome maintained his bodies alive by simply keeping the old leaves in a slanting saucer in which was a small but constant and uniform supply of water, and the whole kept under a bell-glass. I was afraid of putrescence, mildew, and infusoria, so kept my last year's materials in sealed bottles either with a little water or with expressed juice of horse dung diluted with water. In these bottles most of my resting spores have retained life. I have kept my Potato mash free and under darkened bell-glasses since last April, and no foreign parasites to any damaging extent have appeared. Before germination most of the resting spores grew considerably in size, many attaining four times their original bulk.

The accompanying illustration, fig. 6, is an attempt to show the nature and habit of the Potato fungus, principally in its resting condition. All readers of the *Journal of Horticulture* probably know that plants when viewed under the microscope are seen to be built up of minute cells or bladders, the cells adhering by their outer surfaces like bricks in a wall or cells in a honeycomb. This bladdery structure is more or less supported and strengthened by numerous springs or spiral vessels. The minute springs are shown at A, with the resting spores of the Potato fungus within the threads of the springs. The

cells or bladders are shown at the base of the hair at *e*, the cells of the skin of the leaf at *c*; the latter have an irregular outline, and fit one into the other after the manner of the bones of the skull. At *d d* may be seen two slits in the skin; these slits are the openings by which the plant breathes. The moisture within the plant pours out through these slits in the

Fig. 6.—THE RESTING SPORES OF THE POTATO DISEASE FUNGUS (*Peronospora infestans*) enlarged 400 diameters

form of vapour, and there are a hundred thousand or more of them to every leaf. The tall body at *e e e* is one of the hairs of a leaf built up of three cells, like one chimney pot on the top of another. The Potato fungus commonly traverses by its spawn the interior of the leaf; as a rule it pushes itself between the bladdery interior cells, and emerges to the light

through the hundreds of thousands of breathing spores (D D) of the leaf. The common form of the fungus is seen emerging through these breathing pores and producing its fruit at F. This fruit at a certain period of growth exhibits the marks as shown on the cut; these marks are similar in character to the lines seen on water when it begins to freeze. Later on the fruit or spore bursts into about six, seven, or eight portions, and each portion soon acquires two tails as seen at G. These latter tailed bodies are the zoospores, for, though vegetable in nature, they swim about by their two tails like animals, and often float again into the very same breathing pores from which the thread which bore them only shortly before emerged. Dew, mist, or rain supplies the moisture in which they float on the leaves. Now, wherever these zoospores germinate they at once (by poisoning the material of the plant) give the Potato the murrain, and the experiment which proves it has been repeated many times and by different competent observers. As the healthy Potato will always take the murrain from these spores as certainly as a healthy man will take the small-pox when inoculated for that disease, it is reasonably considered by botanists that the Potato fungus will cause the disease.

The various dark circular bodies seen in the illustration are the mature resting spores of the Potato-disease fungus as obtained by me from the Chiswick Potatoes last year. At first they were carried on threads and were semi-transparent and much smaller in size, and in this latter condition they were illustrated for the *Journal of Horticulture* last summer. They arose, as is there stated, by a male anther-like body attaching itself to a female stigma-like or pistil-like body. From this contact arose the eggs or resting spores of the Potato fungus. During the months of May and June last most of these resting spores germinated. The first sign of renewed life was the cracking of the outer skins as at H H, just as the skins of some seeds crack prior to germination. An inner bladder was often expelled as at J, and this bladder may be seen still inside the resting spores at K K K K. This bladder in its turn frequently cracked to pieces and set a number of tailed zoospores free exactly similar in character with the zoospores produced at F, and one of which is seen free at G. On being placed upon slices of Potato and upon Potato leaves they at once grew, corroded the cells of the plant, and reproduced the murrain. Other of the resting spores, as shown at L, L, L, L, did not produce zoospores, but instead of these bodies they showed the spawn coiled up worm-like within. When the outer skins of these latter resting spores cracked the spawn unwound as at M, emerged and got free as at N, and exhibiting a joint at O produced the fungus of the Potato disease terminal as at P.

Now, although these phenomena are described in a very few words, they represent a whole year's harassing, anxious, thankless work. As I did not know whether the resting spores intended to sleep for ten days or ten months, I was under the necessity of constantly watching them. Everyone knows how a batch of apparently healthy seeds may on germination all damp-off and die, and how to avoid this different soils, temperatures, and conditions must be tried by seed-growers. In the same way I divided my material, and to avoid any chance of failure got the resting spores to grow under every condition of which I could think. They grew remarkably well under most of my conditions, the best being, probably, expressed juice of Potato leaves upon moist fragments of clean broken flower-pot and in diluted expressed juice of horse dung upon similar fragments, always kept moist and shaded under darkened bell-glasses. Most of my conclusions (and all the really critical ones) have been confirmed either by the Rev. J. E. Vize, Mr. C. B. Plowright, or Mr. C. E. Broome. A strong attempt was made last year to connect my resting spores with one of the Saprolegniæ (as they are termed), fungi commonly found upon decaying insects in water, and because I illustrated my spawn threads with joints an equally strong objection was taken to these jointed threads because the insect fungi have threads without joints. But my spawn threads were correctly represented as jointed; the Potato fungus has jointed threads, and one of the resting spores which germinated displayed three joints. On sending the mounted preparation with the drawing to Mr. Berkeley for confirmation he replied, "I found the germinating oospore exactly as you figure it. There can be no doubt about the matter." There is a second fungoid pest of Potatoes named *Fusisporium solani*. This pest, says Mr. Berkeley, "causes rapid and loathsome decay, especially when in company with the *Peronospora*." It generally is in company with it, and the two marauders were together last year at Chiswick, and in attempting to bring down the *Peronospora* I

shot both birds with one charge. The fruit of the *Fusisporium* is shown on its thread at Q. The fruit has three joints, and so each fruit commonly produces four new plants; but during my experiments I have observed that certain fruits instead of germinating at once round themselves off into spheres as at R, R. These spherical bodies then go to rest for about two months, when they burst as at S and at once renew the species. So that under favourable circumstances we get six resting spore generations of *Fusisporium* and one of *Peronospora* every season.

I have maintained the resting spores of both fungi in vigorous health—1, in old decaying Potato leaves kept moist; 2, in scrapings of the tuber kept more or less water and damp air; and 3, in diluted expressed juice of horse dung. I have not the slightest doubt in my own mind that the resting spores of both the above-described pests naturally abound every year in myriads in old moist Potato refuse, especially when it is allowed to remain about ditch sides, damp places, and dung heaps, and from these situations and upon the ground the Potato fungus first grows, and there the disease springs every year.

Since my observations were printed last year many papers have been published on the same subject, and some botanists have obtained an organism similar in some respects with mine. De Bary's plant may be taken as a general type of all. It is called a species of fungus new to science by De Bary under the name of *Pythium vexans*, and I have engraved it at T to the same scale as the bodies observed by me. De Bary does not claim his plant to be the same with mine, although a suggestion to this effect has been made elsewhere. De Bary's plant is much smaller than mine, and has continuous threads without joints; my plant is carried on jointed threads and produces a resting spore which sleeps for ten or eleven months before germination. De Bary's plant has no true resting spore. My plant grows upon and appears to be peculiar to Potatoes, whilst De Bary's only produces fruit or dead insects.

When the habit of a disease is fully known a cure or palliative ought to be forthcoming, unless the disease is incurable. There seems to be no reason why something should not be done with the Potato disease, especially after what has been done with the disease of the Vine and other plants, but just now any suggestion for remedial treatment must be premature.

When my first notes were published I attached very little importance to them, and I had no settled intention at that time of carrying my experiments any further. As my observations were, however, seriously challenged in different quarters I thought it better at extreme inconvenience to myself to watch the bodies discovered by me in the Chiswick Potatoes through an entire year. The result is now before your readers. If no one has seen these bodies before it is simply because they have not looked for them in the right place and in the right material. That the resting spores are produced in millions in decayed Potato material there can be no manner of doubt, and as Mr. Broome has also obtained the same results I do not stand alone.

The work to be taken in hand now is to prevent the formation of the resting spores, or if formed to destroy them. If these bodies are once killed Potatoes will not suffer much from the ordinary spores or the "perennial mycelium" in the tuber pointed out by Mr. Berkeley in 1845.—WORTHINGTON G. SMITH.

### SYRINGING.

HAD "W. J. B." reserved his opinion until in possession of all the facts, it might have been different to that given at page 466. Your correspondent states, "that even in nature if the rain could reach the under sides of the foliage of trees it would often be of great benefit;" but "if we follow nature," writes "W. J. B.," "we find that during showery weather vegetation is freer from insects than during a time of drought." This is clearly not because it "rains upwards," but is effected by the action of the water upon the upper surfaces of the leaves. "W. J. B." instances two Rose trees which he experimented upon by syringing one regularly and not syringing the other, and in one case he had "healthy foliage and fine blooms," in the other "thousands of insects"—only what might have been anticipated. His Rose evidence shows neither the necessity, or otherwise the value, of syringing the under side of the leaves. "The water was applied to the under side of the foliage, but it did nothing but good." Decidedly, no injury could follow; but would not the result have been equal had the other Rose had distributed over its head a like quantity

of water? The good resulting of "the water applied to the under side of the foliage" might be, and no doubt was, due to the water moistening the soil for a distance around the plant at least equal to the spread of the head. The water would feed the roots, cool the heated tissues, and have a mechanical action in freeing the foliage of dust and insects.

There can be no objection to syringing plants overhead with "pure clean water," but collected water is often anything but that; and I repeat that when moisture in sufficient quantity is afforded the roots and atmosphere, the necessity for syringing Vines and other subjects (which from their position can only be done on the under side of the foliage), does not arise, and is in all cases of sedimentary matter following, syringing is more calculated to injure than benefit. I applaud the right use of the syringe as much as I deplore its abuse, but I am satisfied that there is much thoughtless and unreasonable squirting in vineries and other glass structures.—G. ABBEY.

### THE WAY TO GROW HAUTOBOIS STRAWBERRIES.

I DARE say some will say, "I knew all about growing Hautbois Strawberries before." If so, why did you not tell me? For I have asked more than once for information on the subject in this Journal, and scores of times verbally, in fact of everyone I met who I thought likely to know anything about it. True, I have not been short of advice of one sort and another. One adviser said I had not the right kind, another that the soil was wrong, a third that I gave too much manure, and a fourth that I ought to give more. Others recommended cutting off the tops, and others growing the plants from seed.

I changed plants, soil, aspect, and treatment all to no purpose. I had plenty of foliage, flowers, and fruit such as it was, but the greater portion of it was undersized and perfectly dry and hard. Perhaps three, or sometimes half a dozen, fruits would swell off on a plant, and I could scarcely gather a dish of fruit at a time from a large patch. When I did manage to pick a tolerably good dish it was very highly commended, and my employer expressed a wish for more. I have been obliged to admit more than once that I did not know how to grow them—rather humiliating this to one who has given his life to this and kindred subjects.

Speaking one day to a neighbouring gentleman about Strawberry growing, he informed me that he used to have Hautbois Strawberries in abundance without any special cultivation; that they, in fact, grew in an almost wild state on the site of an old ditch, and I believe he added that since those plants were removed his gardener had not been able to do much with this kind of fruit. I at once attributed his former success to moisture and shade, and secured both for my plants during the following season, but the result was the same as before. Now I am happy to say I have found out the secret. A portion of my plants last summer were left without any trimming, the runners being allowed to remain where they rooted naturally, and the result is that on these runners there is one of the greatest crops of Strawberries I ever saw, and all the fruit swells off to a good size. There is hardly a fruit on the old stools from which the runners proceed; and the plants kept clear of runners according to the orthodox method of Strawberry growing are, as they ever were, almost fruitless.

Now I know what to do. Hautbois Strawberries in future will be planted 3 feet from row to row, early runners will be encouraged to root in the space between the rows, and the old stools and surrounding soil dug clean out every season and replaced with fresh rich soil for the encouragement of another succession of runners. Heavy loam liberally treated is the best soil for this and all other Strawberries, excepting President and perhaps the Alpines.—WILLIAM TAYLOR.

### EXHIBITORS' WRONGS.

WHEN I first wrote to you to denounce two-day Rose shows I mentioned that exhibitors obtained no redress if their boxes, &c., were injured or lost on the return journey; but I was not then aware that such a case as the following was possible. On Wednesday and Thursday, July 5th and 6th, I exhibited at the Westminster Aquarium. One of the classes in which I staged was the open class for twelve varieties. Boxes could not be removed except between a late hour on Thursday evening and 10 A.M. on Friday morning. A friend of mine engaged to remove my boxes and arrived at 9.30 A.M. on Friday. Not only was the cover of the box exhibited in the open twelve gone, but more than half the tubes as well. For

a week no notice was taken by the Manager either of my letters or of four visits paid by my friend. I am now coolly informed that the articles have been looked for and cannot be found. That is to say, unless I go to the expense of legal process there is no redress. Have any other exhibitors suffered similar losses?—T. H. GOULD, *Mortimer*.

### ROSE SHOWS—ROSE ELECTION.

THERE is an error in your otherwise (I am proud to think) truthful report of the Maidstone Rose Show. It is with regard to the class for thirty-six varieties, in which you say there was no competition. There was keen competition, the prizes falling to the same exhibitors as those for forty-eight trebles, and in the same order—viz., Messrs. Paul & Son, Mr. Cant, and Mr. Turner. I should like to avail myself of this opportunity to endorse (which our lately purchased experience I regret enables me to do) all that your correspondent wrote a few weeks ago about Rose shows financially. It is a fact that in this town of nearly thirty thousand inhabitants ("D., Deal," was too lenient in giving eighteen or twenty thousand as our number) we only took £1 for every thousand. I think we shall not spend our money in a vain endeavour to attract the public next year.

May I say one word about the forthcoming election? It is with regard to the "best stock for Roses." I venture to doubt the utility of recording the opinions of Rose-growers upon the question, seeing how entirely the choice of a stock depends on the soil. Would not the experience of growers as to the particular stock which suits each Rose be more useful? and by taking the aggregate of votes for each stock the idea of Mr. Hinton would also be carried out. The letters B., S.B., M., or O for Briar, Seedling Briar, Manetti or Own root, might be annexed to each Rose according to its partiality for one or the other. Let those who would omit the "O" try Charles Lefebvre, Camille Bernardin, and one or two others I could name, taking strong plants and cutting back very hard.—HUBERT BENSTED.

### PEACH BLISTER.

I AM quite ready in the friendliest way possible to supply a few "facts and not fancies" on this subject. For instance, at the earliest stage of blister, and when the Peach leaf first begins to show signs of discoloration and thickening, the spawn of *Ascomyces deformans* exists and can be seen within the leaf. This fact has been repeatedly observed and confirmed. Again, the spawn within the leaf at this early period excites the growth of the plant, destroys the chlorophyll, and greatly and irregularly multiplies in number and enlarges in size the constituent cells of the leaf: hence the enlargement and thickening. It is a fact that the fungus spawn causes this, and commonly causes similar phenomena; but the statement that the east wind can do these or similar things must be put down as a mere fancy. When the leaf is enlarged, the interior corroded and the blister formed, the disease still progresses, and now bursting through the cuticle it lives on the outside instead of the inside of the leaf. I maintain that it is only a fancy to suppose from this observation (which cannot be denied) that the fungus has only latterly established itself upon the blister. The fact is, as I said before, that, though unseen, the fungus primarily caused the blister when inside the leaf by enlarging, increasing, and corroding the cells. This condition of the leaf is illustrated by me in a drawing now exhibited in the Kew Museum. It is a fact that the spores of the fungus of the Peach blister will only grow on the Peach and its immediate allies, and when the spores do germinate they at once repeat the phenomena recorded above quite irrespective of wind, whether north, east, south, or west. On the strength of the above-recorded facts it is reasonable to believe that *Ascomyces deformans* certainly can be, and is, the cause and not the result of Peach blister.

I have no desire to be mischievous in my endeavour to record observations which I believe to be facts, and I know well (as does everyone else), that cold searching winds will throw plants out of health and injure their foliage, but it is a mere fancy to suppose the east wind will or can cause the known phenomena of Peach blister. The wind which carries so many diseases may very possibly carry the spores of *Ascomyces*. It must surely also be the record of a mere fancy, and one, too, of the most transparent kind, of Mr. Luckhurst's when he writes, "Mr. Smith evidently confounds blister with

curl caused by aphides." In answer to Mr. Luckhurst's challenge, I have stuck throughout to the true blister of Peach leaves as caused by the fungus, and distinct from injured leaves as punctured by insects or damaged by bad weather. I know all conditions of the leaves equally well.—W. G. SMITH.

To Mr. Smith's statement, that Peach blister "often occurs with great virulence inside the most carefully protected houses," I can only reply that I have never seen it in such houses, and I have been intimately connected with Peach trees for a quarter of a century. I have seen Peach blister under glass, but never when the foliage has been "carefully protected," the evil in every case coming under my notice having been directly traceable to careless ventilation or the sweeping of the wind through crevices.

Mr. Smith speaks of "one form" of blister, but the blister which is such a terror to gardeners, ruining their crops and frequently their trees, is—according to the experience of Mr. Luckhurst, Mr. Taylor of Longleat, and Mr. Taylor of Hardwicke—caused by the extreme cold of spring, and is preventable by the protection afforded by glass or canvas. That is also my own experience.

If the blister were caused by fungus it is not preventable by protection, but I cannot permit such a dogma of despair being established without recording my protest against it.

The Peach blister which gardeners have to combat is preventable. If means of protection are afforded and are applied we should have fruit where we have barrenness, and healthy instead of unhealthy trees. That is the great object which is sought for, and which is attained by those who carry out that practice.

I have frequently seen the curl under glass, but seldom the blister, and I cannot help thinking that Mr. Smith has confounded the two evils to which the Peach tree is subject.

I am not surprised that a paragraph recommending the daubing of the wood in winter to prevent blister affecting the leaves which appear three months afterwards should have been smiled at by some and confuted by other practical men, for the practice is an old and exploded one.

Science has done much for gardening, and Mr. Smith is a most industrious and successful investigator of matters hidden from ordinary observers; but however necessary the microscope may be to reveal the first cause of a malady, it is not necessary to show the remedy for Peach blister, for that remedy is glass in spring to protect the foliage, and not "lime, soot, and sulphur" besmeared over the wood in winter. It is only fair, however, to note that Mr. Smith does not advocate daubing.

The loss of even one crop of many a Peach tree is as costly as would have been the glass to cover it, and the good effects of the protection are permanent in securing blister-proof trees and full crops of fruit in after years. Daubing the trees in winter may do no harm, but it certainly cannot prevent blister, even were it caused by fungus, but efficient protection is a certain remedy of the evil complained of. This I have proved repeatedly, and am fortified by the successful practice of many able gardeners.—A SURREY GARDENER.

### THE GLASTONBURY THORN.

This mysterious shrub or tree, which in the middle ages was an object of sacred interest, is now chiefly interesting on botanical reasons. I believe it has not been referred to in print for some time, but a correspondent of "Notes and Queries," who signs himself "J. B.," gives an account of a recent visit to Glastonbury Abbey. Loudon, in his "Arboretum Britannicum," mentions the early-flowering or Glastonbury Thorn under the name of *Crataegus oxyacantha præcox*, stating that the variety comes into leaf in winter, and the flowers following speedily, it may be, occasionally in mild seasons, in flower at Christmas, according to the legend. And he had ocular evidence of the fact, as he had specimens sent him from Glastonbury in 1833 and 1834 during December, the branches having on them flowers and ripe fruit also, the latter, of course, produced from flowers of the previous May. He found, on inquiry, that plants at Loddige's nursery and in the gardens of the Horticultural Society would occasionally flower in the winter, and at other times in the early spring. The traditional story, which is pretty generally known, is that the original tree was the staff of Joseph of Arimathea, who, coming to Glastonbury, drove his staff into the ground in winter, when it at once put forth leaves and blossoms, continuing to do so at the same season, a tale which brought some profit to the monks.

"J. B." states—"The tree shown to me was a young tree, probably about fifteen years old, and to my surprise I found it with a great many double blossoms opened on April 19, which is a full fortnight or more in advance of the very earliest Hawthorn in the Regent's Park." This, however, is nothing very remarkable, but he was assured by a man in charge of the Abbey grounds that "it invariably blossomed twice a-year, once at Christmas and once in April or May." And he adds, "There seems no reason to doubt that the Glastonbury Thorn is a peculiar variety, which blossoms twice a-year, once being about Christmas time, but with a variation of a month or more according to the weather, as is the case with the Furze, the Mezereon, and the Hazel." But there still seems a difficulty in getting to the bottom of the history of this Hawthorn variety, for supposing a winter-flowering as is stated, it is more reasonable to expect the second flowering would not be earlier than the average, but rather later. Nor am I aware that the assertion made by some writer has been verified—namely, that seedlings of the Glastonbury Thorn exhibit the normal habit only, and to obtain winter-flowering specimens propagation must be by cuttings.—C.

### THE WEST OF ENGLAND ROSE SHOW.

NEMESIS, dire revenge, has overtaken the writer of this article, and many will be the chuckles and expressions of delight which will proceed from the mouths of "D., Deal," Mr. George Paul, and notably Mr. Lacharme when he sees these pages; for, astounding fact though it be, it is also true that my Baroness de Rothschild was beaten by Madame Lacharme at Hereford on July 13th, 1876! For five consecutive years had I taken the first prize with the Baroness in the class for twelve blooms of one variety, and I fondly hoped I should do it again; but the fates in the persons of two of the finest Judges in England, Mr. George Paul and Mr. Cant, decided that I should sing second to Madame Lacharme. This was the only drawback to a most successful Show—a Show, too, which was, I think, the finest ever seen at Hereford.

Four nurserymen were in magnificent bloom. Messrs. Cranston & Mayos, Messrs. Paul & Son, Mr. B. R. Cant, and Mr. Davison of Hereford, all put up superior stands. The schedule was a most liberal one, for in addition to the ordinary prizes for seventy-two varieties, was another open to the United Kingdom with the exception of the county of Hereford, and for this seventy-two no less a sum than £20 was given for the first prize, £10 for the second, and £5 for the third. These grand prizes, however, only produced three competitors, and one of these was not at all in form. Messrs. Paul & Son and Mr. Cant, however, staged remarkably well, and it was a great treat to go over their stands and notice each bloom carefully. I and Mr. Baker were the two Judges, and I do not think I ever enjoyed anything more than judging those stands with him. We had kindred minds and the same ideas as to the rules of judging. We took each bloom singly, and determined not only whether it was a grand bloom, but whether the variety was represented in proper form. We did not expect to see a Duke of Wellington the size of an Etienne Levet, or a Countess Nadailac as large as a Gloire de Dijon. And that I think and contend is the right way to judge, and the test of a good judge is to be able to know whether each Rose was in fair form, fresh colour, and in perfect condition.

Mr. Cant was first, and considering that one of his boxes miscarried and did not turn-up till too late to be of service to him, and also taking into account the length of the journey and the time (thirty hours) that his blooms had been cut, and not forgetting what tremendous heat they had to contend with, I think that no greater triumph has ever been achieved than his winning the first prize at Hereford for the open seventy-two. To mention his fine blooms would be like marking seventy-two of the finest sorts from one of his catalogues and writing "superb" against each. There was hardly any fail, I do not think three blooms could be found which the severest censor could find fault with. But some of the blooms I admired most were Mons. Noman, a variety always shown well by the Colchester grower; Mdle. Marie Finger, François Michelon, and Madame Lacharme among the lights; and Pierre Notting, Reynolds Hole, Charles Lefebvre, Marie Rady, and Auguste Newman among the darker varieties.

Mr. George Paul showed some excellent Teas, among which was one I had never seen good before—Mons. Furtado. He had the most perfect bloom of this in his close seventy-two stand, and one nearly as good in the open seventy-two. He also showed some marvellous blooms of old varieties which we rarely see good now, notably Queen Victoria, a Rose raised at Cheshunt; and La Duchesse de Morny, Thérèse Levet, and Madame Clert. In his seventy-two were grand proofs of the benefits he has conferred upon the Rose world in general, for he showed no less than six of his own seedlings—namely, Empress of India, Duke of Connaught, Reynolds Hole, Richard Marnock, Sultan of

Zanzibar, and The Shah, and these were all good Roses and which will be welcome additions to our gardens.

Messrs. Cranston & Mayos "swept the board." They took first in every class save one, and that one was (hear it and rejoice, Mr. William Paul) where their grand Rose Sir Garnet Wolseley was beaten by Star of Waltham. Of course, at Hereford we expect to see Mr. Cranston very fine, but considering the weather and the exposed situation of his nursery the stands he staged were simply wonderful. For months he has had no rain, and at King's Acre he has to pump every drop of water. This drought succeeded the coldest spring and the longest winter he has had for years. His soil is one that requires moisture more than any other, and he is more dependant upon a genial season than any of his great rivals, and yet he showed us blooms that would lead you to suppose that everything had been in his favour. It was hard to believe, as we walked over his nursery and saw how dreadfully he suffered from want of rain, how the Roses we had seen could have come from there; but at the very extremity of his nurseries we found an orchard which had been broken up two years ago, and there, under the shade of Apple and Pear trees, the plants had done well, and given him nearly all his blooms.

But, among other surprises I had this year at Hereford, I must notice the marked improvement made by Mr. Davison. He showed a stand of twenty-four blooms of Fisher Holmes which were simply perfection, and which caused the only difference of opinion between myself and my brother Judge. In this class we had seven stands exhibited—three of Marie Baumann, one of Horace Vernet, Maréchal Niel, and Alfred Colomb. The first prize was won by Mr. Cranston with Horace Vernet, and the second, after calling in an umpire, by Mr. Cant with Alfred Colomb. I was most anxious to give the second, or at least an equal second, to Fisher Holmes, but the general feeling was against me, although I rejoice to say Mr. Cant (the winner) assured me he thought I was right.

And now for the amateurs. Messrs. Cranston & Mayos most liberally offered a challenge cup value £15 15s., to be competed for by amateurs. This, of course, brought a great number of exhibitors. Mr. Arkwright of Hampton Court, Mr. T. Jowitt of Hereford, Mr. Baker of Exeter, Rev. Charles Evans of Solihull, and myself were the principal exhibitors. Mr. Baker and myself had to cut our blooms twenty-four hours before Mr. Jowitt and Mr. Arkwright; we had also a ten-hours journey on one of the hottest days of the year, and I had to change my boxes no less than four times, and yet we ran the Hereford men hard, or so we think. Mr. Jowitt won the cup, and won it well; and a first-class rosarian and a most enthusiastic exhibitor now enjoys the great happiness of excelling in his second year as exhibitor the giant Hercules, his powerful neighbour at Hampton Court, and all the rest of us. The Rev. Charles Evans was placed second, Mr. Baker was third, and they were kind enough to give me an extra.

There was very great competition in all the other stands, and the prizes were won principally by Mr. Arkwright, Mr. Baker, Rev. C. Evans, and myself.

And now let us say a word or two about the hospitality of Hereford, the graceful adjuncts of the lovely Show. It would require the pen of a nineteenth-century Horace to tell of this. Mr. Cranston entertained all the great nurserymen and the principal amateurs in a manner which I wish that many others would but imitate. It was a show and a meeting long to be remembered by others besides—J. B. M. CAMM.

## WEST OF SCOTLAND ROSARIANS' SOCIETY.

JULY 12TH AND 13TH.

WHILE the West of England has been holding its tournament in honour of the queen of flowers, at which I had been earnestly requested to be present, our friends over the border had been at the same time honouring her at the beautiful little town of Helensburgh, situated at the entrance of the Garelock—a situation which may well challenge any other watering place that I know, and where some most enthusiastic lovers of the Rose have started, and will I hope be able to maintain, a flourishing Exhibition.

The Show was undoubtedly held a little too early for the northern growers in such a season as this has been, and possibly even better blooms than those exhibited might have been brought forward had the Show been later; and as the north of Ireland is apparently somewhat earlier the finest blooms came from thence. There is one peculiarity connected with this Exhibition, and that is that the Society supplies all the stands, or rather supplies tables pierced with holes into which the tubes are placed, and are then covered with moss. Like many innovations it has its advantages and disadvantages. It places all the exhibitors on the same level. It does away with the difficulty that committees have of arranging the amount of room required from the unequal sizes of the boxes. Some persons will exhibit, say, forty-eight blooms in boxes which take up twice the room of another exhibitor. The disadvantages are

these: There is no bringing of two boxes together, as one often likes to do when they run very close, in order to compare them; then when people do not bring their entries, the spaces are vacant, and these have to be filled with spare blooms, which has a tendency to create confusion, and which ought not, I think, to be placed until after the Judges have given their decision.

I find that not only here but all through Scotland the vicious principle of showing Roses with added foliage has been adopted; but I trust that our friends there will see that this is what every true lover of the Rose would desire to see abolished. Independently of every other consideration, it ought to be remembered that sometimes a dishonest exhibitor will put up two blooms of the same Rose in his stand and give them different names. It may be oftentimes very hard to distinguish them, and if there is foliage added it is almost hopeless, but where they are shown as cut from the Rose tree the wood will often lead to an identification; and as to the statement that they cannot get such foliage as in the south, I can only say that in the evening I took a santer through Messrs. Robertson & Galloway's grounds, and found as robust foliage as I should wish to see anywhere.

It would hardly interest the readers of the Journal were I to particularise the different stands and give the names of the blooms. In truth there is very little difference. Wherever a show is held the same blooms are to be seen. What stand is complete without Charles Lefebvre, Marie Baumann, La France, Madame Victor Verdier, and other Roses which we all know by heart? I may say, however, that in the Messrs. Dickson's of Newtonards, Co. Down, Ireland, was one of the finest blooms of Mdlle. Marie Cointet that I have seen, and which gained the prize as the best Rose in the nurserymen's class, and a seedling of their own called Alex. Dickson, a large, full, and peculiar-looking flower in the way of Madame Schmidt, and Mons. E. Y. Teas, evidently one of the best Roses of last year; and shall I not add—(aye, Mr. Camm!)—Madame Lacharme, which has this season been neither "as coarse as a navy or as dirty as a scullion?" The gardeners of Major Dumistorn and Mr. Watson, the President of the Society, exhibited some remarkably fine blooms. I have never seen Baronne Maynard exhibited so well; and the best bloom of La France that I have seen this year was in the former gentleman's stand, while the latter obtained the premier prize in his class for a grand bloom of Etienne Levet.

As in most of these cases of a successful show there is one leading spirit to whom the results are in a great measure due, so here it is to the indefatigable exertions of Mr. Galloway of the firm of Robertson & Galloway that the present position of the West of Scotland Rosarians' Society is to be attributed. His is not a provincial name merely. Many of our London friends will recollect how last September he came up with a magnificent stand of Gladioli and wrested the championship from that veteran and successful grower Mr. Kelway. He has worked with a will, and has been ably seconded by the Directors of the Society. I know of no young Society which has a better promise of lengthened days, and I shall ever esteem it a happy thing that I was enabled to go so far north to assist in their tournament in honour of the queen of flowers.—D., Deal.

## NEW BOOK.

*Complete Manual of Orchid Culture.* By EDWARD SPRAGUE RAND, JUN. Hard & Houghton, New York.

LIKE the "Orchid Manual" by Mr. B. S. Williams, this book has been prepared by an enthusiast in Orchid culture. The author's experience has been gained at Glen Ridge, near Boston, and the cultural directions are more intended for American than English gardeners. The following advice on purchasing Orchids should be noted by those intending to commence their culture. "If a dealer wishes to disgust a beginner with Orchid culture, let him send him a dozen plants for twenty-five dollars. Put the same money into two or three good plants, and the result will be a virulent attack of Orchid fever." "Orchids," continues our author, "are the élite of the floral kingdom; they combine more of beauty, fragrance, and singularity of structure than any other family of plants, and, certain rules being observed, are generally as easily grown as Roses, Pinks, and Violets." We agree with the first part of this paragraph, but not the last. Orchids are not as easily grown as Roses and Violets, nor can they be grown by the observance of certain rules. A grower may observe certain rules at one place, and be quite successful in the culture of certain species. He may observe the same rules at another place and in a similarly constructed house, and just be as unsuccessful as he was formerly successful. Take one or two species as illustration. A gardener grows a batch of *Phalenopsis* remarkably well, the leaves and flowers even surpassing those of their native wilds. In two or three years these fine plants will begin to die-off or go back, until they are a wreck of what they used to be; and all the care and anxiety

of the same cultivator cannot help it. Splendid plants of Goodyera will go back in the same way after being grown up to a high standard, and drag out a miserable existence for a few years. This does not happen to Roses and Pinks, and the observance of certain rules will not prevent it.

The chapter on Orchid culture in the United States is interesting, as showing the increasing attention paid by cultivators in America to this fine class of plants. There is a long descriptive list, which occupies 272 pages. Part of it is the author's own, but he has also made free use of the "Orchid Manual" and other works, which he likewise freely acknowledges. His popular descriptive list might be greatly increased in value if cultural directions had been given with those species of any genus requiring special treatment. Take for instance *Cattleya superba*. It is one of the most beautiful of the whole genus, and all we are told about it is "that it is a slow-growing species, that requires more heat than the other *Cattleyas*," and "it should never suffer for want of water." Not a word is said about any special treatment; but pot it, and treat exactly like *C. Mossii*, *C. Warnerii*, *C. crispa*, &c., and the plants would all be dead in six months. Fasten it to a block like some other *Cattleyas*, and it will not succeed for any length of time. The best way to grow it is on the stem of a Tree Fern. On this the plants will grow and flower freely for many years. It requires the heat of an East India house. Information of this sort is not only valuable for beginners, but those who have grown Orchids for many years are sometimes at a loss to find out the right treatment for a special plant. Still this descriptive list contains a mass of very useful information, and the book as a work of reference will be very useful.

## PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

*COSMIBUENA OBTUSIFOLIA* var. *LATIFOLIA*. *Nat. ord.*, Rubiaceæ. *Linn.*, Pentandria Monogynia.—"This handsome plant seems to be widely spread in the hot valleys of the Andes of Cauca in New Grenada to Tarapoto in Peru, forming a beautiful small tree 20 to 30 feet high, with white fragrant flowers and a slightly bitter bark. *C. obtusifolia* was sent to Kew by M. Linden of Brussels under the name of *Cascarilla grandifolia*, which I do not find in any publication; it grew to a considerable size in the Palm house, but never flowered. A cutting, however, given to Mr. Howard and placed in a stove speedily flowered, and from it the accompanying drawing was made. The Peruvians, according to Mr. Spruce, call this plant 'Azahar-sisa,' because the flowers smell like 'Agua de Azahar' (orange-water).—(*Bot. Mag.*, t. 6239.)

*PESCATORIA LAMELLOSA*. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Flowers yellow, orange, and brown.—"P. lamellosa is not nearly so handsome a species as P. Dayana, though sufficiently attractive. It flowered at Veitch's establishment in August of last year, to which the plants were sent by its discoverer Mr. Wallis from New Grenada."—(*Ibid.*, t. 6240.)

*CORROPSIS* (*TUCKERMANNIA*) *MARITIMA*. *Nat. ord.*, Compositæ. *Linn.*, Syngenesia Frustranea. Flowers yellow.—"A native of maritime rocks in California, where it was discovered by Nuttall in 1834-5, and introduced by him into American gardens, and from whom we have dried specimens collected at St. Barbara and at Utah. There are also specimens in the Hookerian Herbarium, collected earlier still by Coulter, but from what precise locality is not indicated. The specimens here figured were received from Mr. Thompson of Ipswich, and flowered both at Kew and at Ipswich in September, 1873-4. It is described as a perennial in America, but is of annual duration in this country."—(*Ibid.*, t. 6241.)

*TULIPA HAGERI*. *Nat. ord.*, Liliacæ. *Linn.*, Hexandria Monogynia. Flowers scarlet, yellow, and green.—"It was discovered by Dr. Von Heldreich in 1862 on the hills of the Parnes range in Attica, growing with *T. Orphanidea* at an elevation of 1600 feet above sea level. The drawing was made from a specimen presented by Mr. Elwes to the Kew collection, which was in full flower on the 24th of April of the present year, and we have also received it from the Rev. H. N. Ellacombe and Rev. H. Harpur-Crewe."—(*Ibid.*, t. 6242.)

*MORICANDIA SONCHIFOLIA*. *Nat. ord.*, Cruciferae. *Linn.*, Tetradynamia.—"This very showy Crucifer, though described as long ago as 1832, has hitherto been known only from dried specimens collected by its discoverer, the veteran traveller and botanist, Professor Bunge of Dorpat, who accompanied a Russian mission to Pekin from Siberia in 1831. It is a hardy annual, remarkable for the bright colour and delicacy of its

purple corolla, and being easy of cultivation is likely to become as great an acquisition as its near ally, the old garden favourite, the European *M. arvensis*, which has been in cultivation since 1739. Another species is the beautiful *M. Bamburii*, a native of Spain. The Royal Gardens are indebted to Dr. Playfair, late medical officer attached to the Embassy at Pekin, for seeds of this plant, which flowered in March of the present year."—(*Ibid.*, t. 6243.)

**APPLE—Worcester Pearmain.**—"None of the Apples to be found in our gardens and orchards excel the Worcester Pearmain in brilliancy of colour. The symmetrical form and good quality of the fruit, combined with its charming and attractive colour, must give it one of the most prominent places among dessert Apples; while from its free growth and great productiveness, it cannot fail to claim the attention of all who grow fruit for profit. It bears as freely as the well-known Apple Lord Suffield, and must soon become one of the leading sorts for market, as well as for exhibition; indeed, no collection should be without it. We have to thank Mr. R. Smith of Worcester, who holds the stock of this Apple, for the specimens figured, and which are very faithfully portrayed by Mr. Macfarlane. It is a beautiful Apple, as the illustration shows, and that it is as good as it looks is the general verdict which has been given wherever exhibited. It was much admired by the Fruit Committee of the Royal Horticultural Society when shown at South Kensington on October 6th, 1875, and was awarded a first-class certificate. The tree is said to be a seedling from the Devonshire Quarrenden. The fruit is medium-sized, 2½ inches wide and the same in height, conical, very symmetrical, and pearmain-shaped, with a smooth glossy skin, which is completely covered with a brilliant crimson-red, dotted with minute fawn-coloured spots. The eye is small and prominent, surrounded by a few plaits. The stalk is three-quarters of an inch long, deeply inserted in a russet cavity. The flesh is white, tender, crisp, sweet, and very pleasantly flavoured. It ripens in August and September, and will keep until Christmas. This exceedingly handsome Apple is sure to become a general favourite."—(*Flor. and Pom.*, 3 s. ix., 121.)

## GLASS HOUSES VERSUS BRICK WALLS FOR FRUIT CULTURE.

PERHAPS there is not another country in the world where there is such an amount of money invested in, and so much skill and persevering energy applied to fruit culture, with such a small return in the way of fruit crops of a certain class, as in Great Britain. If, for example, it be considered how much money it takes to erect good garden walls, and the labour expended in the making of suitable wall-fruit borders, the concreting, the draining, and the bringing-in of good soil in the majority of localities—for these preliminaries the outlay is immense. Then there is the purchase of expensively trained trees; the annual and constant care required in pruning, pinching, and training, besides the almost continuous battle with a numerous train of destructive insects of one sort and another, and the abortive expedients put in operation annually with the object of saving the blossom from frost and blasting east winds. The sum total of capital invested and labour annually expended is, we might almost say, appalling in comparison with the return in crops of good fruit in the case of such as Peaches, Apricots, Plums, Pears, &c. This, it must be admitted, is of wide application. The wonder is that this losing game has been so long and perseveringly persisted in. We are confident that, in the case of any other department, so fruitless an expenditure would soon be abandoned in despair. No doubt the necessity for walls as a fence and for shelter accounts for this state of things to a great extent.

In a great many localities a good crop of fruit about once in five years is about as much as can be counted on; and perhaps, taking one year with another, the returns in some localities would not pay for the shreds and nails necessary for training the trees. This rule does not, of course, apply to those parts of the kingdom that are more favoured in the way of climate and soil; and in their case walls do good service in producing fine dessert Pears and stone fruits. It is not to these districts that we wish these remarks to apply. Yet, even the most favoured spots in England are not always free from such weather as destroys even wall-fruit crops. But in such unfortunate districts as those to which we are directing our remarks, an amount of disheartening mishaps to wall fruits has to be faced annually, which, it is not too much to say, would

serve to put an end to any other pursuit; while, at some altitudes the work is stoically carried out without any hope whatever of gaining the end in view.

In the times, happily now gone by, when glass was dear and there was no steam-driven machinery for woodwork, there was less cause to wonder at the persistency with which ugly walls were built and hid out of sight of the mansion as an eyesore, and more as a necessary evil for the purpose of a fence and shelter to tender crops than anything else. What can be uglier in a park landscape, especially if it can be looked down on, than a square piece of land hemmed-in with hideous red brick walls? It is as complete a blot on any landscape as can be well imagined; and in the making of new gardens now there is but little excuse for the erection of walls in localities where the climate is not such as to make them give a fair return in fruit crops. Now that machinery driven by steam has taken the place of the ordinary saw, plane, and mortising chisel in the construction of the woodwork of glass houses, and glass is less than half the price it was at one time, a brick wall should never be thought of in many localities for the growth of certain fruits. The difference between the construction of a 15 or 18-inch brick wall and the erection of span-roofed glass structures is not very great; and we are certain that we are within the mark when we say that the bearing surface protected with glass would, taking the average run of seasons, yield quite three times as much and finer fruit than the same surface of walls. If this be so, then it is beyond a doubt that the same money expended on glass as is necessary for walls would yield a larger and better return in fruit; while for the mere purposes of shelter, that can be obtained in a much more ornamental way than by building ugly and unproductive brick fences.

Of course, in the case of old places where the garden walls already exist, it is easy to cover a portion of them with glass, and on a comparatively small area secure three times the fruit that the whole wall surfaces produce of certain fruits. This is a class of structure now getting to be more appreciated. They are adopted in many instances; and we never heard of an instance where they have been brought into operation where the doing so has been regretted, but the reverse. And they cannot be too strongly recommended, not only for the certain return of fruit crop, but for the pleasure they yield into the bargain. No doubt some may be prevented from adopting glass instead of bricks and mortar, from the impression that glass houses are very expensive in tear and wear. It should, however, be remembered that glass houses kept cool and airy and comparatively dry require very little paint compared to ordinary plant and forcing houses; and also that houses as now erected, with a minimum of wood and a maximum of glass, require not half so much paint as the old style of houses. As a matter of pounds, shillings, and pence, even glass houses will pay better than brick walls in very many localities when devoted to the culture of the fruits named at the commencement of these remarks. Besides, such erections can be profitably made use of for other purposes besides fruit culture.

Perhaps some may be inclined to say that we are now merely advocating the orchard-house system—one which is common enough. It is not quite our aim to do this. What we wish to recommend to those who may have new gardens to make in bad climates is, instead of going in so heavily for mere brick and mortar, to invest their money in glass, with the absolute certainty of obtaining regular crops of good fruit instead of running a hundred risks on the bare wall system. Then, as to the furnishing of such erections, some may ask, Are we to cultivate in pots or in borders in the usual way? To the amateur or small grower who would like a variety of fruits from a small glass house, pots do very well; but where fruits are wanted of the very best quality, in great quantity, and with least possible labour, we say Plant your trees in well-prepared borders. Mr. Rivers, the populariser and most successful cultivator of fruits in pots under glass, has set this point at rest most clearly, and so have others as well. In the *Journal of Horticulture* some years ago he balanced carefully—to his credit be it told—the pot system of growing bushes of Peaches and other fruit commonly grown on walls and that of trees planted out and trained to trellises, and showed that a fourth more could be produced by the latter system than by the former.

Moreover, the expense of furnishing a house with trees in pots is much greater than that of furnishing it with trellis-trained trees. The after-labour is also much more, and the chances of failure are also increased by having recourse to trees in pots. As has already been remarked, the system is only to

be recommended when a great variety of fruits in small quantity is the object from a small house. And if expense is not an object, pot trees may be had recourse to in the body of any glass house or case till the permanent trees come into bearing and cover the roof. Stone fruits of all sorts and some varieties of Pears do very well in pots; and such Apples as Calville Blanche are worthy of a place in such structures, both as permanent trees and in pots for a while at first.—(*The Gardener.*)

## NOTES ON VILLA AND SUBURBAN GARDENING.

**KITCHEN GARDEN.**—The weather having set in so dry with intense heat many crops must have special attention to carry them to perfection. For instance, Scarlet Runner Beans will need a heavy mulching for some distance on each side of the rows, and by first stirring the soil and then afterwards giving a thorough soaking, the water will wash some of the nourishing properties out of the manure and carry it into the soil, much to the benefit of the crop. Dwarf Kidney Beans, too, must be similarly treated, or the blooms will not set their pods.

Peas that have been sown in trenches are standing the drought much better than others sown on the level, though they are all stopped in their growth more or less. James's Prolific Marrow is a splendid Pea and delicious in flavour. With me it is better than G. F. Wilson so far as cropping goes, but about the same time in coming in; they are both Peas of the highest merit. Mr. C. Turner's Dr. Maclean is a marvellous Pea; the growth is very vigorous and the pods large; the peas are also large, and from eight to ten in a pod. These dwarf Marrow Peas, such as the above, are to be recommended in preference to the tall Peas for villa gardens. They may not crop so successively as the tall Marrows, but by sowing a little oftener it is easy to keep up the succession. Most of these dwarf Peas make their growth first, and when the crop is fit for use they cease growing, while the others grow and produce pods at the same time. This is the only advantage of tall-growing Peas.

Let newly planted Celery be shaded for a time and be well watered in the evenings. There are many complaints about the maggot in the leaf; this must be picked off immediately it is seen, and be either smashed or burnt. In such weather as we are having is the time when its ravages are most severe.

Break up a piece of ground and make it rich, and put out a bed of Parsley from the seed sown in spring. This is the only way to produce a supply for winter. Plants thus grown produce large leaves, whereas plants left in the seed bed dwindle away towards winter and often fail when Parsley is in particular request.

Let all Broccolis, Savoy, and Coleworts lately put out be well supplied with water, and if possible let the soil be well hoed. It is most difficult in such trying weather to get Endive, Lettuce, and all small crops established; but if the ground is well worked and the plants are watered-in they will partly establish themselves, so as to grow freely when showery weather comes.

If Tomatoes have been attended to they will be coming into flower now, and must be regularly stopped above each bunch of bloom and the shoots well thinned out. No neglect must be permitted in watering and mulching to keep them growing during the short time there is for them to do their work.

Everyone must keep a watchful eye over the Potato crop. About here the early sorts are ripening and will soon require to be taken up. The tubers are very small. The coarse-growing sorts will be the best this year, but even many of them are showing signs of ripening; and if rain should come before long it may save them, but if not the tubers so far ripen off as to begin growing again immediately enough rain comes to reach them they will be spoiled. When it comes to such a crisis as that I would advise the crop being taken up immediately.

Cauliflowers are feeling the effects of the drought and turn in small. Veitch's Autumn Giant is the only sort that endures the heat well: even these will not produce very large heads if dry weather continues. Prepare a piece of ground and enrich it, and as soon as showers come and a dull day or two put out a good breadth of plants for autumn use, when they will keep up a supply along with the White Cape Broccoli.

It will be as well to sow a good piece of ground with Dwarf Kidney Beans; they often do better than the earliest crops, and are always in request. Outdoor Cucumbers are doing better than usual; by this time last year several of my plants had died off.

Turnips for an autumn crop must be considered. It is very little use sowing while the weather is so hot, but the ground may be had in readiness, and immediately rain comes the seed may be sown, and it being seed which very soon germinates, no time would be lost by waiting for rain. Two or three ounces of seed will produce sufficient Turnips for the supply of an ordinary family.

Onions that are bulbing fast and with their tops vigorous ought to be laid down in a gentle manner. Some people do not hold with that plan, but would prefer "blading" them, or in

other words taking off several of the coarsest leaves in order to throw strength into the bulb similar to that practised with Leeks.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

We have now cleared off the early Cauliflowers and early Peas, and have begun to prepare the ground for Strawberries. The runners will be ready for planting out in a week or ten days, but we shall not put them in the ground in that time unless it should rain. The old plants were attacked with mildew almost as soon as the runners were laid into the pots. This year, as well as other seasons, the variety most liable to injury from this parasite is *Amateur* (Bradley); it could not be fruited in pots on that account, and it will be discarded altogether after this season. When one variety is attacked all the others in the immediate neighbourhood are likely to suffer. *Black Prince* was the next that has been seriously injured; but this sort so seldom suffers from mildew that we shall not make any difference either in the number saved for potting or planting out. *Keens' Seedling*, *President*, *La Constante*, *British Queen*, *Mr. Radclyffe*, *Frogmore Late Pine*, *Duc de Magenta*, *Auguste Nicaise*, and some of our own seedlings have suffered but little from it. As some correspondents have been writing about Sir J. Paxton, it may be as well to say that our experience with it was similar to that of "W." and "J. J.," it was discarded after two or three years' trial. On some soils it is one of the finest Strawberries.

Planting of green crops, such as Coleworts, Savoys, Sprouting Broccoli, &c., has been delayed for want of rain. The ground is thoroughly dry and the heat excessive. On Thursday last the maximum temperature in the shade was 90°, on Friday 91.5°, with an east wind and very dry atmosphere. The ground will be prepared for the crops and the plants will be put out on the first favourable opportunity.

Leeks are seldom planted in this neighbourhood, but in Scotland they are grown everywhere, and are much esteemed in the kitchen. Cottage gardeners take a pride in growing fine Leeks, and often eclipse the professional gardeners at the autumn exhibitions with them. Leeks are very gross feeders, they delight in rich semi-decomposed pig manure, and this the cottager can sometimes supply when the professional gardener cannot. The Leeks are planted in trenches, or rather deep drills, about 15 inches apart and 9 inches between the plants.

Lettuce, Radish, and other small salads must not only be sown in a shady position, but they must be also well watered. Endives should be sown at once if the ground should be moistened with rain. It is splendid weather for harvesting crops. The autumn-sown Onions are a fine crop, they are nearly ready for lifting; as soon as they are quite ripe they will be pulled up and laid on the ground to dry. The weeds do not grow much, but where they are growing they should be hoed up and removed to prevent the seeds from growing again. Weeds seed more readily now than at any other season of the year.

### PINES.

The very hot weather is ripening the Queens very rapidly. We shall be glad to have them all out, as the suckers are very strong and ought to be potted at once. It is seldom possible in ordinary establishments to pot strong suckers early in June, repot them again the same season, and have fruit ripe from those plants in June and July the following season; given strong suckers a good house well heated with plenty of room for the plants, and it can be done as easily as growing *Scarlet Geraniums*, but where a succession of fruit is kept up all the houses are full and there is no room for the suckers. Our own are grown in a very small lean-to house which is not adequate to their full development; but they cannot even be put into that house until the succession plants are moved into the fruiting house, and even though the first fruits are ripe, say in June, the latest cannot usually be cut until July or even the first week in August.

Succession plants are in their fruiting pots, and these are quite filled with roots when they are removed to the fruiting house. But little bottom heat will be necessary, and plenty of air must be given to them. They require a good deal of water at this season, and it is necessary to look over the plants twice a week. They have nearly all been potted in 11-inch pots. The tan in the bed has sunk considerably, but it is not safe to add much fresh to it at this season, as the bottom heat will rise from this cause alone to 120°. Newly-potted plants might be plunged to half the depth of the pots in this without injury, but where the roots are matted round the sides and the bottom of the pots such a heat would kill them and ruin the plants. If it was thought better to turn the tan and mix it with fresh and the heat became violent, the pots might be placed on the surface until the temperature of the bed fell to 85° or 90°, when the pots might be plunged.

### PEACH HOUSES.

Our trees in pots take large quantities of water at this season,

and a few hours' neglect may ruin the crops of fruit. When the trees are planted out in a border where the roots can run where they like, there is no danger of the trees being injured by drought if ordinary precautions are used. When the trees are watered it must not be applied in dribbles, but a thorough soaking should be given so that the water may reach the bottom of the border. Before applying the water some rich manure should be spread over the surface, the nutritive properties of which are washed down with the waterings. This is preferred to mixing the water with manure and applying it in that way.

Instructions have been repeatedly given to thin-out all young wood not required for fruiting next year, and to ensure the proper ripening of the present crop the trees must be thoroughly syringed night and morning up to the time the first fruits become soft when taken in the hand. At this time there should be no trace of red spider or thrips, because syringing must be withheld and the pests would be left in undisturbed enjoyment of a rich pasture ground for the next six weeks.

Early houses from which all the fruit has been gathered should have the top lights, if convenient, removed, or at least all the ventilators ought to be opened to their greatest extent night and day, and the trees ought to be quite free from all insect pests. Thrips and the Peach aphid may be destroyed by fumigating; but red spider will only yield to thoroughly washing the leaves with the garden engine.

### GREENHOUSE AND CONSERVATORY.

The season is now drawing near when the Dutch bulbs must be ordered for next season. Some of the more energetic members of the trade are already sending in their lists, and it is certainly good policy to send in the orders in good time. Hyacinths are the most favourite bulbs, and almost everybody, whether they have a garden or not, contrive to grow some. It is not worth while here to give a list of the best sorts, nor under ordinary circumstances is it best to order the bulbs by name. Any respectable dealers if they received an order for so many dozens at so much, would be better able to select than the buyer would, and at a less rate. The word respectable dealers is used advisedly, as there are some who advertise roots which they recommend at a price for which the best roots cannot be obtained in Holland. Having exhibited Hyacinths successfully for many years, some of the Dutch growers send their lists here, and some of the sorts are certainly cheap enough, but they are sorts that will not do for us, and the trade know them; but comparing the prices of the best sorts that are grown in England with the English lists, there is but little difference. The soil ought to be prepared by this time, and laid up in a heap until it is time to pot the bulbs. Good turfy loam, leaf mould, and cow manure in nearly equal proportions is a good compost, to this must be added a little silver sand. Tulips are next to the Hyacinth in popularity, and they have a fine effect when arranged with the other plants. We grow the Hyacinths one in a 6-inch, and the Tulips three in the same sized pot. Stable manure is used instead of cow manure. Polyanthus Narcissus are very much admired by some, and they are potted and treated similar to the Tulips.

All the stage Pelargoniums have been turned out of doors. Very little water is given to the plants, and in a few days when the wood is sufficiently ripe the plants will be cut down. When it is desirable to obtain a succession of bloom the plants must be cut at different times, the bloom will then last from May to the middle of July, but we always have the best bloom about the middle of June. If it is intended to put in any cuttings this ought to be done when the plants are cut down. They ought to be potted in light sandy soil in small pots. If it is intended to propagate a quantity a dozen cuttings may be planted in a 5-inch pot, but when there are only a few choice sorts it is better to place one cutting in the centre of a small pot; the pots should then be placed on the stage of the greenhouse, and water ought not to be applied too liberally. Zonal Pelargoniums of all the sections make a very fine display, and continue much longer in beauty than the stage or fancy sorts.—J. DOUGLAS.

## TRADE CATALOGUE RECEIVED.

Little & Ballantyne, Carlisle.—*Catalogue of Bulbs, &c.*

## HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

THORNTON HEATH. July 21st and 22nd, and September 1st and 2nd. Mr. W. Baines, 10, St. John's Villas, Bensham Manor Road, Thornton Heath, Hon. Sec.

TWEKESBURY. July 25th. Mr. P. Moore and Mr. H. J. Cochrane, Hon. Secs.

WREXHAM. July 25th. Mr. J. B. Shirley, Hon. Sec.

HUNTINGDON. July 26th. Mr. J. Dille, Market Place, Sec.

HEADINGLEY. July 26th and 27th. Mr. T. Atkinson, Barleywood, Headingley, Leeds, Sec.

ABERDEEN (Royal Horticultural Society). July 26th, 27th, and 28th. Mr. Archibald J. Kennie, 123, Union Street.

BRIGHTON. July 29th. Messrs. C. Jessop & E. Rawnsley, Hon. Secs.

**SALTAIRE.** July 29th. Mr. G. A. White, Hon. Sec.  
**KILSEY (Flowers).** August 1st. Mr. C. E. Bracebridge, Sec.  
**HEWORTH (Horticultural).** August 2nd. Mr. B. H. Felton, Hon. Sec.  
**RAWNSTALL (ROSENDALE).** August 4th and 5th. Mr. M. J. Lonsdale, Sec.  
**SOUTHAMPTON.** August 5th and 7th. Mr. C. S. Fudge, 89, York Street, Sec.  
**FINEDON.** August 7th. Mr. G. C. Mann, Sec.  
**TAUNTON DEANE.** August 10th. Mr. F. H. Woodforde, M.D., and Mr. Clement Smith, Hon. Secs.  
**FLEY.** August 11th. Mr. Walter Fisher, Hon. Sec.  
**OTLEY.** August 12th. Mr. Alfred Suttle, Hon. Sec.  
**CLAY CROSS.** August 15th. Mr. J. Stallard, Clay Cross, near Chesterfield, Sec.  
**WESTON-SUPER-MARE.** August 15th and 16th. Mr. W. B. Frampton, Sec.  
**PRESTON.** August 16th and 17th. Mr. W. Troughton, Hon. Sec.  
**SHERWSBURY.** August 16th and 17th. Admitt & Naunton, Hon. Secs.  
**LEDBURY.** August 17th. Mr. J. B. Masefield, Hon. Sec.  
**NORTON, NEAR STOCKTON-ON-TEES.** August 18th. Mr. C. Turner, Sec.  
**MIRFIELD.** August 19th. Mr. G. Senior and Mr. J. Rushforth, Hon. Secs.  
**CALNE (Wilts).** August 22nd. Mr. H. Blackford, Sec.  
**NEWBURY.** August 22nd. Mr. H. Seymour, Hon. Sec.  
**DORSET COUNTY.** August 23rd (at Dorchester). Mr. A. Pope and Mr. C. Parsons, Secs.  
**CHEPSTOW.** August 23rd. Mr. B. Thorn, Hon. Sec.  
**CARSHALTON, WALLINGTON, AND BEDDINGTON.** August 24th. Mr. J. Baines, Leicester House, Carshalton, and Mr. W. Clark, the Nurseries, Wallington, Hon. Secs.  
**LARGO AND FAIRLE.** August 25th. Mr. D. G. Glen, Hon. Sec.  
**SEATON BURN.** August 26th. Mr. B. Richardson and Mr. W. Elliott, Secs.  
**ISLE OF THANET (MARGATE).** August 30th. Mr. C. D. Smith, 8, Marine Terrace, Margate, Sec.  
**POCKLINGTON.** August 31st. Sec., Mr. J. E. Ross.  
**MONTROSE.** September 1st and 2nd. Mr. Alex. Burnett, 2, High Street, Sec.  
**DUNDEE (International).** September 7th, 8th, and 9th. Mr. W. R. McKelvie, 26, Euclid Crescent, Sec.  
**GLASGOW.** September 12th and 13th. Mr. F. Gilb. Doughall, 167, Canning Street, Sec.  
**ROYAL CALEDONIAN HORTICULTURAL SOCIETY.** September 13th.  
**KILMARNOCK.** September 14th. Mr. M. Smith, 11, King Street, Sec.  
**IPSWICH.** September 17th. Sec., Mr. W. B. Jeffries, Henley Road, Ipswich.  
**ROYAL HORTICULTURAL SOCIETY, SOUTH KENSINGTON.** November 8th.  
**NORTHAMPTON (Chrysanthemums).** November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

**BURNING CLAY (Y. S. W.).**—As it is dry and friable, damp it so that the small lumps will cling together; it may be then banked over the fuel. When burned it will render a clayey soil more open to which it is applied.

**NERTERA DEPRESSA (A Lady in Cheshire).**—Directions for its culture are in our last number. You coddle it too much.

**STRAWBERRIES (W. L.).**—All of about average merit. The box may be useful for some purposes, and certainly for conveying fruit. The Strawberries were in perfect condition wrapped in paper and the box filled up with bran.

**PLUMS FOR WALL WITH WEST ASPECT (Connaught Subscriber).**—As you have plenty of Orleans and Victoria we advise you to plant Rivers's Early Prolific, Green Gage, Jefferson, Kirke's, Prince Englebert, Coe's Golden Drop, and Transparent Gage.

**PLUMS DECAYING (S.).**—The ulceration of the Kirke's Plum is caused by a defective supply of sap. More water to the roots and mulching the surface would prevent the decay.

**SEEDLING GERANIUM (J. R. W.).**—The trusses are large, and the colour a peculiar pink. As you say it is of sturdy habit, it will be useful for bedding.

**GOLDEN CHAMPION GRAPE CRACKING (G. R.).**—This is not an uncommon occurrence with this sort. The best treatment is to keep the Vine moderately dry at the roots when the fruit is swelling. Plenty of air ought to be admitted, and the atmosphere of the house should also be rather dry.

**ROSE LEAVES MOTILED (P. B. C.).**—We believe that the fault lies in the roots; sour undrained soil would cause it, or it might be from insufficient nourishment. If you lift the Rose in the autumn and replant in rich soil it will be all right. The spotting might be caused by mildew, but there is not any trace of the pest now.

**GRAPES DISEASED (W. A. B.).**—Two of the berries are attacked by what gardeners call "the spot." It is an ulceration caused by a deficient supply of sap. Watering the roots with very weak tepid manure water will prevent it. The other berry is rusted, and the brown roughness is believed to be caused by exposure to a draught of cold air.

**VINE LEAVES BROWNED (F. F.).**—The roots need watering abundantly and regularly during this hot dry weather.

**VINES OVER-LUXURIANT (Somerset).**—The leaf sent is very fine, and had your Vines sufficient space to grow in they would produce excellent Grapes. The roots have passed through the boundary wall, and have penetrated the subsoil. We should not hesitate to cut a trench by the side of the wall, severing many of the roots, and at the same time we should remove the surface soil from the border, just baring but not injuring the roots, and replacing with the charred soil you speak of, and surfacing it with a layer of stable manure. This may be done when the foliage turns yellow in the

autumn. What you want are surface—not subsoil—roots, then will your Vines be short-jointed and fruitful. Another plan which would produce Grapes would be to encourage the best Vine to grow and eventually occupy the entire house, removing the others by degrees as the permanent Vine makes fresh canes.

**GRAPES NOT COLOURING (J. P. Bath).**—Overcropping is the prime source of deficient colouring. The heavier is the crop and the drier the season the more support must be given to the roots. See an article in another column. Even now a soaking of tepid manure water may be of benefit to the crop.

**POTATOES MATURING (Lindum).**—As you say the "skins are set" we should certainly take up the early crop, storing the tubers thinly in a cool place. If left in the ground and heavy rains succeed the probability is that they would grow again—spertuburate, and the produce would be deteriorated in value. Take up the crop at once.

**INCREASING SEMPERVIVUM TABULEFORME (Tulse Hill).**—Plants are readily raised from seed, which should be sown thinly in gentle heat in the spring, or at the present time in a cold frame. The pots should be plunged, and shaded so that the surface of the soil can be kept regularly moist without frequently watering it; the seedlings to be potted in small pots when they are large enough to handle, and be grown in a frame or greenhouse. Plants may also be raised from leaves, slipping them off carefully and laying them round a pot of very light sandy soil, very slightly pressing the base of each leaf into the sand. These, if kept gently moist, will form incipient buds, eventually becoming plants.

**NEGRO LARGO FIG (A Nobleman's Gardener).**—This is a very fine Fig, and is well adapted for cultivation in pots. The fruit is large, nearly 4 inches long, black in colour, juicy, and refreshing. Mr. Fleming of Cliveden, who is known to be an excellent cultivator, considers this the best of all Figs for growing in pots. You may safely include it in your collection.

**YORK AND LANCASTER ROSE (Volunteer).**—This distinct old Rose will succeed well when budded on the Briar, but we should advise the tongueing or notching of the shoots of your dwarf plant, and pegging them in the ground in the autumn, when you would soon increase your stock of it. It is an acquisition for mixed borders and for shrubberies, growing and flowering freely in almost any kind of soil.

**PLANTS FOR BOCKERY (Nemo and others).**—We will reply in our next number.

**ORANGE FUNGUS ON ROSES (W. A. W.).**—No one can tell where the spores come from which give birth to this fungus. It is most effectually removed by sponging the leaves with a solution of 2 ozs. of blue vitriol (sulphate of copper) in two gallons of water. Dissolve the vitriol in a little boiling water, and then mix it with the cold.

**INSECTS ON APPLE TREES (M. J. T.).**—If by "lice" you mean the green fly, as the trees are small you may syringe them with tobacco water. Not knowing any of the circumstances we cannot suggest the probable cause.

**INSECTS IN PELARGONIUM SOIL (J. H.).**—We could not detect one in the sample. As they are small and white they are probably the common *Acarus*, and are harmless, living on decayed vegetable substances.

**NAMES OF PLANTS (S. C. A.).**—*Alstromeria pulchella*. (R. L. D.).—1, *Thalictrum flavum*; 2, *Campanula latifolia*. (W. T.).—1, *Veronica Teucrium* var.; 2, *Nepeta Musini*; 3, *Philadelphus coronarius*; 4, *Erysimum* sp. (F. L.).—*Polypodium Billardieri*. (W. P.).—We cannot name florists' varieties of flowers, nor Strawberry varieties, they are far too numerous and too nearly resembling others. (Penalty).—*Lycopodium helveticum*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### RAILWAY JOURNEYS.

THERE can be no possible doubt that poultry exhibitions could only have been very local without the aid of train service, and it is as equally certain that poultry shows must have from time to time very greatly added to the revenues of railway companies in their parcels traffic. Nevertheless, the charges for conveying a basket from one place to another would seem rather to increase than lessen, while the carelessness often displayed in forwarding baskets and knocking them about at stations is well known to all. There are some of the companies in the south of England which will return baskets free from a show on their own line of railway provided they remain the property of the exhibitor; among them the principal are the London, Brighton, and South Coast, the London and South-Western, and the South Devon, Cornwall, and West Cornwall Railways. Now we cannot be sufficiently grateful to these companies, and always feel inclined to make use of these lines of rail when possible, even if we send our birds a little out of the way to do so. We have exhibited in every county in England, and consequently have had to pay the charges of all lines, but we find no one of them so expensive as the South-Eastern. It is a well-known fact that the north-country poultry-fanciers manage their railway carriage better than the southern. It is surprising to find how far they make a shilling go, and we have frequently heard Lancashire and Yorkshire fanciers say that the lines of railway in the south near to London would soon choke them off from exhibiting; and we can well remember hearing a large exhibitor say that it cost him a great deal more to get his baskets from London to the Crystal Palace than it did from Lancashire to London. We should like Mr. Beldon or Mr. Walker to come down south for a few months and stir up the officials at the southern stations, and see what they could do.

We have experienced over and over again the annoyance of birds going wrong and being mis-sent. This, however, is a grievance which can be remedied, for it lies in the power of all exhibitors to do something here. We quite know it is very long

and tedious work getting any compensation, but it has been done, and we have gained it ourselves. It is not the value of the redress so much, however, as it is that we hear from the highest possible authority that the very fact of claiming compensation is so thoroughly seen into and investigated at the head office that all the officials of the district are put, so to speak, on the *qui vive* against the same thing happening again; and although the aggrieved party may apparently recover very little, he in reality benefits the cause greatly by making the disturbance. We would urge on all, therefore, who experience loss by wilful carelessness on the part of any company to write at once to the manager of that company and have the case thoroughly sifted to the bottom, which can and will be done. This mode of procedure will do the poultry fancy 50 per cent. more good than the mere airing of troubles and grievances of the kind in the poultry newspapers.

We believe many exhibitors leave the dispatch of their baskets to the last train which can possibly bring them to the show ground in time. This is a most foolish plan, for at junctions, or at places where the birds have to be changed from one company's line to another, a delay is certain to follow, and the birds consequently often arrive "too late for competition." We quite believe this need not happen as often as it does, but there is no one present generally to urge the importance of the birds being forwarded by any particular trains. The other day when we were talking of poultry clubs and the good they might do, some one said that they would be the means of getting the companies to reduce their rates and convey the baskets cheaper. We do not believe any amount of clubs would perform this, and we said so. The utmost they could do would be to have the birds returned free on some lines, and this those companies which we named will generally do if the secretary will point out that it will be to their advantage; but there is a point in which we think a poultry club could really be of value, and that is in appointing some responsible person to wait at the chief junctions on the eve of any important poultry show. This person need not be a fancier; any man of the locality who can be depended upon would be able to do the work, for he would only have to watch the trains coming in and see that all the birds which had to be changed were carefully handled and speedily forwarded. The club funds would "pay the piper," and fanciers would feel greater ease and comfort for the safe and due arrival of their birds. Not only are birds at stations allowed to stand about on draughty platforms, but they often get terribly knocked about as well. We could quote case after case but have not space, for only the other day at Portsmouth we saw some very rough handling, and such a person as we desire at the stations would greatly prevent this. We speak with certainty of the success of some such plan, for a show in which we are deeply interested, at its own expense sends, or arranges for, men to be at the two principal junctions near at hand, and this exhibition finds it not only of benefit to its patrons but to itself as well, for this proceeding is the means of getting the birds in the show ground earlier, and so the labour is not so heavy in the late hours of night. Even without a poultry club some such arrangement as we advocate could thus be made, and we really think the few shillings expended would be money well laid out by many committees, more especially by those who are connected with shows held on loop lines or in out-of-the-way places.

While writing on the railway journeys of poultry we would ask, Who pockets the shillings and sixpences for conveying birds to and from the place of show? After heavy carriage is paid and the birds are properly booked we consider it simply monstrous to charge at all for moving the birds to the show ground; but when it comes to paying 1s. a basket for having one removed just across the street, as occurred the other day at a Devonshire show, we call it nothing short of robbery. We would ask exhibitors to see into this, for it seems to be becoming a general plan, and we would urge on committees to arrange differently for their own interests. The cases we could quote of baskets being paid at one end and charged for at the other are legion, as, too, are cases of baskets costing one sum to go to an exhibition, and perhaps double the amount when they return; but we would only once more urge upon those who are so wronged to apply at once to the chief office of the company and have the matter looked into, for by this means a stir is made among the aggressors, and they are more on their guard in future.

This is a subject on which a great deal more might be said, but in leaving it for the present we would beg exhibitors to see, when possible, that their baskets are not placed in the vans too near to open-mouthed dogs also journeying to the same goal. Over and over again this takes place, and over and over again a valuable bird is killed. Mr. Pares lost his hero this way, and so have many others. In no way advocating the muzzling of dogs when on their journeys, we would only suggest that in trains where many packages of dogs and poultry are expected the secretary should write to the starting place of such trains and state that a heavy load may be expected, so that proper vans may be attached for the dogs and poultry. This may some-

times remove the difficulty of their having to travel together and run the risk of death or wounds.—W.

## TRURO POULTRY SHOW.

THIS Exhibition was held in a large marquee on the town green, and was apparently a success in every way. The officials were courteous, and Mr. Hodson's awards in most cases satisfactory.

The Coloured *Dorkings* mustered a dozen pens, and we quite approved of the winners. In the next *Dorking* class we could not find the first-prize birds in our catalogue, but learned they belonged to Lady Vivian. They were a fair pen of Whites. *Spanish* were excellent, and here came the cup for the best pen in the Show. We fancy one or two of the cocks here would have been passed over by some of our judges, as we think the scissors had been at work on the back of the comb. In *Cochins*, Partridge, the first-prize pen were a showy pair and good in colour, while an admirable pen of Whites won in the next class. Mr. Whitehead's second were also good, but he wants a better hen. Mr. Woodgate's four *Cochin* pens were all empty, a mistake having occurred with his labels. *Minorcas* were not so good as we expected to find; the first were Blacks, but of fair merit only. In *Game* we could have found several good single birds, but they were badly mated, and a good hen would have a poor cock, or *vice versa*, notably so the first Brown Reds, while in *Duckwings* the cock was superior to the hen. A good pen of *Malay* chickens, large and bright in feather, won first, and we were glad to see the young stock to the front. *Brahmas* only mustered three pens, a good pen of Lights being first. In *Hamburghs* we liked the first Silver-pencilled, for the hen was clear in markings, and the cock's tail good. Silvers of good quality also won in the Spangled variety. *Polands* were most noticeable for the great merit of the White-crested Blacks. It was very near between the first two pens, and we are not at all sure that we did not like the second-prize pen best, for the hen in this pen was simply admirable; third went to fair Silvers. *Game Bantams* were moderate, a good pen of Black Reds securing the first prize, while in the next class good Blacks were first and second. The Variety class was interesting; but the French, which won most of the prizes, should have had a class to themselves. We thought the very highly commended Silky chickens might have been in the list; good Black *Hamburghs* were first. A fine Black Red won in single cocks; he had much style and form about him. The *Ducks* were moderate; a large pair of Rouen ducklings secured first in their class.

*Pigeons* brought very small classes. The cup went to Carriers with fine head properties, and we thought the awards good. In *Pouters* Blues were first, with very fair length of feather. Two fair Fans had the class and prizes together, while *Jacobins* nearly did the same. In this class a moderate pair of Reds secured first place. Blue *Dragoons* won first, closely pressed by the second-prize pen, which were also Blues: while in the Variety class *Owls* were first and third, the former White African and the second Silver; second going to *Antwerps* of good quality; pen 200 (Tyerman) were fair *Trumpeters*.

We furnish the list of prizes below:—

POULTRY.—*DORKINGS*.—Coloured.—1 and 2, E. Burton. 3, H. Slade. Any other variety.—1, Lady Vivian. 2, J. H. Nicholls. *SPANISH*.—Cup and 3, J. Boulton. *GAME*.—Black Red.—1, E. Williamson, jun. 2, J. Cardell. 3, G. Dash. Brown Red.—1, J. Cardell. 2, H. Browne. 3, C. E. Pope. Any other variety.—1, T. J. Lobb. 2, H. Feast. 3, H. Browne. *COCHINS*.—Partridge and Brown.—1, G. Lias. 2, J. H. Nicholls. 3, A. C. Travers. Any other variety.—1, Rev. G. Watson. 2, J. N. Whitehead. 3, H. Feast. *vhc*. S. R. Harris. *MINORCAS*.—1, Rev. G. Watson. 2, J. H. Nicholls. 3, J. Thomas. *MALAYS*.—1, W. T. Lecher. 2, J. Pomroy. 3, H. Feast. *BRAHMAS*.—1, Mrs. J. F. Holmes. 2, J. H. Nicholls. 3, W. Burns. *HAMBURGHS*.—Gold and Silver-pencilled.—1, N. Barter. 2, J. R. Herwood. 3, J. Knight, jun. Gold and Silver-spangled.—1, H. Feast. 2, Mrs. S. R. Harris. 3, N. Barter. *POLANDS*.—1, G. Lias. 2, T. Norwood. 3, Mrs. S. R. Harris. *BANTAMS*.—Game.—1, R. Y. Ardagh. 2 and 3, T. V. Bice. Any other variety.—1, F. Temple. 2, J. Mayo. 3, J. Driscoll. *vhc*. R. S. S. Woodgate. ANY OTHER VARIETY.—1, H. Feast. 2, J. H. Nicholls. 3, W. Hamlyn. ANY VARIETY.—Cock.—1, E. C. Pope. 2, J. Bond. 3, J. Beard, jun. *vhc*. J. Westcott. SELLING CLASS.—1, J. Honey. 2, E. Macey. 3, W. Hamlyn. *DUCKS*.—Aylesbury.—1 and 2, S. R. Harris. Rouen.—1, J. H. Hoit. 2, W. H. Coppleson. *PIGEONS*.—CARRIERS.—1, Cud. and *vhc*. E. Burton. Cock.—1 and 2, E. Burton. *POUTERS*.—1, Mrs. J. F. Holmes. 2, J. Broad *vhc*. F. Beck. *TUMBLERS*.—1, H. Yardley. 2, F. Beck. *FANTAILS*.—1, J. L. Smith. 2, H. Yardley. *JACOBIANS*.—1, J. L. Smith. 2, T. Hendra. *DRAGONS*.—1, H. Yardley. 2, E. Burton. *TURBETS*.—1, J. L. Smith. 2, Mrs. Hutchinson. *BARBS*.—1, H. Yardley. 2, E. Burton. ANY OTHER VARIETY.—1, F. Beck. 2, R. T. Harris. 3, J. Lamacraft.

## SNAITH SHOW OF POULTRY, &c.

THE annual Show was held at Snaith on the 13th inst. The grounds in which this Show is held are unsurpassed for such a purpose, the long spreading forest trees proving a most welcome shade from the scorching rays of the sun. For the poultry, &c., a capital marquee was provided, and Turner's pens were used. With a fair kind of schedule the Show improves from year to year in both entries and quality. *Game* headed the list, but with the exception of the first-prize Brown Red and the second-prize hen they were poor. *Spanish* very good, the cup going to the first, as the best pen in the Show. In *Cochins* first were Buff and second White. *Hamburghs* were very good, the Gold-

and that it is useless to transfer them. Some crossings would, perhaps, be useful."

I will quote another paragraph from the letter, which closely agrees with Mr. Pettigrew's teaching. "The great question of the day in our Switzerland, as in France, Germany, and America, is that of mobilism or fixism [the systems of fixed or moveable combs]. Mobilism has the incontestable advantages of offering facility for theoretical experiment and the formation of artificial swarms; but is it superior or even equal to fixism with regard to the production of honey? I doubt it a little, because bees do not like to be disturbed in their labours, which always occurs more or less when moveable frames are used."—J. H. ELDRIDGE, *Norwich*.

### SEARCHING FOR QUEENS.

"In uniting swarms can Mr. Pettigrew or some other correspondent suggest a method of disposing of the old queen other than putting one's hand into a crawling mass of bees to seek and pick her out, which is anything but a pleasing process to contemplate, especially to any timid person?"—THOMAS WATTS."

MR. WATTS has done well to put this question, which is of considerable importance in the interests of practical and profitable management of bees; and it is to be hoped that some one of our readers may be able to suggest a simpler and better method of ridding bees or hives of their old queens than the one I have followed and recommended. Many bee-keepers who adopt our way of managing bees inform me that they can do everything I advise but finding the queen in the crawling mass of a driven swarm; and many who have seen me find the queen, and the way in which it is done, have become as expert, clever, and courageous at this work as it is possible for anyone to become. The other day a company of ladies and gentlemen came by arrangement to see bees swarmed artificially; but when I saw the queen and desired them to come near to see her, they would not from sheer timidity. It does require a certain amount of courage and confidence to turn up a hive and look amongst its crawling inmates, and to drive them into an empty hive and peer amongst them till the queen is seen. It requires as much courage to remove bars of comb covered with bees from bar-framers; and many become expert at this.

For the encouragement of all let me say that bees mastered and driven into empty hives are generally very quiet and seldom sting. In the hands of courageous people the work is simple and easily done. To find the queen some apiarians shake the bees out on sheets; but we think this is a very disagreeable roundabout mode of operating. When we have a great many swarms to unite to stocks in autumn possessing young queens, we divide the swarms into three or four lots each by putting them into empty hives. Of course the queen of a swarm can be in one lot only, which settles quietly in a cluster. All the rest speedily discover their loss, and manifest it in a great uproar and tumult; and as soon as the uproar commences the bees are united to the stocks. Then the queens are easily found and destroyed among the bees of the small clusters. As soon as seen they are destroyed, and the bees are given like the rest to the stocks. But our usual mode is to drive all the bees from a honey hive, and if its queen is old to destroy it before they are united to one or two stocks. To us nothing can be more simple or easy than this. We shall be glad if our readers will favour us with their opinions and experiences. Some bee-keepers use puff-ball, some chloroform, in the process of uniting swarms. We shall be pleased if our correspondents ventilate the question fully.—A. PETTIGREW.

### OUR LETTER BOX.

NEW POULTRY HOUSE (*E. W.*).—As you are fortunate enough to speak of space as unlimited, we shall deal accordingly. For a hundred fowls we would have a house 80 feet long by 20 wide, and at least 12 feet high. It should be well lighted both in the roof and at the sides. The door should be in a corner, and the perches (2 feet from the ground) should not be in a line with the door or any other place where there is a draught. The flooring must be of earth well rammed down, and should slant every way to the door to facilitate cleaning. The laying boxes may be against the wall or boarding in a line with the door. There must be a separate house for sitting. The perches should rest on a ledge fastened to the wall at one end, and on moveable tressles the other. This is convenient for moving, and as soon as the fowls are out the perches should be removed and the house cleansed. A heap of dust is a good thing in a house, and it may be kept perfectly sweet and clean. Dust is a fowl's bath. Duck and Geese must not roost with fowls. If they do you will soon have disease. If you have a farmyard let them roost anywhere; if you have not, any place will do. A lean-to, an old calf pen, an unused pigsty, any such place will do for Ducks and Geese. They defest order and cleanliness, and we believe they never thrive so well as when they are permitted to follow their own dirty habits.

EXHIBITIONS OF HONEY (*J. E. B.*).—The best time for an exhibition of honey, &c., is about the beginning of September. The middle of the month is the best time where bees are removed to the moors, for heather yields honey till about the 10th of September. For the encouragement of bee-keeping and bee-culture prizes at small horticultural and agricultural meetings should be offered, 1st, for the greatest results in weight from one stock of bees; 2nd, for best and heaviest swarm of the current season; 3rd, for best super of honeycomb. The first-named deserves a prize of greater value than the other two. A lady in the north of Scotland gives annually a prize for the heaviest first swarm, and there is generally a keen

contest for it. For country exhibitions in England the fewer conditions laid down the better, but it should be understood that the exhibits are to be the natural products of the bees from the flowers of the fields and forests.

TAKING SUPERS (*J. O. W.*).—In taking the super from your old hive at the end of this month, first cut it from the top of the hive by drawing a piece of string or wire between them, raise the super by thin wedges about a quarter of an inch, and leave it so raised for about an hour to enable the bees to lick all the honey from the broken cells. Get the bees from the super into the old hive, and then drive all into an empty hive. As you have no super on the 18-inch hive which you wish to take, drive them, too, about the end of this month into another empty hive, and rapidly feed both into stocks by giving each swarm about 15 lbs. of good sugar boiled in 14 lbs. of water, or mixed at the rate of 1 lb. of sugar with one pint of water, and boiled for two or three minutes. Let each swarm have 2 lbs. of syrup at least every night. From the syrup thus given the bees will rapidly build combs, and not only store up food, but produce a hatch of young brood or bees that will make the stocks strong for winter. For feeding swarms rapidly we have never seen or heard of an instrument equal to a feeding-board, which is simply a floor-board with a dish or trough in it. Our feeding trough holds three quarts of syrup, and can be filled from the outside through a funnel and tube. A large flower-pot saucer let into a board, or placed on it, answers very well if plenty of chips of wood or short straws be placed in it to keep the bees from being drowned. We are glad to learn that you and your friends are gathering information and encouragement from the pages of this Journal, and find yourselves "emerging out of darkness into light." All will be clear and easy to you by-and-by.

### METEOROLOGICAL OBSERVATIONS.

### REMARKS.

- 12th.—Very fine, bright, pleasant day and night.  
 13th.—A brilliant summer day, very hot.  
 14th.—Fine, but rather hazy in the morning; very warm, close, and storm-like in afternoon and early evening, but fine right.  
 15th.—Hazy in morning, very fine all day, but intensely hot—in fact, the hottest day this summer, thermometer reaching 92.6° in shade.  
 16th.—Very fine and very hot, and both feeling close and storm-like, and looking so about 7 p.m.  
 17th.—Another hot day, but towards the evening there was a little movement in the air (which has been very stagnant hitherto in the heat), and the heat became more bearable.  
 18th.—Another very fine day, but the breeze tempered the heat, and so the weather was much more pleasant.  
 Very fine rainless summer week, the air very dry, and the range of temperature considerable. The temperature on the 15th, 92.6°, unusual, but by no means unprecedented.—G. J. SYMONS.

### COVENT GARDEN MARKET.—JULY 19.

THE present hot weather is proving too much for all kinds of soft fruit, and supply is consequently falling off. Prices somewhat higher than last week. Hothouse fruit is lower in consequence of the close of the London season, though best samples of Grapes and Peaches maintain their full value.

From observations taken near London during forty-three years, the average day temperature of the week is 75.4°; and its night temperature 50.4°.

## PANSIES FROM SEED.

FOR general decorative purposes a more useful flower or a more lasting one is not to be found than the Pansy. Its beauty is unquestionable; it does not grow rampant, but takes up little room. It is available for arrangement in a multiplicity of forms—in single patches, in beds, or in lines in borders. The colours planted in rows to harmonise, in a circular or other shaped bed will be found to look well. I do not mean the self-

coloured varieties in white, yellow, blue, and black, but the show kinds in self, yellow, and white grounds; whilst the fancy varieties make splendid beds of many shades of colour.

Setting aside the harmony sought by an arrangement of distinct colours, I consider a mixed bed of Pansies in which there is such a blending of colour as to produce no decisive or prevailing hue most attractive. The flowers are so varied, and yet each plant maintains its individuality, and a rich mass of floral beauty is provided calculated to fill the eye at a distance. In a bed of mixed Pansies we have beauty of form, extreme diversification, and richly-varied colours. The eye has no greater love than for colour, especially the colours of nature: hence the desire of producing coloured representations of objects exciting our interest and admiration, and yet we are not to abstain from the study of a subject because it presents variable phenomena. Of this class are seedling florists' flowers, especially Pansies, which are so sportive that many varieties will come from one pod of seed; so that if seed is had from a few varieties there is no lack in colour and shades, which in form, substance, and marking cannot, if good seed be had, fail to afford pleasure to all lovers of plants. To those who care to examine a flower for its beauty I know of none in which it is to be found more abundantly than the Pansy. And when we consider that for the same money as would purchase a good variety as much seed may be purchased as will afford plants in variety to stock a good breadth of ground, I am surprised that this and kindred subjects are not more generally raised from seed, most persons being much more proud of a collection of plants of their own raising than of a stock wholly produced by others. Besides Pansies from cuttings when apparently growing satisfactorily suddenly droop, become paralysed, and die; but with plants from seed this liability of the Pansy to sudden collapse is reduced to a minimum, and in not too rich soil is altogether avoided.

The raising of the Pansy from seed is a very simple process. I usually sow about the middle of July to early in August in light moderately rich soil on a sheltered border in rows about 3 inches apart, scattering the seeds in the drills rather thinly, covering lightly with fine soil, and keeping moist to insure the certain germination of the seeds. By the end of September the plants will be fit to put out in beds, which should be deeply dug and liberally manured, a well-ameliorated soil being of more

consequence than a rich one. I allow a distance of a foot between the rows, and of 9 inches in the rows from plant to plant. Plants from the late July or early August sowing will commence flowering with the mild weather of spring and continue up to July or August.

A summer bloom is best had by seeds sown the first fortnight of September in a warm corner at the bottom of a wall or other shelter, transplanting to the flowering quarter in spring. For a late summer and autumn bloom seed should be sown in March in boxes or pans, affording a little heat until the plants appear, when all the air possible should be admitted, and after being hardened-off planted out where intended to bloom.

An open situation is the only one suitable; but if the situation be such as to afford shade in the middle of the day without being overhung by trees, such a position is desirable in dry hot weather; and though a free soil is requisite with freedom from stagnant moisture no plant is more grateful for coolness and moisture than this.

To obtain a succession of bloom cut with discretion a portion of the branches near the stem, and in their stead will arise young shoots. This must be done before the plants are much exhausted, commencing as soon as the plants are well established in size, and if care be taken to occasionally pick off the flower stems as the flowers fade the continuance and superiority of the bloom will be greatly furthered. If seed be wanted it will not, of course, answer to remove the pods; but I would not advise anyone to save seed except from the best flowers and first-class varieties, and then, unless cross-breeding be resorted to, little improvement can be looked for, as the climax of perfection is about attained by the usual process of selection of seed from the best flowers of first-class varieties.

Now, in crossing a few hints may be found serviceable. Select the very best flowers only for seeding, and the same in the flowers from whence the pollen is to be taken, taking care that for white grounds both parents are of one shade in the ground colour, yellow grounds the same, also selfs. When the seed-bearing flower is rather less than half expanded remove the lower petal of the flower altogether, which will keep it from being fertilised by its own pollen, and from the male flower the stigma may be removed, which will assist the development of the stamens, allowing all the petals to remain. When the stigma is in a fitting condition for impregnation—noticeable by its concavity and viscid appearance—search for ripe pollen, which will be found embedded in the hollow curve of the lower petal near the extreme point. Pulling off this petal very gently take it to the intended seed-bearer, and gently from the base guide the apex of the stigma all along the hollow of the pollen-containing petal, in which way it is hardly possible to fail in filling the mouth of the pistil with ripened pollen. If the stigma be in proper condition the swelling of the ovary will witness the completion of fertilisation. The pollen may be taken from the extracted petal and applied to the stigma with a small camel-hair pencil. I do not think it needful to remove the stamens from the seed-bearer to prevent self-impreg-

nation, nor to guard the stigma from fertilisation by insects, though it may not be undesirable to do so.

I know not but everybody is aware of the chasteness of Pansies in a cut state. Done up in little bunches of half a dozen, and surrounded with leaves of *Viola pedata* or the Pheasant's Foot *Pelargonium* (*P. denticulatum*), they are really charming, it being astonishing what a quantity and continuance of flowers these plants afford when the flowers are picked as they expand and the plants kept from seeding.

I certainly advise everyone with but a few square yards of ground to invest in a packet of seed of show and another of fancy (Belgian or French) Pansy, convinced that no plants will for a similar expenditure afford such a profusion of bloom for so lengthened a period in so much variety, and of enjoyment to the purchaser.—G. ABBEY.

### PROTECTING FRUIT.

IN the spring time there is generally a great deal of labour and expense devoted to the protection of fruit blossom from frost and cold winds, but in many instances there is quite as much attention required to protect the fruit when ripe and ripening from birds and other destroyers. About this time, and further on in the season as fruit becomes ripe, it is surprising how very quickly a large quantity will be destroyed if not securely protected. Market gardeners do not generally suffer so much loss in this way as their private friends do. The productions of the former are never allowed to hang long after they are fit for eating; and as most market gardens are in the neighbourhood of towns, birds and other fruit pests are not so plentiful as they are in well-wooded country localities. Small outdoor fruits, such as Strawberries, Currants, and Gooseberries, are much eaten by birds when they have the slightest access to them.

As protection for these nothing better can be used than herring nets. In well-arranged gardens permanent provision is made for putting on these when required. This generally consists in driving stubs 4 or 5 feet long into the ground about 10 or 12 feet apart, and fixing long rails on the top so as to reach from post to post. When the fruit is gaining maturity the nets are stretched over the top of these rafters and fixed around the edge with wooden pegs. When any fruit is wanted it is only necessary to pull out a few of the pegs, lift the net, and walk underneath. In many instances the nets are allowed to rest on the tops of the bushes; but this is a bad plan, as the point shoots are not only injured, but with such as Red Currants the birds can often sit on the net and pick the fruit through. Besides, when fruit has to be gathered the whole net has to be removed and again replaced. Strawberries are often protected in the same way, the net being allowed to lie on the top of the leaves when it has to be dragged about before any fruit can be obtained. Fixing rails may seem rather expensive at first, but it is the most satisfactory way in the end. If the rails are put up when a young plantation of such as Gooseberries or Currants are made they will last as long as the bushes remain in a prime-bearing state, and do not interfere in the least with the growth or anything which may require doing about the bushes. "Herding," or scaring the birds from small fruits, is a very tedious operation, of which we had a good deal of experience at one time; but it is only where there are plenty of "hands" that this can be done, and then it is not so efficient as the nets.

Cherries are generally very subject to the attack of birds, and as this fruit is mostly grown on walls netting must again be resorted to. The net should be of sufficient width to reach from the top to the bottom of the wall. In fixing it should be nailed along the top of the wall, and allowed to hang over. There are two very good ways of holding the net a distance from the tree. The one is to drive long stakes into the ground 4 or 5 feet apart and about 1½ foot from the wall, and peg the net down the outside of these; the other, but not such a convenient way, is to fix pieces of stick here and there in the face of the wall with a forked projecting end about a foot from the wall, and let the net rest against this.

Peaches, Nectarines, Apricots, Plums, and the finer kinds of Pears are not only eaten by birds, but wasps and large flies do much harm to the ripe fruit. To prevent this very closely meshed netting has to be used. This should be put on in the same way as the other nets on the walls; but this kind of netting should never be used until the fruit is all but ripe, as it shades from the sun very much, and to do this while the fruit is not nearly ripe the flavour is very liable

to be deficient. Wasps are often more destructive on stone fruits than any other kind of pest. Like birds, they are only plentiful where there are many woods. Any trees on which there are only a few fruits may have them protected by placing a small piece of netting over each fruit. Isolated standard trees should be surrounded with a few stakes and wrapped round with netting. In all cases where permanent supports can be fixed this should be done, as they are not only convenient and useful when the fruit is ripening, but in spring when the blossom requires to be sheltered they are of great assistance.

Tender indoor fruits, especially Grapes and Peaches, are greedily devoured by wasps, and sometimes by birds. The very fine-meshed netting or tiffany should be nailed over all the ventilators which are opened, as in the outside. This is the best plan which can be adopted. Bunches of Grapes are sometimes tied in paper bags. In this the fruit cannot be seen, and unless the bag is taken off every other day, which spoils the bloom, decay may take place before it is noticed.

Bottles of sour beer are often hung up amongst Grapes. A few wasps and flies may find their way into them, but when once they are admitted into the vinery the most of them seem to prefer the fruit.—J. MUR.

### IVY.

IVY is one of the most common, yet certainly the most useful, of all climbing plants. Its hardness, its evergreen character, its free growth, its close dense habit, its glossy foliage, its chaste venation, and the effective variegation of some of the varieties being commendatory qualities of the highest order. Ivy is applicable for many purposes of shelter and modes of decoration. Used as a covering for screens and rustic fences it affords perfect shelter against cutting winds, and also from sun; and as screens for the drawing-room it breaks alike draughts of heat or cold without any material injury accruing to itself. For covering walls, buildings, or ruins it is well known to be the best of all plants, and instead of making such walls and buildings wet it has really the opposite effect of making them more dry than before.

In the garden Ivy is more extensively used than formerly—the green free-growing kinds as edgings to walks; the closer-growing kinds as coverings for banks, rockeries, and roeteries; and the choicer sorts for staircase, hall, corridor, and even conservatory decoration. For all these purposes Ivy is particularly worthy of being employed, while for covering low walls in almost all sorts of positions and with all aspects a collection of the choice variegated kinds are extremely ornamental.

As pot plants for associating with groups of flowering plants well-trained specimens of Ivy are not only amongst the finest, but are the most easily preserved and permanent of plants. How effective are pyramids of Ivy was strikingly exemplified at the great Show at South Kensington last year, when the nurserymen made the grand and spontaneous offering of the best of their collections, producing an exhibition which has not been equalled in London for many years. Fine as were all the collections then exhibited—rich, valuable, and rare as were many of the plants composing the groups—yet no bank was more strikingly ornamental and won higher encomiums of praise than the group of specimen Ivies associated with *Lilium auratum* from Mr. Turner of Slough.

Ivies in a small state are also admirable for the furnishing of window boxes, balconies, hanging baskets for indoors and out, and the variegated kinds for lively edgings for flower beds in winter. The uses of this plant in its several varieties are so manifold that there is no wonder that the demand for plants is increasing year by year, and very large supplies have to be provided to meet the ever-growing requirements for this now popular plant. I was so struck with the effect of the fine plants noted above that I obtained a few, and nothing in my garden has afforded me more pleasure than my collection of Ivies, and few plants are more admired by my friends and visitors. I have the satisfaction, too, of feeling that they are so safely established that no weather will injure them, but that they will improve year by year with a minimum share of attention being bestowed on them. Some sorts are slow growers, but that is an advantage for many purposes of decoration, admitting the plants to places where luxuriant growers would be quite unsuitable.

To those having much decoration to provide for special occasions, and are in an atmosphere unsuitable for the majority of plants, I can imagine no store more useful than a reserve

of Ivies in pots plunged in ashes or soil in the garden. They can be drawn for on any occasion for which they may be required, and after serving their purpose may be returned to the store for future use.

A dozen effective Ivies which are useful for various purposes I select from those now growing in my garden; but let me say that for covering surfaces, and especially under trees and for forming edgings to walks, the old Irish Ivy (*Hedera helix canariensis*), is unsurpassable. The sorts which I find very ornamental are the following:—

*H. Regneriana*.—Leaves large, green, glossy, leathery, and but slightly lobed. A noble Ivy for covering walls quickly, being very bold and handsome.

*H. pedata*.—Leaves hastate, small, sharply lobed, green with distinct silvery-grey veins; a good grower and climber; suitable for walls, pots, and almost all purposes of decoration. One of the most useful.

*H. latifolia maculata*.—Leaves large, green, heavily blotched with white. A very free grower, and admirable for dark places in shrubberies, either for covering walls or trellises or for trailing over the surface of the ground.

*H. lobata major*.—Leaves medium-sized, bluntly lobed; a cheerful green, with clearly marked veins. A very useful free-growing variety.

*H. minor maculata*.—Leaves very small, perfectly mottled; habit close; plant of free growth. Useful for margins.

*H. sub-lutea*.—Leaves small, irregular, not lobed; centre green, edged and flaked with white and yellow. Distinct but not vigorous.

*H. rhomboidea*.—Leaves medium, almost oval; very rich green with clear veins. A good grower; very distinct and effective.

*H. marginata grandis*.—Leaves medium-sized, rich green, broadly margined with ivory white. A very free grower, and valuable for pots, walls, or edgings.

*H. marginata rubra*.—Leaves small, two shades of green, broadly edged with white and flaked with pink. Attractive.

*H. marginata major*.—Leaves slightly lobed, deep green, mottled with light green and margined with creamy white; veins clear. Effective and a good grower.

*H. angulata*.—Leaves medium, very rich green, rather deeply lobed; veins distinct. Not a good climber, but effective for many purposes of decoration.

*H. chrysophylla*.—Medium grower; leaves green, some of them mottled with yellow, others entirely yellow. Very distinct, and effective for pots, low walls, rockwork, &c.—J.

### ROSE JUDGING.

NEVER has our national flower been grown so extensively and exhibited so gloriously as in the season now passing. In many stands the difficulty has not been to pick out good, but inferior blooms, so uniformly excellent have been the collections.

Rose-growing is not only pleasurable in itself, but fosters good feeling, promotes good fellowship, and calls into action worthy qualities. There is nothing churlish about rosarians; they not only desire that others should see and enjoy their "blooms," but at great cost and labour travel with them, it may be, a hundred miles and place them on the exhibition tables.

In the exhibiting of no flower is there such a heartiness as in exhibiting Roses. Each exhibitor hopes to win—he would not be a worthy exhibitor if he did not—but there are no "better losers" than among rosarians when a verdict is rightly given. Some exhibitors are more elated than others when successful, and there are degrees of expressed disappointment on losing. It is stated that on the Rev. Reynolds Hole being "lectured" by an unsuccessful exhibitor, who thought himself or his Roses "badly judged," that Mr. Hole coolly replied, "My friend, I always said if ever I went crazed it would be over the Rose."

But considering the difficulty of judging Roses, the differences of taste, and the number of exhibitors, it is proverbial that there are very few "scenes" in the Rose court, and that because those who indulge in the gentle art of Rose-growing are gentle-men. Yet there are not many shows at which some exception is not made to the correctness of the verdict in some class or other. That the judges are impartial no one doubts, and they are admitted to "know a Rose when they see one." But knowing a Rose well is not sufficient to constitute a gentleman a judge. There are those who can analyse the merits of a Rose perfectly, and can pick out the best half-dozen or dozen

blooms with certainty, but who become quite bewildered when they have to adjudicate on half a dozen "seventy-twos" and as many "forty-eight trebles."

In these large classes and when the competition is keen there are very few amateur growers who can grasp the qualities of the several collections. There are not many exhibitions which do not betray some error in judging, and at times the awards are changed after they have been made. The judges have long and carefully balanced the collections, and have decided as they think rightly, when someone sees at a glance that an error has been committed, and points it out in a few words that carry conviction, and the mistake is sometimes rectified. At some shows it is observable that freshness and quality have carried the palm, and at others size has triumphed, according to the "tastes" of the adjudicators. There does not appear to be quite an accepted standard in Rose judging, and perhaps it would be difficult to define one: hence it is that judging must be a matter of taste, and the more important it becomes that the adjudicators should not only "know a Rose," but who can comprehend as if intuitively the relative merits of classes which embrace from three hundred to eight hundred blooms.

There are few except those who spend as it were their lives among the Roses, who can judge large collections accurately. I have made a point of noticing the remarks of the working rosarians—the men who have grown and staged Roses for years—when they have entered a show to see the verdicts. It is surprising how "unerring is the instinct" of these men, and if a mistake has been made how quickly one after the other will detect it. It is pretty certain that the professional growers of Roses are the best judges of large collections, and I think the time has arrived when at least one professional judge should preside over the important classes in every great show. There are those who do not now enter the lists in competition, yet who are thorough masters of the art of judging, whose services might advantageously be brought into requisition. There are great growers in the north who do not exhibit in the south, and *vice versa*, who might be engaged to adjudicate, giving them remuneration proportionate to their standing and skill. One thorough good judge will not only judge more accurately than the majority of amateurs, but will do his work more quickly. Rose-growing has attained such a state of perfection, the collections are so large and numerous, and their merits are so nearly balanced, that only judges of great standing can be expected to give safe and satisfactory verdicts. At any rate it is highly important that special care be exercised in the selection of judges, for it is a great mistake to think that all lovers of Roses and enthusiastic admirers are competent to adjudicate in the great classes at our large shows.

In judging the judging too, for there is necessarily much of that, one cannot be too careful. Nothing can be more absurd than to differ from the awards two hours after they have been made. At a recent show a judge, one of the best in England, was "button-holed" and brought face to face with the work he had done two hours previously. "Which now as a Rose-grower and a honest man," asked his interrogator, "which of these collections do you mean to say is the best?" "This one of course," after a momentary glance at the boxes, replied the adjudicator, pointing to the second-prize collection. "Then why," retorted the exhibitor, "did you not give it first?" "Because," said the judge, "it did not deserve it. I awarded the prize to the best collection at eleven o'clock, and now it is one o'clock."

There is a great deal of reason in that reply, and it may well be kept in mind when one is inclined to judge the judging. In even half an hour after judging blooms will lose their quality, and if on-lookers would well consider the question of "time" in connection with quality there would be fewer remarks on "bad judging." But one thing is clear, that in adjudicating on the magnificent displays of modern times the judges cannot be too thoroughly, practically, and intimately acquainted not only with Roses as such, but with Roses in the immense numbers and of the high quality that are now staged. Where twenty can be found to judge in the "twenty-fours," not half a dozen deal competently with close collections of "seventy-twos."—A SECRETARY.

### FLOWERS WITH FERNS.

THE following is a plan now used by me in the gardens at Hainton Hall for filling pots (which are placed in vases), with cut flowers and Ferns.

At the time of potting Maidenhair and other Ferns three-

or four small vials are inserted in the earth, which vials should be filled with water and cut flowers inserted at the time they are wanted for decoration. This has a very pretty effect, and the Ferns last much longer than in the ordinary way of cutting the fronds.—JOHN FRISBY.

### MIGNONETTE.

DESERVEDLY popular is this sweet and simple flower, not only in this but in other civilised countries. For this universally admired plant we are indebted to Egypt, but it has long been perfectly at home with us, growing almost everywhere and ripening its seeds perfectly. I say it grows almost everywhere, for there are some singular exceptions—some gardens wherein this plant refuses to thrive, but they are fortunately not numerous. I was once engaged in a garden in Lancashire where it was next to impossible to make two such common plants as Mignonette and the common Laurel grow; and I have known in a few other places how difficult it has been to grow Mignonette satisfactorily in the open garden, and not infrequently have I read records of failures and applications for aid under such circumstances in the columns of the Journal. It is not easy to account for such a free-growing plant as the Mignonette refusing to grow even when the site, soil, and surrounding circumstances are in some degree familiar, much more is it impossible to divine the cause of failure in gardens of which one knows nothing. If I cannot explain the cause of failures which some have to endure, or point out any satisfactory remedy, I can at least offer as some consolation that those who fail fail in good company, and that their failures do not in all probability arise from either ignorance or neglect of those having the charge of the gardens wherein this plant refuses to flourish.

It is not a pleasant theme to report failures in the cultivation of any plant, and it is especially delicate, and in fact almost dangerous, to identify the names of places and of cultivators where and under whose care a given plant cannot be satisfactorily cultivated lest it should be construed as reflecting on the skill of a particular cultivator. Especially is that the case when reference is made to those of rather light calibre. I once made the mistake of referring to the practice in a garden which was fairly good, and giving the gardener rather more credit than he was in strict justice entitled to, but because I did not say he grew many things better than everybody else I received a severe epistolary castigation, which I have carefully preserved as a singular admission of human frailty. But, on the other hand, there are those standing so high in their calling, whose skill is so generally admitted, and whose practice has long been so eminently successful, that there is not the remotest fear that the record of a failure can be regarded as more than what it really is—the simple chronicling of a singular fact, and to think of it in any way as reflecting on personal skill is a palpable absurdity. I do not hesitate to state, therefore, that in one of the finest and best-managed gardens of Britain—a garden wherein I have seen uniformly high practice, and of which the manager's name is a "tower of strength," Mignonette refuses to grow. That garden is at Drumlanrig. In that garden I saw Pines grown as I never saw them before, Grapes in perfection, flowers from aristocratic Orchids to the commoner hardy perennials, and even annuals of almost all kinds, and all grown excellently well, but no Mignonette; therefore I have remarked those who fail fail in good company, and are probably the victims of circumstances incidental to their locality, fixed in character and unalterable. Probably extreme wet has much to do with Mignonette failures, for in one garden in a very wet locality the only place where it flourished at all satisfactorily was in the chinks of a wall. I allude to this now because of some recent inquiries on Mignonette failures, and also because this is the period for preparing for a supply of flowering plants in the winter months.

Mignonette is welcome at any time, but especially in the dull months of the year its delicately-perfumed spikes are coveted and appreciated. As in garden so also it is in pot culture—with some Mignonette grows as freely as do Mustard and Cress, while others have no small trouble in producing robust and healthy plants. But when grown in pots success depends on correct management, and failures are mostly traceable to neglect, or a want of skill or means to apply it.

Mignonette while susceptible of injury by excessive moisture in its early stages is also liable to receive injury by extreme drought. In the summer months especially more failures

arise from the latter than the former mishap. It is not easy to grow Mignonette in pots unless they are plunged in ashes or some other suitable medium. The spongioles are extremely delicate and fine, and shrivel by extreme drought or decay from excessive wet. In both cases the results are the same, and the end failure. If Mignonette is, by fear of damping, so far deprived of water that the foliage turns yellow and the stems become hard, vigorous spikes cannot be produced. The plants must be kept growing freely, and to this end copious supplies of water must be given in dry weather. Plunging the pots, however, conserves moisture, and the plants invariably grow more freely and satisfactorily when the pots are plunged than when they are exposed to the drying influences of the air and extreme changes of temperature. Mignonette, too, rejoices in a good ladder. The soil must be rich and firm, so that the food is not only good, but a large quantity is compressed into a small space.

Clean pots, well drained and firmly filled, or nearly filled, with sound rich soil, and seed sown in them very thinly at the present time, the pots being plunged in ashes and so placed that lights can be placed over them in very wet weather, will, with proper attention to watering, yield a fine crop of Mignonette in the early winter months; and the plants, if kept in a genial temperature and a light house, will continue flowering all through the winter. The plants must be thinned very early (that is of great importance), leaving about five in a 5-inch pot. In these pots the plants will flower perfectly, but if large bushes are required for cutting from throughout the winter the plants must be shifted into larger pots before the seed pots become closely matted with roots; in fact, potting must be done when the roots are in full activity, and when the plants are young and luxuriant. When in this state it is surprising, the weather being dry, how much water Mignonette will not only endure but rejoice in. It is when the plants are quite young, and before the pots are occupied with roots, that large supplies of water are fatal; but the safety valve against this is in plunging the pots, rendering frequent and heavy waterings unnecessary, and protecting the plants against drenching showers.

It is important in growing Mignonette that a pit or frame be entirely devoted to the plants, so that the proper treatment can be given them. It is rarely that success follows when the plants are mixed with other plants.

The present is also a very good time to sow seed for growing single specimens, thinning the seedlings early to the best plant in each pot, and potting-on as required, before the pots are crowded with roots until the plants are finally transferred to their flowering pots. The great object should be to keep the plants growing freely, the shoots soft and stout as Watercresses, and the foliage as large and green as Radishes, then will fine spikes follow in due time.

There are few places where Mignonette in winter is as plentiful as is desirable. Many attempt to grow it and many fail, while others succeed without apparent difficulty. A few common causes of failures are—soil too poor and too light; the seed sown too thickly and the plants not timely thinned; too much water in the earliest stages of growth, and too little when the plants are larger; not plunging the pots; permitting them to be thoroughly drenched with rain, and then when too late placing them under glass and keeping the plants too close and dark. They cannot have too much light and air, and should only have the protection of glass when unfavourable weather—rain or frost—is threatening. Soot water is beneficial when the pots are filled with roots and larger pots cannot be given.

There are different varieties, but any of them if the plants be well grown will give satisfaction. The "giant" becomes a dwarf in the hands of a bad grower, while the "old sort" becomes refreshingly robust when the right treatment is given throughout. In a word, more depends on culture than on the selection of any so-called variety.—W.

[We knew a soil that did not produce Mignonette satisfactorily until some bricklayers' limy rubbish was added.—Eds.]

### CATERPILLARS ON GOOSEBERRY BUSHES.

THERE are various remedies for this destructive insect. A bunch of Gorse, lime, powdered hellebore I think, a sprig of Elder, picking by hand, and there may be sundry others equally efficacious. Would any of your readers who may wear a tolerably thick boot like to try the following very simple process? Give the under side of the bough a sharp and sudden

upward kick, then with the sole plaister the fallen enemy on the ground. If this should be thought too commonplace an implement, I have used a spade; but the other, being always carried about with you, is the most handy.—V.

### IN AND ABOUT CHESTER.

I OWE it to the kindness of the Messrs. A. & F. Dickson that my visit to Chester was so pleasantly employed, and that I am enabled to tell the readers of the Journal something of what may be seen there by those interested in horticulture; while to all who love the olden times there is no city in England which presents so much of real interest as it does. Its quaint old houses, its unique "rows," its old walls, its venerable remains, all tend to make it a city *per se*. One may sit on its walls and muse on the time when the legions of mighty Rome were encamped here and executed works which remain until now, or of the times of those Saxon conquerors who like the rider in the old fable from being helpers became masters, or of those days when these quaint rows were built, and people them with characters which many an old story book has made us familiar with. But we must not dream of the past but think of the present; and here we are now in a part which tells something of the difference between the olden and modern times, for though the Roman legions made fountains and erected altars to the nymphs of the woods, and built temples and aqueducts, we do not hear of their making parks or laying out grounds for the recreation of the citizens. But now in

#### GROSVENOR PARK

one may see a proof of the different tastes of these days, and also of the liberality of that noble house which has been so identified with the city of Chester, and of whose princely place—Eaton Hall, something has been said.

This Park was presented to the city of Chester in the year 1867 by the Marquis of Westminster, father of the present Duke. It is beautifully situated on the banks of the Dee, and from it can be seen the castellated ruins at Beeston and a wide extent of country. There are two main walks about 15 feet wide, one of which is planted with *Cupressus Lawsonii* and *Juniperus chinensis*, the other with fine specimens of the Broad-leaved Holly. The quarry from whence the stones were taken for the boundary wall has been turned into a rock garden, and with a well in the centre. There are various clumps of ornamental trees. The whole was laid out by Mr. Kemp, and the planting executed by Messrs. A. & F. Dickson; while not only did the Marquis of Westminster give the Park but endowed it with £200 a-year for its proper maintenance.

Florist though I am, the most natural style of gardening has a great attraction for me, and alpine and herbaceous plants will always give me a treat which no bedding-out ever does. When therefore I heard that there was a rock garden in the neighbourhood, although my informant could tell me nothing as to its present condition, I was glad to have the opportunity of seeing it.

#### HOOLE PLACE

was formerly the residence of Lady Broughton, by whom the rock garden was formed, and under whom I believe it was well arranged and kept. Sir John Broughton was known well in the neighbourhood of London some years ago as an exhibitor of Azaleas, &c.; Broughtoni was named after him. It at present belongs to Mrs. Hamilton, who manifestly has not the taste of her predecessor. The garden was evidently formed to imitate an alpine valley surrounded by hills; the rockwork being, I should suppose, some 20 feet high and built of a very peculiar and picturesque stone from Gresford, a sort of conglomerate of wood and lime, and I can imagine no better matrix for the numerous lovely alpine plants which have been introduced of late years. But alas! if one wanted to know how not to do it here is a fair example. The whole place is overrun with *Erinus alpinus* (very pretty, but here it was overdone), *Saponaria ocyroides*, *Cerastium*, &c., while Yew trees clipped into formal shapes were planted at various elevations, and bedding *Geraniums*, &c., introduced amongst them. Then the lawn, which might have been made, and I think very likely was made, to represent an alpine valley, is now laid out in formal beds planted with Roses and bedding plants. Had there been simply a lawn to imitate an alpine meadow, and a small stream of water been arranged to run through it, as I think could have been done, the whole would have worn a very different aspect. Amongst the Ferns, which I found doing very well here in the open, was *Adiantum pedatum*. There was in one form or another a good bit of glass about the place,

and in the houses were some plants which one does not always see now-a-days. Some fine plants of that pretty annual *Schizanthus Priestii* were just going out of bloom. The gardener said that he sowed the seed in September, and kept the plants in cold pits until the frost set in, when they are removed to the greenhouse and flower all through the winter. They are graceful and elegant, and answer admirably as cut flowers. The gardener also spoke of *Chrysanthemum Dunnetii* as useful for the same purpose.

Exactly opposite to Hoole Place is

#### HOOLE HALL, THE RESIDENCE OF A. POTTS, Esq.

Very different indeed in character, where gardening in nearly every branch is carried out, from stove and greenhouse plants to even a collection of *Auriculas*. The house is a large, commodious, and square building with a conservatory attached. In this was a large plant of *Dicksonia*, *Lapageria alba*, *Musa Ensete* in fine condition, the old and beautiful *Plumbago capensis*, and a fine plant of *Tacsonia Van-Volxemi* hanging from the roof with its beautiful crimson parachutes. The back wall of a conservatory is never a very sightly aspect, but here it is made very pretty: an artificial rockwork had been placed against it, and in its recesses and nooks had been planted *Adiantums* and other Ferns. The gardens were extensive, and, as I have said, of a very varied character, and alterations are being made which after a little time will add to their appearance. Roses came in for their share of attention, having a place devoted to them, while the fact that there was a collection of *Auriculas* had whetted my curiosity. But, alas! like the rockery at Hoole Place, it was a disappointment. I found the numbers to be small and the kinds few, and those not in the best condition. They were grown in large pots, the old "mugs" of the Lancashire growers, and they were placed in a very hot situation under a north wall. As a rule a northern aspect in summer is what they want, but they had here all the afternoon sun, while the reflection from the wall slate further increased the heat and dryness, and they seemed to me to be in an evil case. I have a difficulty myself in finding shelter for my collection in the summer months, but do manage it under a hedge, which I believe to be far preferable to a wall, the greater coolness and airiness of the situation being in their favour. Bedding-out was just beginning, and, like every other place this year, was backward. The neighbourhood of Chester had suffered very much from drought and cold winds this spring, the genial rains with which we had been favoured in the south not having apparently at this time reached them.

It did not strike me from what I saw and heard that gardening in the neighbourhood of Chester is in a very flourishing condition. I should have expected to have heard of much more than I did, specially where such firms as those of the Messrs. Dickson are there to show people how things ought to be done; and I am the more confirmed in this by observing that according to Hogg's "Horticultural Directory," there is no horticultural society in the town and neighbourhood. I believe that this is a pretty sure index of a languishing condition of gardening taste. Why it should be so it is not for me to say. There are public-spirited people there; there is a resident nobleman whose hand is ever ready to help forward anything that tends to benefit his fellow men; and there is a populous neighbourhood from whence to draw the company by which a flower show is made to pay. It may be that this may meet the eye of some of the readers of "our Journal" in Chester, and if so it may stir them up to do something in the cause we all have at heart; and my own somewhat extended experience goes far to prove that where there is no flower show it is because the taste for flowers is at a low ebb, and that when once a society is started it soon fosters a taste.—D., Deal.

### MRS. PEARSON GRAPE.

MR. DOUGLAS in his lucid description of Mr. Pearson's Nurseries, Chilwell, on page 28, mentioned the new Grape Mrs. Pearson. As I had the opportunity of tasting this Grape in February last I am of opinion that it will eventually prove the best-flavoured late white Grape in cultivation.

I believe Mrs. Pearson is the result of a cross between the true *Alicante* and *Ferdinand de Lesseps*, though I am not sure as to the latter. In appearance it is exactly like an *Alicante*—namely, compact bunches and good-sized berries, set freely on stout short footstalks. In flavour it much resembles *Ferdinand de Lesseps*, but with a stronger Muscat flavour, like a thoroughly

well-ripened Muscat of Alexandria. I can therefore safely predict from what I saw of it that it will prove to be a valuable white companion to Lady Downe's or Alicante.

The Vine appears to be a vigorous grower, judging from the wood it had made the preceding season. As but little artificial heat was used, the berries had not assumed that deep yellow colour characteristic of Golden Queen; but that will easily be remedied by subjecting it to a warmer temperature. Even when grown under the coolest treatment possible the flavour was very rich and satisfying.—A. W., *Lincoln*.

### VERBENAS AS CUT FLOWERS.

NEARLY everything that was exhibited at South Kensington was alluded to in your report of the Show, yet there was one omission—the cut flowers of Verbenas exhibited by Mr. Turner. The Roses at the Show were—well, they were regal; the Carnations and Picotees were splendid, and the trusses of zonal Geraniums were brilliant or gaudy, according to taste; but the Verbenas were charming, or as a lady visitor observed, “sweetly beautiful.” Here we had a greater range of colour than any other collection of flowers afforded—bold, yet chastely formed, and delicately perfumed. White, pink, cerise, scarlet, crimson, maroon, lilac, blue, mauve, and purple were all represented in this attractive collection of Verbenas.

In some places Verbenas do not succeed when planted in the garden. This is especially so in light soils and dry districts, and even where they do flourish some varieties can never be seen to advantage unless they have the protection of glass—protection of which they are eminently worthy; for what does it amount to?—simply a cold frame, so many of which remain idle during the summer months. I know from much experience how well a few spare lights can be occupied in protecting Verbenas which are grown for producing flowers for cutting. I know how those flowers are valued by those who possess them, and admired and even coveted with a pardonable if not commendable sort of covetousness by others who inspect them. For many years I have grown cut flowers for ladies of taste; and next to Roses, and standing, I think, higher than Pinks and Carnations, Verbenas are the most prized. These Verbenas are grown mostly under glass—grown in pots in spare frames. Most easy is the cultivation of Verbenas in this way, most certain are they in producing a profusion of flowers, and most welcome are they for the ladies' boudoir and drawing-room.

Given stout healthy plants in spring, they only require potting in sound soil in 5 or 6-inch pots, to be kept free from insects, and be duly supplied with water. Insects are easily killed, or, what is better, prevented by fumigation and occasionally syringing with soft-soap water. The plants should be placed on or partially plunged in ashes in a frame facing north, and from which the lights should be removed for some hours every evening, drawing them off when the plants are watered, and leaving them off even all night in fine weather. The quantity of flowers that can be cut from about twenty plants is something surprising—that is, if the plants are well supported. A few plants when not cut from will if neatly trained make beautiful decorative objects. But it is for affording flowers for room decoration that Verbenas in pots are so valuable and recommendable. All who have a demand for cut flowers in summer should grow Verbenas in this certain and easy manner. The flowers, however, are not good travellers, but when cut and placed in water immediately they last quite long enough.

A frame full of healthy plants cannot fail to be found most useful; but if the plants are neglected and insects are allowed to feed on them, or if water is not given freely and the growth becomes hard, then are Verbenas unsightly and disappointing. Grow them well and Verbenas in pots will give a reward. The following excellent varieties I noted as being exhibited at South Kensington:—Annie, Apollo, B. A. Hallam, Black Prince, Celestial Blue, Christine, Crystal Palace, Edwin Day, Firefly, Fairy, Florence, Géant des Batailles, King of Lilacs, Lord Raglan, Magnificens, Nemesis, Prince of Wales, Queen of Whites, Rev. C. P. Peach, Rev. P. M. Smith, Apology, Duke of Edinburgh, The King, Claudiana, Lady of Lorne, and Lady Ann Spiers.—A VISITOR.

### SYRINGING.

REFERRING to this subject, I may state that while going through the houses at Drumlanrig the other day the young man in charge of the plant stove there was closing this place in the afternoon and giving the plants a thorough drenching over-

head with a strong garden engine, and Mr. Thomson remarked to us that that was the best of all the insecticides. As to the condition and appearance of the plants, I have seen specimen plants at the London shows and elsewhere, and new and rare kinds in many localities, but I have never seen such healthy well-grown plants as the stock at Drumlanrig at the present time. I need not mention one kind of plant in particular; from the smallest to the largest, and from the newest to the oldest, without a single exception, every one of them is a first-rate example of high culture. Many of the Palms and Crotons are very large in size, and large quantities of small and middle-sized plants are grown for room decoration in the Castle.—A MIDLAND-COUNTIES READER.

### WACHENDORFIA THYRSIFLORA.

WACHENDORFIAS are bulbous-rooted plants from the Cape of Good Hope, but they are not commonly found in cultivation,

Fig. 7.—*Wachendorfia thyrsiflora*.

possibly because bulbs from Holland are so plentiful and varied and withal so easily cultivated that others more or less obscure are not much sought for. Wachendorfias are, however, both distinct and attractive, and are worthy of being included in the collections of those who appreciate plants of this nature. In general character they are not very dissimilar to some of the Scillas, but in colour they are totally different. In the Scillas the prevailing colour is blue, in the Wachendorfias it is yellow. There are a few exceptions—for instance, *W. hirsuta* is violet, and *W. brevifolia* is purple, but nearly all the species are yellow, including the one now figured, *W. thyrsiflora*. This is a very old species, having been introduced more than a century ago.

The plants are of easy culture, the bulbs only requiring to be

potted in very sandy soil containing about a third of peat, giving the usual after-treatment necessary to plants of this nature—that is, watering sparingly at first, increasing the supply with the growth of the plants, affording them little or no moisture when in a dormant state. They are greenhouse bulbs. The genus was named in honour of E. J. Wachendorf, a Dutch botanist. They are readily increased by seeds or offsets.—K.

### GLORIOSA SUPERBA.

It is quite true as suggested by "W. T. S." on page 45 that this plant is highly worthy of culture. The flowers are truly striking and remarkable, and cannot fail to arrest attention wherever they are seen. They are both quaint and beautiful—quaint in form and beautiful in colour. This is, as your correspondent has stated, a very old plant, and also in a great measure a forgotten plant, and it is now rarely seen in cultivation. The on-looker at the Aquarium who described it as a "Lily of some sort" was not far wrong, for it is allied to the Lily, and has as one of its several synonyms *Lilium zeylanicum superbum*. It is also known as *Methonica superba*, that being the name by which the plant is known in Malabar. It was figured more than half a century ago in the "Botanical Register," and in the first volume of that work its name is referred to as being "more worthy of the whim of a Dutch florist than of the taste of Linnaeus," and where the plant is also well described as follows:—

"The plant is singular as well as beautiful. The scarlet undulate retroverted ascending segments of the corolla are likened by Linnaeus to so many flames. The style points horizontally, and appears as if broken at the base and fallen on its side. The root is a fleshy, brittle, elongated, somewhat flattened tuber, bent downwards on each side from the middle into a kind of arch, from the upper part of the centre of which the stem rises. The stem is from 6 to 10 feet high, weak, and supported by the hold the leaves take of the neighbouring plants by means of a spiral tendril growing from their point. The corolla varies from 2 to 3 inches in depth. Its place in the natural system is among the Lilia, near to *Erythronium* and *Uvularia*. It is a native of the East Indies, and was introduced by Mr. Bentinck, afterwards Lord Portland, in 1690."

Although this plant is generally known by the fanciful name of *Gloriosa*, its true name, says the "Cottage Gardener's Dictionary," is *Clynostylis*, in reference to the way the style bends to one side away from the stamens. In that work the cultivation of the plant is thus concisely given:—

"It is increased by divisions of the roots and seeds; if by the former take a pot that has been kept dry all the winter, say in March, turn it out, and separate the bulbs carefully without bruising them. Place each bulb, with the end farthest from the old tuber, uppermost in the centre of a clean pot, covering it with an inch or two of soil, the pot being 5 or 10 inches, or any intermediate size, in diameter, according to the size of the bulb; peat, loam, leaf mould, old cow dung, and sand in equal proportions, with good drainage. Give no water until the bud appears above ground, then water and place in a strong moist heat, growing vigorously, and training as the plant proceeds. When done flowering, and the leaves turn yellow, refrain from watering, and shortly after turn the plants on their broadsides in a dry place, and allow them to rest until next season."

To that it is only necessary to add that the plants after starting into growth in the hotbed in which the pots have been plunged, will grow freely in an ordinary stove, or even in an intermediate house where light and a moist genial atmosphere is afforded. They grow and flower freely, and where a suitable house is provided there is no difficulty in growing this remarkable plant—or plant with remarkable flowers—satisfactorily. It is to be hoped that these singularly beautiful flowers will not be so rare in the future as they have been in the past, for none are more striking, and they are also easily produced.—F. H. S.

### TAKE-UP THE EARLY POTATOES.

The growth of the early Potatoes, somewhat retarded by the cold inclement weather of spring and early summer, has been brought to maturity with great rapidity by the late hot dry weather. I do not mean by maturity that the haulm is decayed, for with the exception of a tinge of yellowness in the lower leaves it is as green and vigorous-looking as that of

the late sorts, but that the tubers have ceased to grow, and are therefore ready for lifting, which should be done with the greatest possible promptitude and dispatch, because it is precisely at this point that they become susceptible to blight. An abundant crop of Myatt's Prolific Ashleaf and Royal Ashleaf is already in the store-shed in splendid condition without a blemish; other kinds will follow in due course, and judging from present appearances I anticipate having the entire crop lifted and housed by the third week in August.

Let me repeat the warning so often given before—Watch your Potatoes closely during the next two or three weeks, and as soon as you are convinced that the tubers have done growing take them up at once however green the haulm may be, store them in as dry a condition as possible, let the air play freely among them afterwards, turn them occasionally till they are thoroughly dry, and you may laugh at the disease and have no need to trouble your mind about blight-proof sorts—fungi, resting spores, or kindred subjects.

As the crop is taken up carefully select seed for planting next season, laying it out thinly at once upon shelves specially set apart for that purpose. Avoid greening or any other fanciful process; only lift the tubers in a sound condition, and there need be no fear of their not keeping well provided they receive due attention in the store-shed.—EDWARD LUCKHURST.

### FEATHERED HELPS IN GARDENS.

I WAS pleased to see more than one notice of the usefulness in gardens of that sprightly and unique bird the peewit, or plover, or lapwing, for the bird is known by all these names—in the eastern counties by the first name, in the western by the second, and in books on natural history by the third.

Having kept peewits I can speak much in their praise. If I had a walled garden I should have them now; but wall there must be, for this little bird is at the breeding season as determined to escape as is that strange crafty creature the tortoise, which when the time comes round will do its utmost to get away, rearing its ungainly self on its hind legs and trying every fence and bar: so likewise in its own peculiar way will the peewit act.

First I would say do not pinion the little bird; it injures it permanently. Cut the feathers of one wing (don't pluck them, as they would soon grow again); cut them, and that will last a year. Let them have a shallow dish or pan to drink from and bathe in; then, not only in frosty weather, but in very dry summers, when slugs cannot be found and the earth yields no worms as now, feed them. I used to cut raw liver into narrow worm-like pieces, and the birds fed close by me and did well.

Recently I saw a peewit in a walled garden in Hampshire—a very good garden by the way—and he came to us at tea near the summer-house and had breadcrumbs; but the bird did not look in good feather, for worms and animalculæ are their natural food, and failing them raw meat. I know no pet more interesting if it become tame. Just a year ago I caught a young one, recently hatched, on Salisbury Plain close to Stonehenge. What a beautiful little ball of down it was! and though so young the full, large, handsome eye of the plover marked it as no ordinary bird. I petted it, and put it on the ground to the joy of its mother who was almost mobbing my hat, so near did she come from her anxiety for her little one.

I have mentioned the "full eye" of the peewit. The robin is another of the fine-eyed birds. Bloomfield has noticed this in his "Soldier's Return Home," where he says—

"That instant came  
A robin on the threshold; though so tame,  
At first he looked distrustful, almost shy,  
And cast on me his coal-black steadfast eye."

That description of the robin's eye is very happy; but the peewit's eye is fuller and finer, with a softened look, for it seems to swim in liquid light.

I hope all who place peewits in their gardens will be sure to remember that they cannot exist without food being given to them in very dry as well as in frosty weather. Aye, feed them on the first frosty morning. 'Tis a feeble little life, and must be supported. How should we like to starve even one day? Shakspeare, who was a country boy, notices the habits of the lapwing thrice, and in his own charming way—thus, "The lapwing runs away with the shell on his head." He says this of a forward fellow, alluding to the bird's precociousness. Then he had seen the peewit's craft in leading the boy plunderer from its eggs; hence he says, "Far from her nest the

lapwing cries away." And he had noticed also the bird's habit of avoiding being seen by running close to the earth—"Like a lapwing he runs close to the ground." Even Milton blunders in his natural history, Shakespeare never. He who so accurately noted a Cowslip as to write—

"On her breast  
A mole cinque-spotted, like the crimson drops  
F' the bottom of a Cowslip"

(and whoever saw a Cowslip without the five spots?), as accurately marked the habits of the lapwing.—WILTSHIRE RECTOR.

### ROSES AT KENSINGTON.

"WILL you come into my garden?  
Says the spider to the fly."

The clever spider being your Sub-Editor, the poor fly your humble correspondent. I was staging Roses in all the amateur classes, judging the nurserymen, and then was allured into taking notes for you. What wonder that I was, as I was consolingly informed, "too late" for your last issue?

The date of the Roses at South Kensington was not the fresh leafy month of June, but the 19th of July, torrid and thirsty almost as was the *Wyld Savage*, as a dissenter once called your mild correspondent, punning upon the name of my poor benefice, Monkton Wyld, and yet the Show was grand. Let me preface my remarks on the Roses with a growl, it is but a little one, and best to have it over at first. Why will not the Society have more Judges? I was present as your "chief taking notes," but I found that only three Judges, and two of these no one, as far as I could learn, had ever been heard of as rosarians, were told-off to judge Roses, Lilies, Fuchsias, greenhouse plants, *et id omne genus*. So I helped to judge the nurserymen with Mr. Quennell, and retired to a discreet distance when the amateurs were judged. I was ill-used. Everyone but two Judges admitted that my beloved Teas were very close indeed for first, Mr. Quennell being rather doubtful whether I was not first; but at all events I was easy second, and here I was placed a poor third, feeling in the same position as the man did who was assured that, though he was nowhere in Roses, he was easy first in moss.

And now for the profession. The nurserymen staged some very fine stands. Mr. Cant of Colchester was again first, showing that he is at least this year *nulli secundus*—all through the year with the exception of the Alexandra Park, where he had to contend with his great Cheshunt rival, who was almost on the spot. Among Mr. Cant's beautiful Roses were marvellous fresh and good blooms of *La France*, *Maréchal Niel*, and *Emilie Hausburgh*. A grand Rose is this latter for the late shows, hardly a stand was seen without a good bloom of her. He showed also his new seedling *Prince Arthur*. This is a great desideratum, rather like *Général Jacqueminot*, but with more substance, and the colour more after *Duke of Edinburgh*. His Teas, of course, were very fine, notably *La Boule d'Or*, the difficult Rose to bloom. This, however, is just the season for it. I for one had it in every stand, and Captain Christy showed it fine in his twelve, where, by the way, he was first. Mr. Cant also had a bloom of *Princess Beatrice* which astounded me. In fact all Mr. William Paul's novelties have this year been shown remarkably well. *Star of Waltham* is a very great acquisition. *Duchesse de Caylus*, and *François Michelin*, *Marie Rady*, and *Madame Victor Verdier*, and especially that gem of the purest water, *Duchesse de Caylus*, were all grand.

Messrs. Cranston & Mayes were second with a very even stand of blooms, which, though not in anything like their best form, were yet very good for the time of year. *Etienne Levet*, *Reynolds Hole*, *Marie Rady*, and *Emilie Hausburgh* were very fine. Mr. Prince of Oxford came third with his seedling *Briars*, and here, as a proof of the superiority of his stock for Teas, he showed us a *Maréchal Niel* which was undoubtedly the bloom of the Show. The rest of his blooms, with few exceptions, were a little coarse. *Alfred Colomb*, however, he showed splendidly, and also *Marie Baumann* and *Comtesse de Sereniy*, which novelty, by the way, was in many stands, and always good. Mr. Keynes of Salisbury was fourth. He had a bad back row, and was all through overblown. He showed, however, a very fine bloom of the old variety *Black Prince*, which Mr. Cant also had in his twenty-four, very fine.

In Class 2, for twenty-four (amateurs), Mr. Davis of Wilton Park, Salisbury, was first, and I was second. Mr. Davis showed some splendid blooms. In Class 3, twelve distinct (amateurs), Captain Christy was first with a very fine stand, containing a bloom of a Rose which he called *Souvenir de Colommer*, which, if not *Marie Rady*, must be her elder brother. But the complete prize list has been given, so I will not write any more about the prizewinners.

The florist flowers were so beautiful and of such marvellous form, the finished work of such artists, that an outsider like myself could only sigh and wonder. I have finished my work this

year, and have chronicled the last of the metropolitan shows, and enjoyed the finest show that I have ever seen at Kensington.—JOHN B. M. CAMM.

### SIR JOSEPH PAXTON STRAWBERRY.

I HOPE "J. T." and "W." have quite satisfied themselves that they have obtained a true sample of Sir J. Paxton before making such an onslaught upon the merits of one of the most useful Strawberries in cultivation. This at least has been my experience of its value for the past seven years. In flavour it may be a little deficient, but what Strawberry will command a better sale or travel better than Sir J. Paxton?

It may, perhaps, interest "J. T." and "W." to know that in July, 1874, I planted twelve hundred plants, and in July, 1875, I had a fair crop of fruit, and I fearlessly assert there were not twenty unfruitful plants out of the twelve hundred. Of this season's produce I am quite unable to speak, for I left the county in November last.

My very first acquaintance with this valuable Strawberry dates back to the time when the plants were 15s. per hundred. Sterile plants there are to be found in every variety, but I have found but very few in Sir J. Paxton. Some years since I received from a nurseryman plants of *President*, but not ten out of the hundred were fruitful, and what was more annoying to me, these few fruitful plants were not *President*. Three years since I received plants of *President* from a brother gardener; these I know were pure enough, but unfortunately three-fourths proved barren, and thus ended my experience of *President*. Now, the simple cause of so many complaints against the different varieties of Strawberries arises from the fact that all unfruitful plants as a rule produce the greatest numbers and finest plants, and from these are often planted large plantations of Strawberries. The purchaser is well pleased at his fine healthy plants; but, sad disappointment and disgust is in store for him, and all owing to inexperience of those employed to raise the plants, and a libel upon a valuable and choice fruit the result of inexperience.

My advice to "J. T." and "W." is to plant Sir J. Paxton from fruitful parents, 18 inches between the plants and 36 between the rows, on any soil in a good state of cultivation, and I venture to predict a satisfactory result; but poison the ground with rank dung, put in the plants as thick as French Beans, and the result will be a harvest of leaves and no fruit.—D. BROWN, *Middlesborough-on-Tees*.

### VARIETIES OF ORCHIS LATIFOLIA.

THIS is one of the most beautiful of our native Orchids; it has shown a marked liability to diverge into permanent, and in more than one instance into very charming varieties. One of the most noteworthy of these, or we should, perhaps, say the most so of any of them, is the very distinct and striking variety discovered by Dr. Moore some dozen years since in a meadow at the base of the Dublin mountains during a botanical exploration in that district. This is a very vigorous and robust form both as regards stem and foliage, the former together with the scape growing to a height of from 18 inches to 2 feet. The raceme of flowers nearly equals that of the *Madeiran Orchis foliosa*, and has greatly the advantage of it in respect of colour, that of the Irish plant being of an intense rosy purple. Besides its stately form and the richness of its flowers, this variety is further remarkable for its precocity in flowering, for it flowers fully a fortnight earlier than the typical form. For this reason Dr. Moore, by way of distinguishing it, aptly gave it the provisional name of *O. latifolia* var. *præcox*. Another very remarkable trait in the character of our plant is its tendency to seed, the readiness with which the seed germinates, and the precocity of the seedlings in growing into flowering plants. Only three roots were transferred from the original habitat to Glasnevin, and one of them, at all events, found suitable and evidently agreeable quarters in the interesting bit of artificial bog there. Here it soon formed a stout tuft, producing several flower stems, forming during a great portion of the month of June each year quite the feature of the interesting spot in which it luxuriates. Now, not alone in the immediate quarters of the original plant are flowering specimens to be seen, but scores of them elsewhere in the garden, as, for instance, among the pots of alpine, where the seed has germinated spontaneously. What makes this more singular is, that a similar tendency to produce seed is not at all a characteristic of the normal form of the plant.

Three years after the original find, Dr. Moore was again botanising in the same district, and visiting the same meadow again came upon it. In all his explorations, there or elsewhere, he never met with it outside that particular spot. From all this it will be seen that, besides being prized for its beauty, this form possesses considerable botanical interest.

We turn, however, from it for the present to notice another quite novel and very remarkable form of the species, recently discovered by the Hon. Mrs. Barton, Straffan House, Co. Kildare, in a meadow near Glenade, Co. Leitrim, at the base of the Benbulbin range of mountains. The fortunate finder forwarded to Dr. Moore the only specimen removed, and he regards it as being the most beautiful of all our Irish Orchids. The plant was fully 14 inches high, and had a close raceme of flowers covering the rachis for fully 5 inches or more of its length. It bore, as Dr. Moore remarks, more resemblance to the raceme of some of the Indian Orchids, such as *Saccolabium Blumei*, than it does to our ordinary forms. The leaves are short and stout, fully 3 inches wide, and beautifully spotted with purple. Only two plants of this splendid variety were met with by the finder when botanising in that rich district. One of these she removed; the other, with the instinct of the true botanist, she let remain. We sincerely congratulate the Hon. Mrs. Barton on this fortunate find, and quite agree with Dr. Moore's suggestion that in future it be known to botanists as *Orchis latifolia* var. *Bartonsæ*. This fine variety would appear to be, as is unquestionably the precocious county Dublin variety, quite worthy of the care and skill of the horticulturist, should it ever become common enough to get into his hands.

Few are aware of what many of our native Orchids are capable of under cultivation, and none of them we apprehend would be more calculated to make a pleasing return for the care and skill bestowed than these beautiful forms of *O. latifolia*.—(*Irish Farmers' Gazette*.)

#### PLANTS FOR ROCKERY.

Our climate is very cold and rainy, our situation high and exposed, and the winds draw round and between the house and church with such violence as to cut most plants to pieces. I have a rockery close to the house, and the winds, cold, and perhaps soil have made great havoc with many plants. Among those of which every plant has died during the last two winters are *Lithospermum*, several kinds of *Sedum*, *Helianthemum*, all variegated *Arabises* and *Alyssums*, *Hepaticas*, and *Gentianas* (excepting two or three), *Gnaphalium luteum*, *Linum flavum*, *Euonymus variegata*, *Achillea tomentosa*, *Myosotis dissitiflora*, *Aubrietias* of all kinds, and *Helianthemums*. The *Helleborus niger* lives in peat at the top of the rockery, but never flowers; the Rock *Cistus* barely lives. Some of the *Phlox reptans* and *Nelsoni* and *Ericas* have lived and some died. The *Statice coccinea* has in most cases lived, also *Sempervivum globiferum* and *flagelliforme*, but other *Sempervivums* have died.

The following seem to thrive pretty well: *Iberis sempervirens* and *corriesolia*, *Alchemilla alpina*, *Primula farinosa*, *Auriculas*, *Campanula rostrum* and *pumila*, *Saponaria ocyroides*, *Adonis vernalis*, *Aster alpina*, common *Stonecrop*, *Enothera*, *Geranium Wallichianum*, and *Achillea millefolia*, the two last on the north side in heavier moister soil. Being afraid of the rainy climate I perhaps made the top foot of soil too poor and dry with sand in nearly equal proportions to garden soil; but there is a foot or two, and in the upper part 2 or 3 feet, of good soil below this. Perhaps also the rockery is too well drained, being built on a stony mound as the base. Will you advise me whether to enrich the surface with a little more good garden soil and manure during the winter ready for replanting in spring; and also oblige me with a list of twelve to fifteen of the very best and most effective rock plants suitable, which will do well without fail, and make good big clumps in a moderate time? I wish to go in for a few that will be sure to do well under the above circumstances, and cover the rockery with broad sheets of colour during the spring months; also please to mark those which will do best on some steep ledges where the soil is shallow and liable to become very dry. Among those I should like to have, if you think they would do when soil is enriched, are the following: *Woodruff* (*Asperula odorata*), *Musk*, *Aubrietia*, *Gentiana acaulis*, *Cerastium*, *Enothera macrocarpa*, and some kinds of *Myosotis*. For the sake of time and expense I should prefer those which are quickly increased, or can be easily grown from seed this summer. I have two cold frames,

would you therefore advise me for safety to keep all seedlings in them during winter, so as to have the whole stock ready to plant out in spring? I fear if planted in autumn they might be lost during winter from not being well established. I have already sown *Iberis sempervirens*, *Alyssum saxatile*, *Enothera macrocarpa*, *Gentiana acaulis*, *Auriculas*, *Myosotis palustris*, and *Aubrietia purpurea*. Can you tell me why *Lithospermum* and *Aubrietia purpurea* have failed utterly? I thought they were perfectly hardy.—NEMO.

[We think we can be of little service to you, as yours appears a very peculiar case. We should certainly take note of what fails, and avoid them in future, planting such as do best in quantity. The *Helleborus niger* would do better at the base of the rockwork, where it will have greater depth of soil and more moisture, and the same remark applies to *Hepaticas*—they have been dried up. Most of the other plants are too tender for any but sheltered rockwork—warm aspects or sunny exposures. Of those you have sown *Myosotis palustris* requires moisture, and will not succeed, neither will *Woodruff* (*Asperula odorata*), which requires moisture and shade. *Myosotis sylvatica* would be better than *M. palustris*, and *M. dissitiflora* ought to succeed if it can have sufficient moisture. *Lithospermum* requires a warm exposure; and as *Aubrietia grandiflora* has failed, why not try *A. deltoidea*? We should not deepen the soil, but add to it some well-reduced leaf soil. The following, which you may raise from seed, would probably succeed: *Antennaria dioica minor*, *Aquilegias* would succeed at the base, *Arabis alpina*, *Aubrietia græca*, *Dianthus neglectus*, *Erinus alpinus* in full sun. *Gentiana verna* you have; it requires deep moist soil, but well drained. *Linaria alpina*, *Papaver nudicaule*, *Saxifraga aizoon minor*, *S. cymbalaria*, and dwarf *Wallflowers*. Most *Saxifragas*, *Sedums*, and *Sempervivums* would succeed, also *Erica carnea*, *Achillea ægyptica*, *A. umbellata*, *Campanula garganica*, *Draba aizoides*, *Iberis gibraltarica vera*, and *Viola cucullata*. The seedlings would be the better wintered in frames with plenty of air in all mild weather. We advise you to first make trial, and plant extensively such as succeed.—Eds.]

#### NEW BOOK.

*Rain and Rivers.* By Colonel GEORGE GREENWOOD, pp. 247, 8vo, Third Edition, 1876. Longman & Co.

A work that has attained to a third edition needs little evidence that it is of considerable interest to the cultivator of the soil and the geologist. It is indeed full of the results of the valuable observations of the author, written in a very healthy joyous spirit; and if the reader does not concur in all the conclusions to which he arrives, he will yet travel with him very pleasantly in his excursions in search of evidence to support his theory of the very extensive action of water upon the surface of our earth.

In describing the origin of our soils, he tells us that "soil is simply rotten subsoil, mixed with vegetable remains; but there are particular spaces so steep (precipices) that even gravity or wind, independent of the wash of rain, would never suffer a grain of soil to remain on them for an instant. Soil is not the less in perpetual formation on these places. The faces of precipices and bare rocks rot, and thus soil is in perpetual formation over the whole surface of the earth; and from the whole surface of the earth it is in perpetual movement by the wash of rain to the bottom of the sea. This travelling rotten part of the earth is the only part which supports vegetable existence, and consequently animal existence."

The Colonel had evidently considered that when God created the earth He made its surface either uneven or level. If it was level, then there could not be any drainage from it. Its soil would be a swamp, tenanted by only a valueless class of plants. There could not be either streamlets or rivers, and had not the Almighty ordained that "the dry land should appear," there would not have been any sea at a lower level of the earth for the rain water which fell upon it to drain into. It was, therefore, when treating of the all-powerful action of rain water in washing away the surface of the earth to form channels for streams, and thus to deposit the mechanically suspended matters, so as to form soils at the bottom of valleys and deltas at the mouth of streams, that the author of this valuable work remarks that "most people are doggedly possessed with the idea that water will not flow on land which has no slope. But as rain falls from high heaven, its only relief from rising on itself is to flow. Empty a decanter of water on the middle of

the table. Does the water remain in the middle? Introduce a pipe of running water to the middle of a flat stone hall. The water flows all over the flat pavement, and finally escapes from the hall by every door. Why? Not because it flows without a fall, but because it rises on itself, and so makes a fall. . . . Stop the pipe of supply, and the hall will run dry; continue the supply for ever, and a channel would be worn at each door. . . . Nature drains and denudes every flat on earth on this principle, a channel being cut backward from wherever the water can escape with a celerity directly as the softness of the soil. These channels become small valleys, and so the flat, no flat, but hill and dale."

If there is a good deal of geological detail in "Rain and Rivers," the reader will find that the geological lore is given in a very amusing style, and he will not fail to follow the author with pleasure in his travels, not only along the seashore, but amongst the water-worn terraces of our own valleys, and of those of far distant lands.

### ROYAL HORTICULTURAL SOCIETY.

THE Council of the Royal Horticultural Society have summoned a meeting of the debenture-holders for Tuesday next the 1st of August, and also one for the Fellows of the Society for Wednesday the 2nd, in both cases to lay before them the present financial position of the Society. To the debenture-holders such a meeting is full of interest. They advanced the money wherewith to enable the Society to make the garden at South Kensington, and they have a substantial interest in the locality. With the Fellows it is different; their interest is of a less material description, and extends only so far as the gratification of their pleasures or pursuits are concerned.

It is known to those who have watched the progress of the Society since the formation of its partnership with the Royal Commissioners for the International Exhibition of 1851, that under the agreements between the two contracting parties which are virtually incorporated in the charter the Royal Horticultural Society was to raise £50,000 on debentures, which sum was to be expended on the Commissioners' property in making an ornamental garden at South Kensington, the Commissioners expending the same amount in enclosing it with arcades. Both these contracts were carried out, but instead of being enabled to do the necessary work for £50,000, the Royal Horticultural Society spent no less than £73,000 before they could complete the work that they had undertaken to do. The Royal Horticultural Society have therefore during the last fifteen years expended £73,000 on the Commissioners' estate, and paid in round figures £30,000 interest on debentures to adorn and maintain those 23 acres of ground at South Kensington.

Practical men of business habits and knowledge of the world will perhaps reproach the Society for entering into such a speculation, and blame those who induced it to leave its quiet retreat at Chiswick and migrate to the glare of the more aristocratic "court suburb." Those who do so must bear in mind of whom the Council was constituted in those days, and by whose advice that bold but disastrous step was taken. He whom our beloved Sovereign and the whole nation mourned, and still mourn the loss of, was President of the Society at the time, and he was unwearied in the attention he gave to a scheme which he believed was for the advancement of science and art, and calculated to be a lasting benefit to the Horticultural Society, which he had taken under his beneficent protection. But a cruel fate arrested his useful career, and from the day that he was laid in St. George's Chapel at Windsor the doom of the Royal Horticultural Society was sealed, and the wise counsellor who devised, and under whom this great design was to have been executed, was removed from his sphere of usefulness.

If the Prince Consort had been spared the Society and other interests at South Kensington would not have been in the state they now are, and it is therefore out of place to cast any reflections on the Society or its Councils because of what happened fifteen years ago, and of the failures it has been subjected to since. The only fault that can be charged against past Councils is that they should have paid interest on the debenture bonds when a profit had not been made. The interest on these is payable out of the surplus receipts from the gardens, and as it is well known that there has not been, except in two or three years, any surplus receipts from the gardens, the payment of debenture interest was manifestly most culpable. This has, no doubt, been the reason why the Society has been so crippled all along. An annual payment of £1950

for interest alone which was not due would ruin any concern. Happily the present Council have acted more justly towards the Society, and the payment of the interest is stopped. It is for that reason that the Council have summoned a meeting of the debenture-holders, and to explain to them the dangerous position of their security in consequence of the inability of the Council to maintain the Society as a going concern at South Kensington.

It seems hard upon the debenture-holders that £50,000 of their money which they advanced in the joint adventure of the Royal Commissioners and the Society should be entirely sacrificed, and that the Royal Commissioners, who are the only persons benefited by this unfortunate speculation, should not do something to alleviate the condition of those who advanced their money, as they believed, on the joint security of the Commissioners and the Society. It is to be hoped that they will regard the question as one of tenant right as well as of partnership, and that they will not suffer any injustice to be done to anyone by assuming what they may suppose to be a legal position. A distinguished body like the Royal Commissioners, incorporated as they were for the advancement of science and art, will, it is to be hoped, execute their trust better than to have it laid to their charge that the only one of the chartered societies that they took in hand became a failure under their fostering care.

### PEACH BLISTER.

HAVING read the description of Peach blister by Mr. Luckhurst and also by Mr. Smith, I am induced to ask a few questions to help us to guard against or to cure the scourge.

I may ask first if Mr. Smith means the form of blister figured at page 31, July 8th, 1875, of the Journal. If so, that does not show the blister we are so subject to here in Sussex. We do not care for that kind of red warts, which are found both inside and out, but to no extent—they do us very little harm; and I do not think we are so simple as to confuse blister with what is commonly called curl, and shows great neglect, for that we can cure or prevent in a few hours with a solution of quassia chips, soft soap, and sulphur. It is that pest that ruins our trees, and of which we know of no remedy but glass houses or cases. Canvas will not do it. My trees are thoroughly protected with canvas, and I have suffered this year greatly. The sap being retarded we have found, instead of leaves and branches, large ugly masses of thick blistered leaves as thick as one's finger. Why do we have this most when the extreme of temperature is the greatest? If it is not the cold winds how is it we do not have it, or very little of it, in a mild spring? Why does it not come later in the season or in the autumn? We never find it then.

It is a fact that it is the worst when the trees are the most exposed to cold; it is a fact that if not exposed to cold winds we do not have it; it is also a fact that the two extremes of temperature are the worst—very hot sun in the day and extreme cold at night. I have a wall well sheltered from the east by Poplar trees, and after eleven o'clock no sun reaches the wall. On that wall I have young Peach trees, and this year they escaped better than those on a south wall. I consider that the extremes of heat and cold were not so great on the east as on the south wall.—S. JENES, *Brambletye*.

### NOTES OF A SCOTTISH TOUR.—No. 1.

NEWTON STEWART.

HORTICULTURAL of course? Yes. I have perhaps as keen an eye for scenery as most people, can rejoice in beholding Nature in all her works, but I have no capacity for describing my feelings in the enjoyment of wood, and lake, and mountain; and although in the short visit I have lately paid to the land o' cakes I have seen much that has given me real enjoyment, and the memory of which will serve as a feast for many a day, yet I had rather tell of that which more concerns the readers of "our Journal." I put on my horticultural glasses, and through them come the impressions which I now record and, I believe, will interest our friends.

I have already given a report of the Rose Show held at Newton Stewart, and told of the zeal and energy with which it is carried out, and so perhaps some would like to know what sort of a place this is with its 2500 inhabitants which can take at a Rose show as much as Maidstone with its 30,000 inhabitants. Well, it is a well-to-do Scottish town where no very great amount of manufacturing interest is to be noted, the

curing of bacon and sawing of wood being apparently its chief occupations; but it is most beautifully situated. The river Cree flows by the town, and on the hills around it are to be noted some very pretty residences, while in the distance glorious mountains with their ever-varying play of light and shade are to be seen. Like many places in Scotland it has its fair share of rain—somewhere about 49 inches, but owing to its vicinity to the west coast the climate is mild, snow seldom remaining for long on the ground. The soil is fairly good, and in sheltered places the Rose does well. The largest place is that of

PENNINGHAME, the seat of Stopford Blair, Esq., who with the Earl of Galloway owns the greatest part of the property in the neighbourhood. It is situated about two miles from the town on the banks of the river Cree, and amidst a most beautiful variety of scenery, from the wild woodland with its natural tarns where the wild duck and teal breed and the Water Lilies grow abundantly, to the cultivated pleasure ground and garden where all is neat and well ordered. One can wander through the woods for hours and enjoy the sights that everywhere meet the eye; while in the garden, under the able management of Mr. Duthie, there is much that is noteworthy. It is not a large garden; indeed in comparison with many I have lately seen it may be called small, but within it are to be found all the useful and ornamental belongings of a well-ordered and carefully tended place. The stoves and greenhouses had a choice selection of good plants; the vegetables were examples of good cultivation, and out-of-door flowers were in good order. An exception must be made to the Roses, which were curiously affected and in a manner I have never seen before. Every tree, whether H.P. or Tea, new or old variety, had all the leaves most singularly curled—in fact doubled over, and this no matter what the position of the plant. Nor is it this year alone, but every year it is the same. I imagine that it is somewhat the same as that which occurs on wall trees—not the blister, but the curl—and occasioned by the same cause, the cold east winds of the earlier spring months. I am the more confirmed in this opinion from noticing that in several instances the trees had already begun to push away, and Mr. Duthie informed me that the second growth was entirely free from it. Just as I was in despair at the aspect of my few wall trees when I saw how they were blistered and curled, but in a few weeks they broke away, and now are getting up to the top of the wall. The only thing that militates in my mind against this is, that no matter where the plants are, it is the same; and one would imagine that, in some places at any rate, they would be sheltered from the blast.

I saw here, and indeed everywhere throughout this part of Scotland, growing in the most wild luxuriance a plant which I have never seen in the south—*Tropæolum speciosum*, and yet I have seen a good many gardens. As many of your readers may be as unacquainted with it as I was, let me say that it is like its congeners a creeper, running about as luxuriantly as the annual yellow one *T. canariense*, with which everybody is acquainted; but this is a brilliant scarlet, most profuse in flowering, and most showy, so that in going into a garden where it is you cannot help exclaiming, What is that? Mr. Duthie told me that it makes very little way the first year it is planted, that it is impatient of pot culture and requires to be well established, but that the second year it becomes a perfect weed and forms very large roots. One border he pointed out to me and said, That is full of them. Can any of our southern friends give any clue to the reason why we never see this plant? Is it that it requires the damper climate of Scotland, or are our winters too severe? It is a native of South America, but where I do not know. Probably with us it would require to be covered over with some protecting material during the winter months; at any rate it is well worth trying, and I mean to do so this autumn.

The evergreens here, as elsewhere through this part of Scotland, remind me of Ireland, so vigorous and flourishing are they, especially the Rhododendrons, and in spring the grounds must be very gay with their many-coloured blooms.

THE RESIDENCE OF MRS. VAN AGNEW is one of the suburban retreats round Newton Stewart, and is one of those old-fashioned places where one expects to find things not met with elsewhere, and thus to see large standards of such Roses as Duchess of Sutherland, Sir Joseph Paxton, and others (the heroes and heroines of past days) was quite in accordance with one's expectations. The house stands high, and commands a fine view of the beautiful scenery of the neighbourhood; and the Rose garden at the side of the house contained most of the varieties which are now grown, while many of the climbing

Roses were making their way over the front of the house. On the opposite side of the river is a pretty residence, rented for the shooting by Mr. Macorquodale, but save the luxuriance of the shrubs there was nothing very remarkable about it. I wish some of those Rose-growers who in our southern climate complain of situation as unfavourable to the growth of their favourite flowers could see the garden at

ALL SAINTS' PARSONAGE.—Imagine a garden without one atom of shelter, exposed to every wind (and the winds here are something worthy of the name), when after a night's breeze you have to walk round your garden and see how many branches of *Calceolarias* have gone, how many Rose buds twisted off or branches broken, and it will be seen that Mr. Mackenzie must have something of the love of gardening, and of the Rose in particular, to enable him to face the difficulties of his position, and yet he does so. He has coaxed Roses somehow to grow; and although in one place where the wind swept over the wall and played sad havoc he has been driven from the field, yet it is only to transfer them to another site, where he hopes to be more fortunate. Had there been but a small belt of trees at the back of his garden, or had it been placed a little lower down, it might have been well; but it is hard work to get them to do, exposed to such blasts as they experience here. I saw here the *Tropæolum* above-mentioned growing well, and also some other herbaceous plants, such as *Aquilegia cærulea*, *Alpine Anuriculas*, *Violas*, *Pansies*. Indeed all this country side seems to suit the latter flowers remarkably well, the cool moist climate being so very different to the heat and dryness of the south, which have almost driven the Pansy out of cultivation. I have already mentioned the success of the Rose show, so much due to him. I may add as a sample of how they do things at Newton Stewart, that on the same day a bazaar held in a small room in the town produced £260 for the Zenana Mission.—D., Deal.

### LEEK ROSE SHOW.

"WILL you judge for us at our Rose Show?" was the question put me by the energetic Secretary of the Leek Rose Society, and indeed a very weighty one it was to answer.

Leek in Staffordshire, and my nearest railway station in Devon! But so kind and pressing and liberal was the Secretary that I could not refuse, and so set off from London on Monday last. I went first to Lichfield, for Leek is somewhat of an inaccessible place, and frequent are the changes you have to make, and very slow the trains after you leave the Midland and North-Western systems. At Lichfield I was just in time for the service at the glorious cathedral, and I do not know which to admire most—the building or the way in which the service was performed, the masterly way in particular that the organist accompanied. I then dined, and dined well too, at the Swan, and I would advise any of your readers who wish to visit one of the most beautiful cathedrals in England to take up their quarters for a day or so at the Swan at Lichfield. They will be waited upon by a charming, fresh, lively, pleasant maid, who, from the moment you arrive, takes you under her wing, and sees that you are as comfortable as at home. It was quite refreshing after a long journey to see her flitting about the room on that hot July afternoon; and I felt much inclined to tarry there, but I thought it wisest to push on to the far end. At Leek I was met by a deputation, who informed me that I was invited and expected to stay at the house of one of the leading men of the town, and that a cab was waiting to convey me there. I was hospitably entertained, and feel very grateful for the kindness which I met with from first to last.

The Show itself was really a very fair one. One open class for seventy-two varieties was the only one offered to nurserymen, the first prize being £8. This brought three exhibitors—Messrs. Cranston & Mayos, Mr. Davison of Hereford, and Messrs. Frettingham of Beeston near Nottingham. Messrs. Cranston and Mayos staged a very fair stand, not by any means one in their best form, but still a good even lot of blooms. They were first. Mr. Davison was second with blooms inferior indeed to Mr. Cranston's, but remarkably fresh and clean, considering the time they had been cut. Mr. Frettingham, for whose benefit the judging was postponed for two hours in order that he might cut that morning, was left hopelessly behind. His blooms were coarse rough specimens, and nearly all too much expanded. He was third because there was no other to compete with him. But instead of being grateful, he was quite the contrary; or we might say, as in logic, "contradictory."

The rest of the Show was composed of exhibits of Roses, Pansies, table decorations, bouquets, and stove and greenhouse plants, and these were all shown by men resident within six miles of Leek. The exhibitors were few, the most part working men, and I do not think anything could be more gratifying than to see the blooms they showed. I am afraid there would be

many heartaches that night, for the numbers of entries were so large that many must have been left out in the cold. One exhibitor was disqualified by the Committee because he would not admit the Inspector into his garden. His blooms were very good, and it is much to be lamented that he brought this upon himself. It is the custom of the Society, in order to prevent as far as they can unfair practices, to send their Inspector to visit the gardens of those who enter for the Show, so that he may see whether there are any Roses likely to be shown on the day. This plan is, I believe, adopted at Nottingham and other places, and works very well. Many of the amateurs' stands were very good, but they nearly all lost points from the bad way in which they set-up their blooms. None of them cut them long enough; you could scarcely see any wood if you lifted a bloom out of the tube. Duplicates, too, were not uncommon, and I never saw so many Roses misnamed. But as the productions of working men they were the best I have ever seen; the cottagers' blooms at Hereford were not to be compared with them, and the numbers of stands at Leek were larger than at any other country show of the kind which I have visited.

I am afraid, however, that the Exhibition was not a financial success. At four o'clock when I left there were not twenty people in the room, and last year they only took £3 at the doors. Rose shows are not supported in the way they ought to be, and I am afraid that the Leek Show will entail a loss on the Society, like it, appears, the grand Show at Maidstone has done. It will be a great pity if this is the case, as a Society like this does much good. It encourages working men to stay at home in the spring and summer evenings to work in their gardens and cultivate the queen of flowers. Nothing is more civilising, more humanising than flowers. We may say of the Rose that it *emollit mores, neque eos sinit esse feros*, although my friend from Nottingham proved the exception to the rule. I saw none of "the cloth" there, and wonder how it is that no clergyman in those parts loves the Rose well enough to take the trouble to exhibit it. But it was a most enjoyable Show, and you will oblige me and the Committee (at whose request I write these lines) if you will find space in "The Rose Journal" for this account.—JOHN B. M. CAMM.

## EARLY WRITERS ON ENGLISH GARDENING.

No. 16.

PHILIP MILLER AND THOMAS MARTYN.

DR. PULINNEY says truly that Miller raised himself to a degree of eminence rarely, if ever before, equalled in the character of a gardener. The eminence was thoroughly deserved, for not only was he a highly skilled horticulturist, but a good botanist, the author of the best work on plants and their culture, and, as Switzer his contemporary testifies, a man characterised by "generosity, openness, and freedom." Yet of this "Prince of Gardeners," as he was termed by foreigners, no authentic portrait is known. To the French edition of his great work published at Paris in 1785, entitled "Dictionnaire des Jardiniers de Philippe Miller," there is prefixed what Professor Martyn terms "a fancy portrait of the author in a bag-wig and ruffles, a costume which must appear truly ridiculous to such as remember the plain old-fashioned English dress in which Mr. Miller always appeared." This fancy portrait I have not seen, and I have been able to add little to the following biographical details.

He was born in 1691. His father was gardener at Chelsea to the Company of Apothecaries, in which place his son succeeded him in 1722. To the knowledge of the theory and practice of gardening he added that of the structure and characters of plants, and was early and practically versed in the methods of Ray and Tournefort. Habituated to the use of these from his youth, it was not without reluctance that he embraced the system of Linnæus, but was persuaded at length by the arguments of Sir William Watson and Mr. Hudson. To his superior skill the curious owe the culture and preservation of many fine plants which in less able hands would have failed at that time to adorn the conservatories of England. His attention was not confined to exotics: few have been ever more acquainted with our indigenous plants, the most rare species of which he cultivated with success. Miller had some remembrance of Ray, and spoke with evident delight of having seen that venerable botanist. He was admitted not only a Fellow of the Royal Society of England, but also a member of the Botanical Society at Florence; he had an extensive correspondence in foreign countries, and was sometimes by foreigners styled *Hortulanorum Princeps*. Of his Dictionary Linnæus has said, "Non erit Lexicon Hortulanorum, sed Botanicorum." A short time before his decease Miller was induced by increasing infirmities to resign his place at Chelsea, and died December 18, 1771, in the 80th year of his age.

The works of Miller are rather important than numerous. He published without his name "A Catalogue of Trees, Shrubs, and Flowers which are hardy enough to bear the cold of our climate in the open air, and are propagated in the gardens near London," in 1730, folio, with twenty-one plates. "Catalogus Plantarum Officialium quæ in Horto Botanico Chelensi aluntur," 8vo, 1730. Of "The Gardener's and Florist's Dictionary, or a Complete System of Horticulture, by Philip Miller, Gardener of the Botanic Garden at Chelsea," the first edition was published in 1724 in two octavo volumes. The second edition in folio appeared in 1731, and is usually called the first; third edition, 1733; fourth, 1737; fifth, 1743; an additional volume, 1739; sixth, 1748; seventh, 1752; eighth, 1759; published in numbers, ninth, 1768—"plants cultivated in 1768 more than double those known in 1731;" and the tenth, edited by Professor Martyn, in 1807. Smaller editions were published to thwart pirates, the sixth edition of which appeared in 1771, the last year of Miller's life. In the same or the ensuing year he published "The Gardener's Kalender" in 8vo, which has run through a vast number of editions. To one, which appeared in 1761, the author prefixed "A Short Introduction to the Knowledge of the Science of Botany," in which he explains the Linnæan terms, and illustrates the characters of the classes in five plates. This introduction was also sold separately. He began in 1755 to publish his "Figures of Plants," adapted to his Dictionary, which proceeded in numbers till it amounted to two volumes in folio, containing three hundred plates. His extensive correspondence with botanists and others in various parts of the globe enabled him to execute a work of this kind in a superior manner. From the Cape of Good Hope, from Siberia, from North America, and particularly from the West Indies by means of Dr. Wm. Houston, he received for a long series of years a plentiful supply of rare, and frequently of new species, which his successful culture seldom failed to preserve. His original design was no less than to give one or more species of all the genera; but this was found impracticable, and the work was therefore confined to such plants as he esteemed the most beautiful, useful, or uncommon. "The Method of Cultivating Madder as it is practised by the Dutch in Zealand," 4to, 1758. Besides these publications he wrote several valuable papers in the "Philosophical Transactions," one of which was "An Account of bulbous roots flowering in bottles filled with water," a result then lately discovered.

Milleria was named in his honour by Professor Martyn in his "Decades Plantarum Rariarum."

The best edition of his dictionary was edited by the Rev. Thomas Martyn, Professor of Botany at Cambridge, and he deserves in these pages a more than brief notice. He was the eldest of the three sons of John Martyn, M.D., also Professor of Botany at Cambridge and a physician resident at Chelsea. After taking at Cambridge the degree of B.A. in 1756 he removed to Sidney Sussex College and was elected a Fellow. He proceeded M.A. in 1759; in 1761 his father, after having most ably filled the botanical chair for thirty years, resigned it, and the son was chosen to succeed him; and on the election of Dr. Elliston to the Mastership he was appointed one of the tutors of the College. In both offices he exerted his talents with assiduity; as Professor he read lectures in English instead of Latin, and subsequently voluntarily extended his duties to the illustration of the animal and mineral kingdoms as far as they are connected with botany.

In 1763 he published his first works, "Plantæ Cantabrigienses, or a Catalogue of the Plants which Grow Wild in the County of Cambridge, disposed according to the System of Linnæus; Herbariones Cantabrigienses, or Directions to the Places where they may be found, comprehended in Three Botanical Excursions, to which are added Lists of the more Rare Plants Growing in many Parts of England and Wales," 8vo; and "A Short Account of the Donation of a Botanic Garden to the University by Dr. Walker, Vice-Master of Trinity College, with Rules and Orders for the Government of it," 4to. In 1764 he served proctor for the University, and in 1766 he proceeded B.D. In the latter year he published "The English Connoisseur," 2 vols., 12mo, and in 1768 a sermon for the benefit of Addenbrooke's Hospital. In the same year he lost his father, and the two following were spent on a work which should perpetuate that father's memory. This was editing the Doctor's learned "Dissertations and Critical Remarks on the Æneids of Virgil, containing among other interesting particulars a full Vindication of the Poet from the Charge of an Anachronism with regard to the foundation of Carthage." To this work,

which was published in 12mo, 1770, he prefixed a life of the author and a complete catalogue of his works, accompanied by notices of other branches of his family and numerous literary characters as specified in "Nichols's Literary Anecdotes," vol. iii., p. 157. In 1771 he issued a "Catalogus Horti Cantabrigiensis," 8vo, and in following year a second edition, accompanied by his botanical lectures and a plan of the garden.

In 1771 he was presented to the rectory of Ludgershall, Bucks, a living in the patronage of his own family, which he retained till 1785, and soon after he married Miss Elliston, sister to his friend the Master of Sidney, and aunt to the Manager of Drury Lane Theatre.

In 1773 appeared in 4to "The Antiquities of Herculaneum, Translated from the Italian by Thomas Martyn and John

Fig. 8.—REV. THOMAS MARTYN.

Lettice, Bachelors of Divinity and Fellows of Sidney College, Cambridge. Vol. i., containing the Pictures." Mr. Martyn's next work was "Elements of Natural History," 1775, 8vo. On the 23rd December, 1776, he was preferred to the vicarage of Little Marlow, Bucks, by his pupil, Admiral Sir John Borlase Warren, Bart. At this, or probably an earlier period, Mr. Martyn resided at Triplow near Cambridge, engaged as private tutor to four or five young men of fortune. On August 6th, 1777, the Rev. Mr. Tyson wrote to Mr. Gough:—"Martyn is about a Flora Cantabrigiensis, to be published next spring. I have the sheets to make additions to and to correct."—(*Nichols's Lit. Anecd.*, viii., 628.) Whether this work was actually pub-

lished, or the materials incorporated in another work, does not appear. In 1785 he published in 8vo a translation of Rousseau's "Letters on the Elements of Botany," accompanied by additional letters; a second addition appeared in 1787. In the latter year he was presented by the Earl of Coventry to the perpetual curacy of Edgware, which he retained till his death. In 1778 he edited "Thirty-eight Plates, drawn and engraved by F. Nodder, Botanical Painter to his Majesty, with Explanations to Illustrate the Linnæan System of Vegetables, and particularly adapted to the Letters on the Elements of Botany," 8vo. The Professor occasionally attended on Queen Charlotte in the gardens at Kew.

About this time Mr. Martyn accompanied through France, Switzerland, and Italy Mr. Hartopp Wigley of Dalby Hall, Leicestershire, who was another of his pupils. These travels produced from the Professor three publications:—"A Sketch of a Tour through Switzerland, &c.," 1787, 8vo; a new edition (the ninth) of "The Gentleman's Guide in his Tour through France, &c.," 1787, 8vo; and a most useful "Tour through Italy," 1791, 8vo.

After his return Mr. Martyn resided about three years on his living at Little Marlow, and during that time issued his "Flora Rustica," two vols., 1792-4, and first published his "Language of Botany, being a Dictionary of the Terms made use of in that Science principally by Linnæus, with Familiar Explanations, and an Attempt to Establish Significant English Terms," 1793, 8vo. A "Description of *Hæmanthus multiflorus*, with an Engraving," appeared as a separate 8vo pamphlet. From Little Marlow the Professor removed to London on accepting the honorary office of Secretary to the Society for the Improvement of Naval Architecture.

But Mr. Martyn's grand labour was the edition of "Miller's Gardener's and Botanist's Dictionary," in four vols., folio, 1803-7, dedicated to Sir Joseph Banks. To this he for the first time added "A Complete Enumeration and Description of all Plants hitherto known, with their Generic and Specific Characters, Places of Growth, Times of Flowering, and Uses both Medicinal and Economical; with the Addition of all the Modern Improvements in Landscape Gardening, and in the Culture of Trees, Plants, and Fruits, particularly in the various kinds of Hothouses and Forcing Frames." His plan for this work he had communicated to the "Gentleman's Magazine" as long before as 1788.

In 1818 he removed to Portenhall, the place of his decease, being presented to that rectory (a family living) by the Rev. John King Martyn. He died in June, 1825.

As a preacher of the Gospel of Christ, which he adorned by his life and doctrines, he was distinguished by strong sense, accurate knowledge of human nature, and comprehensive scriptural learning. Candid, courteous, and affable, he conciliated the friendship and esteem of many eminent men of all parties. Practical benevolence and charity were conspicuous traits in his character, and the exercise of them was confined neither to place nor party.

### ORCHID CULTURE.

THE increase in the culture of this class of plants throughout Europe and America within the last few years, and the great perfection which is attained in the cultivation of such kinds that used to be considered almost impossible to manage, is really astonishing. The high, moist, and almost unbearable temperature which used to be thought indispensable in the successful culture of Orchids has been mostly abandoned, and a more airy and natural temperature adopted and with marked success. The plants are healthier, flower more abundantly, and are kept more free of insects than when the extreme high-temperature system was employed. The great rage throughout England just now appears to be for what are called "cool Orchids," which comprise some of the finest treasures in the floral world, such as some of the species of *Cattleya*, *Odontoglossum*, *Masdevallia*, *Disa*, *Barkeria*, *Lycaste*, and many others which can be grown in any house when a cool, steady, moist temperature can be maintained free from cold draughts of air passing through amongst the plants. The numerous varieties of *Odontoglossum Pescatorei*, *O. Alexandræ*, and *O. grande*, give them an attraction, making them worthy of a house specially devoted to their culture. The *Odontoglossum* house being a specialty about a good many places in England and Scotland. Of course it is not to be supposed when a cool temperature is mentioned that a cold temperature is meant, and that a general collection of Orchids will with impunity bear a low temperature for any lengthened time is erroneous; from such treatment such plants as *Phalænopsis*, *Saccolabiums*, a good many of the *Vandas*, and other genera from the East Indies may look for a short time in a healthy condition, but spot is eventually sure to make its appearance, and if once this worst of all Orchid diseases gets a commencement in a collection of Orchids it is difficult to stop, and can scarcely be cured. The most devastating case I ever witnessed of this disease was in a valuable collection of Orchids in the north of Scotland. The plants had been growing vigorously for several years, when a change of gardener, who was a strong advocate of the cool-treatment system, changed the tempera-

ture, keeping it too cold for the welfare of the plants, the result being spot of the most malignant kind upon *Phalænopsis*, *Vandas*, *Ærides*, and *Saccolabiums*, completely destroying this once beautiful collection. I visited a collection of Orchids a short time ago in this country, composed of East Indian and Mexican Orchids which have been kept for some time back very cool, and although previously in excellent health I could observe upon some of those which are natives of very warm countries strong indications of spot making its appearance, while such kinds as are natives of Mexico and other parts of Central America are in excellent condition, fully substantiating what experience has always taught me, that while Orchids from the highlands of Central America do best and keep in the healthiest condition when grown in a cool steady temperature when sufficient air is admitted to prevent a stagnant atmosphere, such plants as are natives of Moulmein and other parts of Burmah require a much warmer temperature at all seasons, especially when making their growths.

One of the most fatal mistakes in growing cool-house Orchids is keeping them too dry at all times, which is just the opposite of what they should be, more especially in this country where evaporation is so rapid.

Mr. Rand, in his excellent work on Orchid culture, says, "Orchids must have a house for themselves." This I do not altogether agree with, as the fine specimen plants I saw of some of the most difficult kinds in cultivation at some of the places I visited during my stay in England this winter, which were growing in houses mostly devoted to the culture of other plants, testify that they can be grown, and with success associated with other plants. Where there is a large collection of Orchids, or of any particular class of plants, it is unquestionably the better way to devote a place for themselves; but no collection of plants in the country, whether greenhouse or hothouse, can be considered complete without a few Orchids in it. Some of the finest Orchids we have are of much easier culture than plenty of the hothouse and greenhouse flowering plants.

I have seen some excellent specimens of ornamental-leaved plants and good plants of Orchids in fine flower exhibited at the different horticultural exhibitions in Boston, but very seldom have I seen a good specimen of *Stephanotis*, *Ixora*, *Franciscæa*, or *Dipladenia* exhibited. Horticulturists are not needing, therefore, to be deterred from having in their collections a few Orchids because they cannot set aside a house for their particular culture. Bestow the same care upon Orchids which other plants require with which they can be associated, and they will amply repay the trouble.

The following is a list of a few kinds suitable for culture in the greenhouse:—*Dendrobium nobile*, *Cattleya citrina*, *C. Mossiæ*, *Cælogyne cristata*, *Cypripedium barbatum*, *C. venustum*, *C. insignis*, *Lycaste Skinnerii*, *Odontoglossum grande*, *O. Alexandræ*, *Phajus grandifolius*, *P. Wallichii*, *Zygopetalum Mackayi*, &c.—M. MILTON.—(*American Gardeners' Monthly*.)

### THE ROYAL GARDENS AT KEW DURING 1875.

(EXTRACTS FROM DR. HOOKER'S REPORT.)

THE lessons given to young gardeners in the evening in chemistry, meteorology, structural and economic botany, and upon which the attendance is voluntary, continue to give satisfactory results.

The following plants of especial botanical interest, amongst others of less importance, have flowered during the past year in the Royal Gardens for the first time in this country.

*Albuccia glandulosa*, *Bak.* *Androsace sarmentosa*, *Wall.*—(*Bot. Mag.* 6210.) *Anthurium Saundersi*, *Hk. f.*—(*Bot. Mag.* 6218.) *Carica candamarcensis*, *Hk. f.*—(*Bot. Mag.* 6198.) Flowered, 1874, fruit ripened, 1875. *Colchicum luteum*, *Bak.*—(*Bot. Mag.* 6153.) *Columella oblonga*, *R. & P.*—(*Bot. Mag.* 6183.) *Crassula Bolasii*, *Hk. f.*—(*Bot. Mag.* 6194.) *Cucumis sativus* var. *sikkimensis*, *Hk. f.*—(*Bot. Mag.* 6206.) *Decabellone Barklyi*, *Dyer.*—(*Bot. Mag.* 6203.) *Diets Huttoni*, *Hk. f.*—(*Bot. Mag.* 6174.) *Dipadi hydricum*, *Bak.* *Diuris alba*, *Br.*—(*Bot. Mag.* 6201.) *Draba hederifolia*, *Coss.* *Eranthemum hypocrateriforme*, *Br.* *Ferula (Euryangium) Sambul*, *Hk. f.*—(*Bot. Mag.* 6196.) *Heteranthera limosa*, *Vahl.*—(*Bot. Mag.* 6192.) *Hoodia Gordoni*, *Sweet.* *Hypoxis pannosa*, *Bak.* *Lewisia brachycalyx*, *Eng.* *Milla Leitchii*, *Bak.* *Michelia lanuginosa*, *Wall.*—(*Bot. Mag.* 6179.) *Nicotiana tabacum* var. *fruticosa*, *Lin.*—(*Bot. Mag.* 6207.) *Ornithogalum sororium*, *Schott.* *Piaranthus flavidus*, *N. Brown.* *Romanzoffia unalaschensis*, *Chmss.* *Senecio chordifolia*, *Hk. f.*—(*Bot. Mag.* 6216.) *Theropogon pallidus*, *Maxim.*—(*Bot. Mag.* 6154.)

It has been found necessary to remove the noble row of old Elms that stood by the river side at the back of the old Palace wall. One of these having been blown down during the winter it was found that it had no adequate roots, and was mainly supported in its erect position by about 5 feet of ballast that had been used to raise the level of the road; an examination of the others showed that a very heavy gale might prostrate the whole and cause immense damage. It was therefore decided to remove them at once and replace them by younger trees. This has been done, and in addition a row parallel to them has been planted on the opposite side of the path.

These trees served in a great measure to mask the gasworks and other unsightly buildings belonging to the town of Brentford. Their removal has brought into greater prominence the rapid progress to ruin of the trees and plantations upon the eyots in the river, and upon which the great beauty of the reach immediately above Kew Bridge and bounding the northern side of the Royal Gardens entirely depends. The eyots are two in number, with an aggregate acreage of 4a. 2r. 24p. Part of the most easterly of them (1a. 3r. 35p.) was in 1626 conveyed to trustees for certain charitable purposes in the parish of Fulham. In 1811 it was leased to Robert Hunter, Esq., on behalf of His Majesty George III., for twenty-one years at an annual rent of £20. From the expiration of this lease in 1832 up to 1873 the same amount of annual rent appears to have been paid to Her Majesty's Commissioners of Woods and Forests. Under the direction of the Charity Commission it was sold to the Office of Woods and Forests, the Office of Works undertaking to pay them the same amount of rent.

The receipts during the past year have been 7326 plants of all kinds, and 2811 packets of seeds from 233 contributors.

The *Eucalyptus globulus* which has been so largely distributed on account of its supposed prophylactic virtues will probably turn out to be extremely useful for its timber in countries not too hot for its growth. On the Neilgherries where Australian trees have been largely introduced, one of the most valuable, the *Acacia melanoxylon*, proves to be all but valueless owing to the ravages of various Lorantheaceous parasites. The *Eucalyptus globulus* is, however, reported by Dr. Bidie to entirely escape their attacks. He attributes this immunity to the "deciduous bark, the seeds (of the parasite) thereby being dislodged before they can germinate and gain a hold."

The production of different kinds of Caoutchouc in India continues to engage the attention of the India Office and of this establishment. One fact in connection with it which seems to require very careful consideration has been pointed out by Mr. Mann in his report on the Caoutchouc plantations in Assam. It is found that although the *Ficus elastica* will grow with undiminished rapidity and luxuriance in situations remote from the hills, it fails to yield Caoutchouc. Mr. Mann concludes that no greater mistake could be made than to start plantations of *Ficus elastica* in any part of Bengal. It appears, therefore, judging from this case, that conditions which may ensure the successful growth of Caoutchouc-yielding trees may not be sufficient to determine their producing Caoutchouc.

The Indiarubber of Para (*Hevea brasiliensis*) has already been introduced into India. It proves to be capable of easy propagation at Kew by cuttings. I am endeavouring to obtain additional supplies of the seeds, but these rapidly lose their germinating power. Hardly 1 per cent. of the seeds have hitherto reached us alive.

My attention has been drawn to the great value of the Mesquit or Screw Bean of Arizona (*Prosopis pubescens*), for the purpose of cattle-feeding in hot-dry countries. It would be, probably, extremely valuable in South Africa and Australia. I have taken steps to procure a supply of the seeds, but nearly all those at present received have been killed by the attacks of a small boring beetle.

I have received both from the "Challenger" and "Transit" expeditions seeds of the Pringlea, or Kerguelen's Land Cabbage. Although a large number of fine young plants were raised, they have nearly all perished during last summer. As a similar ill fate has befallen this interesting plant at the Botanic Gardens of Paris, Cape Town, and Edinburgh, I can only conclude that it is very intolerant of warmth. Its destruction has also been hastened by the attacks of the White Cabbage rust (*Cystopus*).

## NOTES AND GLEANINGS.

We have reason to believe that the GREAT FRUIT SHOW of the Royal Horticultural Society, which is announced in the

schedule to be held on November 8th, will be abandoned. The Council will be quite justified in doing so, thereby husbanding the funds of the Society for more important uses. The local Fellows and the public seem to be tired of shows, and it is high time that public bodies realised that fact.

— THE THUNDERSTORM of Sunday night broke over Hornsey and Tottenham with terrific force at eight o'clock, and appears to have expended itself upon the district of High Cross, Tottenham, where the destruction to property has been very serious. Scores of residences with large grounds and conservatories have suffered with a severity unexampled in the history of the village. The hailstones were the size of a marble, and not even plate-glass was proof against them. The splendid vineries of Mr. Rochford, Mr. Leschellas, and Sir Charles Reed have scarcely a pane of glass left, and the roads and gardens are covered with the debris of fine Elms and Chestnuts forming the well-known avenues near the Friends' School by Page Green. Birds were killed and lamed, and rookeries were disestablished. The poor have suffered greatly. Heaps of ice stones are still lying on the roadsides, and when examined these stones are of a green colour in the centre, while the outer crust bears a close resemblance to an acidulated ball. The market gardeners in the neighbourhood have lost all their season fruits, and damage by water is extensively reported.

— ONE of the finest sights to be seen in the way of Grape-growing at the present moment is the MUSCAT HOUSE AT MESSRS. LANE & SON'S nurseries at Berkhamsted. Frequenters of all the great exhibitions have for many years been familiar with the wonderful collections of Grapes that have been shown by Messrs. Lane, but the past presents no comparison with the present. The size and symmetry of the bunches, the size and colour of the berries, and the wonderfully even and abundant crop, are sights worth seeing. There are other houses consisting of Frankenthal, and many of the newest kinds, which are also highly worthy of inspection.

— DR. SCHOMBURGER, Director of the Adelaide Botanic Garden, has issued, as usual, his very full and satisfactory report. He states that the large trunks of *ENCEPHALARTOS* will lie for years in a dormant state before showing signs of fresh growth. "In 1873 the Director of the Botanic Garden, Natal (Mr. Keith) informed me that, by a vessel bound for Melbourne, he had sent a case with very large trunks of *Encephalartos natalensis*. This ship arrived in Melbourne; but, notwithstanding my inquiries, I could hear nothing of what had become of the case, and I believed that it had been lost or got into other hands. Nearly half a year after a friend of mine visited Melbourne, and having some business in one of the Government bonded stores, saw there a case with my address. On making inquiries he was informed that the case had arrived from Natal, and had been lodged in the bonded store and not yet claimed. I received the case about half a year after arriving at Melbourne. The *Encephalartos* showed not the slightest sign of life; the straw in which they were packed had rotted, and I gave them up for lost. They were planted, however, in large pots, and placed in one of the stove houses; but, in the course of nearly two years showing no signs of life, they were placed underneath the plant stage, where they stood another half-year, until about four weeks since, when, to my surprise, I observed the appearance of young growth, and the leaves expanded with such rapidity that in the course of four weeks they have reached the length of nearly 5 feet, show a healthy appearance, and will form two magnificent specimen plants. After being three years in a dormant state I never expected that life still remained in their large ovoid stems."

— IN reference to the CRACKING OF GOLDEN CHAMPION GRAPE, a correspondent states as a remedy that "if the lateral on which the bunch grows be cut half through as soon as the first berry cracks no more of them will crack. This and several other Vines of similar luxuriance of habit should be cropped very heavily, or else have the laterals cut just as the Grapes are taking the second swelling."

— BONES rendered soluble are one of the most generally useful of manures, and as many of our readers do not know of the readiest mode of rendering them soluble, we copy the following notes from "The World of Science":—"In a well-made mixture of wood ashes, lime, and fresh bones that is kept well moistened with manure water or house slops for six or eight weeks, the bones would probably become softened to such a degree that they could be broken-up with the spade on

turning the pile over. The larger the proportion of ashes used the more rapidly the desired change will proceed. In the description of one of the methods above alluded to, a peck of slaked lime and a peck of sal soda are added to every barrel of unleached ashes, and this mixture is packed in alternate layers with the bones in a tight box, and the whole well moistened, as usual. It is stated that with such treatment the bones will become softened in from four to six weeks, so that they can be easily crumbled with the spade. In another mode of treatment, where ashes alone are used, a few months are required to soften the bones. According to still another method of treatment a pile is made of alternate layers 6 inches thick, of bones and unslaked lime; the pile is covered with earth, and water is poured in from time to time through holes made in this covering, the whole quantity of water added being considerably larger than what is required to slake the lime; the heating of the lime, together with the action of the caustic milk of lime that results from the use of a large quantity of water, unite to convert the bones into a soft friable mass in a short time; the pile heats and ferments for six weeks or more, and it is to be inferred, though it is not so stated directly, that the operation is completed in this time. It is likely that if unleached ashes were used also in this case, together with the unslaked lime, the operation would be finished in a shorter time, and a more valuable product would undoubtedly be obtained."

"We had," writes a gentleman to us from Lincolnshire, "the most extraordinary ICE SHOWER on the 21st inst. that I ever saw in winter or any other season. The ice fell in all shapes—zigzag, indented squares, oblongs, and in all angles. Some of the pieces were  $1\frac{1}{2}$  inch wide and some an inch thick. I have made drawings of many of them. Nothing of the sort has occurred within my memory before. It was quite a phenomenon."

From many districts accounts have reached us of the disastrous result of the late thunderstorms. Glass has been broken, flowers have been destroyed, branches have been cut from the trees, and grain crops have been much injured. Yet the storms have been by no means general, for while some localities have been flooded, others not far distant from them have remained unrefreshed and garden crops are withering under the burning sun, pastures are scorching up, and the leaves are falling from many deciduous trees, owing to the long-continued heat and drought.

At the annual exhibition of the NATIONAL CARNATION AND PICOTEE SOCIETY the collections of twelve blooms must be shown in boxes of the following dimensions—from centre to centre,  $3\frac{1}{2}$  inches; from centre to outside,  $2\frac{1}{4}$  inches, outside length,  $15\frac{3}{4}$  inches; width, 12 inches; depth,  $4\frac{1}{2}$  inches; to be painted a bright green. A good exhibition is anticipated.

At Deeside, Aberdeenshire, a few weeks ago, opposite Ballater, where the channel of the river Dee divides and forms two small islets each being 300 to 400 yards long by 100 broad, the surface of both of these islets was completely clothed with LUPINUS POLYPELLOUS in full flower. It was a most gorgeous sight. On inquiring of the landlord at the hotel at Ballater how those plants had become apparently so naturalised there, he could only say they were "Lupines," and it was supposed that the roots had been thrown-out from some gentleman's garden farther up the river, and had been carried down by the river and settled in those localities.—J. F., Haddington.

[This Lupine is quite hardy and produces a large quantity of seeds, and these would soon cover a large space with plants.]

### NIEREMBERGIA GRACILIS.

SOME years ago this plant was extremely popular as an edging plant, also for hanging baskets, vases, &c. Lately it has appeared to have gone out of fashion, succulents and Lobelias being regarded as the "correct things" in edging plants. That these plants are attractive is freely admitted, but that they are so much so as to drive out of gardens Nierembergias cannot be conceded.

The chaste and compact growth of Nierembergia gracilis, its slender foliage and conspicuous yet delicate flowers, constitute it an edging plant of the first rank. Especially is it effective during the present hot and dry season—surpassing, indeed, almost any other edging plant in the garden. It appears to rejoice in heat, and drought does not harm it; and for light soils in dry districts it is certainly worthy of extended cultivation. It is a free-growing plant, and is rarely affected by insects or

disease. For window boxes, vases, and hanging baskets it is one of the very best of plants that can be employed. For greenhouse and conservatory decoration in spring and early summer large plants of it are most effective; indeed, both for house and garden culture it is a valuable plant, and when well grown will never fail to have many admirers.

A stock may be provided by taking cuttings at the present time, inserting them in sand and placing them in a close frame. These may be wintered in a light greenhouse, and be potted-off in spring; and the stock may be further increased at that time, when cuttings strike readily in heat and speedily grow into flowering plants.

As the propagating season is at hand let me urge that a few potsful of cuttings of this elegant plant be struck, and especially by those who have light soil to deal with and reside in dry localities. In such a soil and district edgings formed of this plant are by far the most satisfactory and attractive in the garden.—J. J., South Notts.

### MIXED BEDS.

By mixed beds I do not mean the old English mode of planting a great variety of plants in the same bed or border, but simply the mixing of two plants together, each of which heightens the effect of the other. Perhaps "duplicate bedding" might be an appropriate term to use, for it is filling one bed with two kinds of plants.

An occasional bed of this nature may be seen in most large gardens and public parks, and beds which have been probably so planted because plants of a given kind have not been sufficiently plentiful for forming "self" beds. They may have been planted with regret—a regret, however, which in many instances has been succeeded by admiration. I know more than one garden where mixed beds, planted in the first instance from necessity, are now systematically arranged, and the effect they produce is of the most pleasing character. Since *Violas* (Pansies) have proved so adaptable for bedding, these plants are now freely associated with *Geraniums*, and the effect of such a combination is not only extremely good, but the beds are gay during a longer period than could possibly be the case where their mixture has not been adopted. Take any of the free-flowering blue or purple Pansies and associate them with variegated *Geraniums*, and the bed is gay from the day it is planted until the season for flowers has passed away. The value of Pansies for this mode of decoration is undoubtedly great, and cannot fail to contribute powerfully to the attractiveness of a garden.

Other mixed beds are also very beautiful. Plant, for instance, a large bed with *Centaurea ragusina* and *Verbena venosa*, and it will probably be considered the best bed in the garden. The rich purple trusses of the *Verbena* resting on the silvery ground have a most agreeable effect and cannot fail to be admired. The old *Manglesii* *Geranium*, which is one of the finest of all variegated bedding plants, associated with Purple King *Verbena* makes a remarkably attractive bed; and perhaps even more rich is a combination of the same *Geranium* with Crimson King *Verbena*. *Gnaphalium lanatum* mixed with blue Pansies and purple Asters produces an effective arrangement—the Pansies doing duty in early summer, the Asters continuing their beauty into the autumn. That mixture makes a very fine bed. Yellow Pansies mixed with *Iresine Lindenii* or *Perilla* produce an exceedingly rich combination, and if white Asters are also dotted in the bed in autumn it is as attractive as it was in the summer. A bed of mixed Pansies dotted with mixed *Pentstemons* has a long and attractive charm, and is full of interest and real beauty for at the least six months. A large bed planted with these two plants alone is almost a flower garden in itself.

There are other effective mixtures, but these named have been noted as having given great satisfaction to the numerous visitors to a large and celebrated flower garden. Those having proved other combinations to be specially attractive would by mentioning them convey useful information, for this mode of occupying flower beds is, I am told by a gentleman who travels a great deal, growing and spreading.—J. McK.

### DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

#### HARDY FRUIT GARDEN.

We have in previous numbers remarked that when wall or other fruit trees are in good health there is little danger to be

incurred from thinning-out the fruit early. When the trees are overloaded with fruit a portion of it may be thrown off, but it is not so when it has been regularly thinned-out and only the best fruit left. Peaches and Nectarines have now passed through the stoning period, and if more fruit has been left upon the trees than is intended to remain for a full crop it ought to be removed at once. Plums and Apricots are further advanced, at least the earliest sorts. We have Rivers's Early Prolific now changing colour on bushes and pyramids. This is an excellent Plum, not only valuable for its earliness but also for its free-fruited qualities. Just a word in passing on thinning fruits. Many gardeners ruin their trees from a laudable ambition to grow large crops; they allow too many fruits to remain on the trees, and none of them grow to the largest size. Another great mistake is allowing the fruit to remain too long on the trees before removing that which is superfluous. The test of good culture is size of fruit combined with weight of crop, and this can only be obtained by judicious thinning. It is not impossible to overthin. A tree that would ripen perfectly, say, twelve dozen Peaches, would not produce better fruit if six dozen of them were removed in an early stage of their growth; the tree would perhaps grow too strongly, and the balance would not be maintained correctly. Much depends also upon the health and vigour of the tree. If the young growth is very luxuriant more fruit should be allowed upon a given surface than when the growth is moderate or weak. It is when trees are weak and not over-healthy that the most mischief ensues. The fruit sets more freely on such trees than upon trees of vigorous growth. The quantity of Peaches that a healthy tree of moderate growth ought to bear is one to every square foot. A tree trained to a wall surface 12 feet high by 20 feet wide would bring to maturity 240 fruit. Our dwarf and pyramid-trained trees have not yet been looked over to thin-out and cut-back the young wood; it ought to have been done, but other work has prevented it. The trees are very lightly cropped, and the fruits have not in any case required to be thinned-out.

The ground is being prepared for Strawberry plants by trenching, and the runners have been removed from the plants, but we must wait until rain comes before planting them out. To free the leaves from mildew and red spider they have been dipped in water wherein soft soap has been dissolved, some tobacco juice and flowers of sulphur also being added.

Raspberries have very nearly all been gathered, and the young canes that will bear fruit next year have made good growths. These are sometimes tied-up to the sticks at this time, but we prefer to let them hang loose, so that they may be fully exposed to the sun and air. The leaves are also frequently broken in tying them up, and the buds at the base of those leaves cannot become matured. Other small fruits have ripened very rapidly, and as no rain has fallen we had ample opportunity to gather it for preserving purposes.

#### VINERIES.

The main difficulty with Vines from which the fruit has been cut early in the season is to keep the leaves in a healthy state. Even under the best management red spider will be present to do mischief, and the leaves fall off from the attacks of this pest or other causes, the result being that the Vines will start into growth before their time, and the more young growth there is made so much the more difficult is it to start the Vines next season. To prevent this early growth the house must be kept as cool as possible. Our houses have the ventilators open to their fullest extent night and day, and any growths that are formed are at once stopped. The house is always hottest at that part nearest the glass and coolest at the surface of the border, so that it is best to lower the Vines if the leaves are shed about this time, or indeed any other plan may be tried to retard growth. The weather has been very favourable to the ripening of white Grapes. Muscats and Buckland Sweetwater enjoy plenty of sunshine; it is not quite safe to expose the fruit too freely to the sun, as the skin is frequently injured, the berries most fully exposed becoming rusty. Some time ago we were recommended to expose Muscats to the sun by pushing the leaves aside and tying the bunches up, so that they hung in a sloping position to the sun. This may do in northern districts, but in the south the berries will not stand it. Ours were sadly marred in consequence. They were intended for a fruit exhibition, but were quite unfit for that purpose. In the later houses the berries are now colouring; and in that where Lady Downe's are grown the ventilators require to be open night and day to prevent the berries from becoming scalded. There must be something peculiar in the constitution of this sort, as no other grown in the same house and under precisely similar circumstances becomes injured from this cause. Although the weather has been very sultry by day, the dewfall at night is sometimes considerable, and as the ventilators are open the Vines have the benefit of this, and no artificial heat being required it is better not to damp-up the houses at night.

Vines in pots for very early forcing ought to be matured as speedily as possible—not by starving them for want of water, but by placing the pots where the Vines can be freely exposed to

the sun. They will stand a great amount of heat at this season of the year. The footstalks of the leaves should be short and stout, and the leaves ought to feel hard and crisp in the hand, and be of a dark green colour. If they are too crowded in the house, and no suitable position can be obtained for them under glass, some of them may be removed under a wall facing south or west. The canes should be nailed against the wall without injuring the leaves; here they may be syringed and watered the same as those in the house.

#### CUCUMBER AND MELON HOUSES.

The last sowing of Melons may now be made to obtain fruit in October and November. The plants must be grown in a heated structure, and to be fairly successful they must be trained to a trellis removed about a foot from the glass. We still prefer for this sowing Victory of Bath and Scarlet Gem. The seeds ought to be sown in bottom heat, and when the plants are potted-off they should be again returned to the plunging material. When they are well established in 6-inch pots plant out in the beds prepared for them, which should be good turfy loam with the addition of a little decayed manure—about one sixth part. The mould ought to be pressed firmly about the roots of the plants when they are put out in the beds.

Cucumbers may also be sown for autumn and winter supply, and the treatment required is very similar to that of Melons; but Cucumbers delight in a richer and more open soil. It is much the best method to train the plants to a trellis similar to that used for the Melon plants. We never grow Cucumbers in dung frames now either for summer or winter supply, the fruit obtained from a trellis being so much superior in appearance to that which has been lying on the ground in a frame. One side of such fruit is often of a dirty yellow colour, and never of the lively green hue of the upper or side that has been exposed; and when they are grown for exhibition, if the judges remove the fruit to examine it all round, it would not compare favourably with that from a house.

#### PLANT STOVE AND ORCHID HOUSES.

Owing to the excessively high temperature out of doors no artificial heat has been needed in any of these structures; the plants are all making very healthy growth. Many plants again require repotting, and this is being done as opportunity offers. We shut up with sunshine about 4 p.m. when the houses have a south aspect, and an hour or more later with a west exposure. Plants that usually suffer from the attacks of red spider are freely syringed with clear water to prevent the appearance of this pest. Climbing plants, such as Allamandas, Clerodendron Balfourii, Stephanotis, &c., run rampant at this season; the growths must be thinned out, and those that remain be trained into suitable positions. Such plants in good health when in flower have a fine effect trained to wires over the plants underneath, but there are many disadvantages. If the water is applied with force from a syringe it falls on the plants underneath in the form of a heavy shower, and this repeated daily does much mischief. If the plants are not kept clean by syringing red spider attacks them and spreads on to other plants. The best way is to grow only a few branches to each plant and keep it clean by sponging the leaves with soapy water.

Cool Orchids suffer from the effects of the heat, and shading with thick canvas is injurious to the plants, causing weakly growths. Our house is now shaded after a plan which has been adopted for some years with success at the Messrs. Veitch's Royal Exotic Nursery, King's Road, Chelsea. The shading is elevated about a foot above the glass by means of stout laths running parallel with the rafters and fixed to them by iron rods about a foot in length, one at top and another near the bottom of the rafter. When the shading is held in position this way the air has a free circulation between it and the glass. We syringe some of the New Grenadan Odontoglossums and Peruvian Masdevallias overhead twice daily. Many species of Orchids are benefited by a free use of the syringe in hot weather. Cattleyas, Vandas, and Aërides ought not to be syringed.—J. DOUGLAS.

#### TRADE CATALOGUE RECEIVED.

J. Linden, Ghent, Belgium.—*Catalogue of Azaleas, Camellias, &c.*

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

ABERDEEN (Royal Horticultural Society). July 26th, 27th, and 28th. Mr. Archibald J. Rennie, 123½, Union Street.  
BRIGHOUSE. July 29th. Messrs. C. Jessop & E. Rawnsley, Hon. Secs.  
SALTAIRE. July 29th. Mr. G. A. White, Hon. Sec.  
KILSBY (Flowers). August 1st. Mr. C. E. Bracebridge, Sec.  
HEWORTH (Horticultural). August 2nd. Mr. R. H. Feltoe, Hon. Sec.  
RAWTHENSTALL (ROSENDALE). August 4th and 5th. Mr. M. J. Lonsdale, Sec.  
SOUTHAMPTON. August 5th and 7th. Mr. C. S. Fudge, 39, York Street, Sec.  
FINEDON. August 7th. Mr. G. C. Mann, Sec.  
TAUNTON DEANE. August 10th. Mr. F. H. Woodforde, M.D., and Mr. Clement Smith, Hon. Secs.

FILEY. August 11th. Mr. Walter Fisher, Hon. Sec.  
 CLAY. August 12th. Mr. Alfred Suttle, Hon. Sec.  
 CLAY CROSS. August 15th. Mr. J. Stallard, Clay Cross, near Chesterfield, Sec.  
 WESTON-SUPER-MARE. August 15th and 16th. Mr. W. B. Frampton, Sec.  
 PRESTON. August 16th and 17th. Mr. W. Troughton, Hon. Sec.  
 SHEWSDURRY. August 16th and 17th. Admitt & Naughton, Hon. Secs.  
 LEDBURY. August 17th. Mr. J. B. Massfield, Hon. Sec.  
 NORTON, NEAR STOCKTON-ON-TEES. August 18th. Mr. C. Turner, Sec.  
 MILFIELD. August 19th. Mr. G. Senior and Mr. J. Rushforth, Hon. Secs.  
 CALNE (Wills). August 22nd. Mr. H. Blackford, Sec.  
 NEWBURY. August 22nd. Mr. H. Seymour, Hon. Sec.  
 DORSET COUNTY. August 23rd (at Dorchester). Mr. A. Pope and Mr. C. Parsons, Secs.  
 CHEPSTOW. August 23rd. Mr. R. Thorn, Hon. Sec.  
 CARSHALTON, WALLINGTON, AND BEDDINGTON. August 24th. Mr. J. Baines, Leicester House, Carshalton, and Mr. W. Clark, the Nurseries, Wallington, Hon. Secs.  
 LARGES AND FAIRLIE. August 25th. Mr. D. G. Glen, Hon. Sec.  
 SEATON BURN. August 26th. Mr. R. Richardson and Mr. W. Elliott, Secs.  
 ISLE OF THANET (MARGATE). August 30th. Mr. C. D. Smith, 8, Marine Terrace, Margate, Sec.  
 POCKLINGTON. August 31st. Sec., Mr. J. E. Ross.  
 YARMOUTH. August 31st. Mr. S. Aldred, Hon. Sec.  
 THORNTON HEATH. September 1st and 2nd. Mr. W. Raines, 10, St. John's Villas, Bensham Manor Road, Thornton Heath, Hon. Sec.  
 MONTROSE. September 1st and 2nd. Mr. Alex. Burnett, 2, High Street, Sec.  
 DUNDRE (International). September 7th, 8th, and 9th. Mr. W. R. McKelvie, 26, Euclid Crescent, Sec.  
 GLASGOW. September 12th and 13th. Mr. F. Gilb. Doughall, 167, Canning Street, Sec.  
 ROYAL CALEDONIAN HORTICULTURAL SOCIETY. September 18th.  
 KILMARNOCK. September 14th. Mr. M. Smith, 11, King Street, Sec.  
 IPSWICH. September 17th. Sec., Mr. W. B. Jeffries, Henley Road, Ipswich.  
 NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (H. T. F.).—T. Hogg's "Treatise on the Carnation, &c.," and Madcock's "Florist's Directory." But you will find an epitome of all in our manual "Florist's Flowers."

PRESERVING THE SCENT OF FLOWERS (W. J. C.).—Jasmine, Rose, or any other flowers may have their scent preserved by the following mode:—Place them between thin layers of cotton wool, dipping these into the finest olive oil, and sprinkling a small quantity of fine salt on the flowers alternately until an earthen or wide-mouthed glass vessel is quite full. Tie the top close with a bladder, and place the vessel in a south aspect exposed to the heat of the sun, and in fifteen days when opened a fragrant oil may be squeezed away from the whole mass, little inferior, if Roses are made use of, to the dear and highly valued otto or attar of Roses.

STRAWBERRIES FOR EXHIBITION (G. F. W.).—As you have Sir J. Paxton and Dr. Hogg you may add to them President and James Veitch. If you cut off the leaves of Sir J. Paxton do so now.

GRAPES IN GROUND VINERY (J. J. M.).—The Grapes cracking is caused probably by giving too much water and too little ventilation. We water moderately twice a week, leave the glass partly open night and day, and never syringe. Our Grapes never crack.

GRAPES SHADED BY LEAVES (F. J.).—Unless far more numerous than usual the Vine leaves will aid instead of checking the Grapes colouring.

DRAGON'S BLOOD FOR PANSIES (Q. M. R.).—Whoever recommended such an application could not have known what he recommended. It is a resin not soluble in water.

DIVIDING PROPOSED VINERY (W. H.).—We should not divide the vinery into two compartments—i.e., one for early and the other late Grapes, which would necessitate two sets of heating apparatus, though one fire would do for both, and you would need to have a higher temperature for a considerably longer period than were the house in one compartment. Late Grapes are the most profitable, such as will hang in good condition until the summer Grapes are past.

CUCUMBER PLANTS INFESTED WITH RED SPIDER (A. B.).—The leaf sent us was smothered with red spider, many alive when it reached us. If all the leaves are in the same condition as that sent there is no hope of the plant's recovering so severe an attack. Remove the worst infested leaves and syringe the plants morning and evening, keeping the floors and every available surface wet during the day. If in beds water overhead every afternoon and shut up the frame early (about four o'clock), the sprinkling being just previously applied, and if the sun be powerful shade for an hour. Your only hope is in fresh healthy growth, removing the old leaves gradually as new growth is made.

VEGETABLE MARROWS NOT SWELLING (G. V. C.).—It usually arises from the soil being too dry. Give them a thorough soaking of water. The waterings you have given were no doubt insufficient, or applied after the mischief was done.

ANTS ON ROSE BUSHES (Red Hill).—They do no damage to the bushes, and are only found where green fly clusters on the shoots. There is a sweet substance dropped by the aphid tribe which ants are fond of, and it is solely for this that they go on Rose bushes.

ROSES (X. Y. Z.).—Bessie Johnson is an excellent light pink. Maréchal Niel and Baroness Rothschild are for outdoor culture. (G. J. Barnesby).—Such sports are not uncommon. (E. T.).—If you water the roots abundantly daily and keep the surface mulched you will probably prevent the mildew. (T. E. C.).—We cannot name any florists' flowers that have hundreds of varieties nearly alike.

SEAKALE (H. W. S. C.).—The strong seedlings may be forced next year. You mention a Rose leaf being enclosed, but it wasn't.

MANURE (E. C. O.).—As you cannot obtain stable manure you must use guano and have all the weeds and leaves rotted in a heap, pouring over it some ammoniacal liquor from the gasworks.

MELON LEAF SPOTTED (N. N.).—The brown spots are not caused by red spider. Apply a little weak tepid manure water to the roots. Keep the air moist and ventilate freely.

IVY ON CHURCH WALLS (A Reader).—Builders object because Ivy renders repairs needless. We know that it is both protective and ornamental.

AMERICAN BLACKBERRIES (G. D.).—Cultivate them as Raspberries are cultivated. Liquid manure may be given now. The surface of your heavy soil should be mulched over their roots.

STRAWBERRIES FOR LIGHT SOIL (Runner).—Keen's Seedling, President, and Frogmore Late Pine. Trench the ground and have the surface mulched.

HOLLYHOCK LEAF DISEASED (A. N.).—It is destroyed by a fungus. Abundant watering of the roots and keeping the surface of the soil thickly mulched would probably have prevented it. The old-woman-and-knife remedy is the only mode of extirpating the weeds from your lawn.

SHRUBS AND TREES FOR SEASHORE (S. S.).—Evergreen Oak, Pinus insignis, P. laricio, with Sycomore and Turkey Oak, are what we advise of trees; and of shrubs Tamarisk, Alaternus, Brooms, double Gorse, Eucynurus, Escalonia macrantha, Hollies, Elders, Sea Buckthorn, and Guelder Rose.

GERANIUMS (J. N.).—The three are handsome and vigorous. We cannot name any florists' varieties; they are too numerous, and nearly alike to others.

SHADING FOR A PLANT STOVE (J. P.).—A portable shading is preferable to a fixed one, as the former need only be used when required. We certainly advise you to use the blind, although the material is somewhat stout. It will only need to be down when the sun is powerful. By careful and correct management it will afford you considerable aid, and we should prefer it to the whitewash.

BLACK FUNGUS ON VINE LEAVES (J. M.).—We can only repeat that the vinery is mismanaged, or the leaves would not have been so severely affected. More ventilation and attention to the foliage would have banished the disease. The other plants being unscathed is no guide.

MAGGOTS IN ONIONS (Porter).—Nothing will destroy the maggots without destroying the Onions. Preventing the sawflies depositing their eggs in the bulbs is the course to adopt another year. Pull up all Onions that have maggots in them and destroy them. Every maggot will become a chrysalis and produce a parent fly next year.

NAMES OF PLANTS (Beckenham).—1, Barren, and therefore indeterminate; 2, *Asplenium diversifolium*; 3, *Davallia dissecta*; 4, *Pellaea geraniifolia*. (E. M. Body).—*Cystopteris fragilis*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### A MIDNIGHT ADVENTURE.

A FEW days ago I removed a couple of hens from broods of chicks with which they had been cooped nearly a month in a croft close by my rustic dwelling, and by an odd coincidence, if it be one, found next morning that an enemy had been in the camp during the night, for there lay within a yard of its coop the remains of a month-old chick half eaten. Some guessing took place as to who or what could have been the marauder, but my gardener was positive that "it mun ha' been that black cat o' Brown's," which he forthwith requested permission to "mak' end on," on my account of course. It was certainly suggestive that the most weakly among the several dozens of various sorts and conditions of chickens running practically at liberty about the spot should have been selected, because the fact seemed to imply that its captor had been just nimble enough to catch it, and therefore scarcely so active as a cat; besides which I thought a cat would probably have made a heartier meal than half of so small a chick, supposing it had not, cat-like, first carried it off altogether. So "that cat o' Brown's," though under sore suspicion, escaped molestation for the present—at all events till it should be seen what another night should bring forth.

The next evening the chicks were all left safe, cuddled up together in their coops pretty much *à fresco*, and with two acres of croft and garden open to them in which to scatter and take refuge in case of attack. Sure enough an attack came. A little before midnight I was roused from my first uneasy attempt at slumber—the weather being a trifle of the warmest even for July—by loud and most piteous cries from my chicks, the more audible inasmuch as the open window looked down almost straight upon their harbourage. In a very few moments I was down among the affrighted and distressed chicks in no little excitement and the airiest of costumes; but though chicks were to be heard calling all over the place, nothing, except one or two of themselves, was to be seen. There seemed nothing for it but to hope that the little creatures would be too active for their enemy and keep out of its reach; but hardly had I returned to my room before the same distressful cries arose again, and once more, costume as before, I tried to discover the nature of the foe evidently so feared by my poor chicks. As I stood beside

one of the coops a chick with its feathers sadly ruffled blundered in the semi-darkness against my slippered but otherwise bare foot. Its gait and appearance betokened serious injury as well as fright, and I groped after it as well as I could, but lost it in the adjoining hedge. Presently, however, it "rolled" into view again and I grabbed at it, to find, however, by most indubitable evidence that its "feathers" were too stiff, and especially too pointed, to belong to a chicken of such size. Only one kind of wild fowl could produce such a feeling as this one had caused in the hand that had grabbed it, and a certain shrivelling into itself and cessation of all motion about it, helped to the discovery that the creature was—a hedgehog! With the help of a bent stick he was speedily lifted into an empty tub standing near, and there left to his reflections till the morning, the capture and incarceration being effected just on the stroke of midnight. No further alarm occurred, and next morning the tub-head court-martial unanimously agreed that the prisoner below was undoubtedly the author of the late disturbance. Opinions differed as to the slaying and half-eating of the afore-mentioned chick, suspicion in a certain quarter being still strong against "that black cat;" but though the evidence as to this crime was merely circumstantial, it was felt to be so strong that the court unanimously endorsed the gardener's proposition to "cut 'is head off an' bury 'im."

Since the grim sentence was carried into effect all has been peace. But is it reason or instinct that has led all the larger chicks to leave their own free and open night quarters and crowd in with their younger brothers and sisters in the coops that are protected with wire fencing, and even the biggest of them that are unable to get through the openings wait till the fence is lifted to let them in?—W. W., *Stainton-in-Cleveland*.

### CLECKHEATON POULTRY SHOW.

THIS Show was held on the 22nd inst. The poultry pens being neatly arranged on three sides of a field, with plenty of room in the centre. This department requires revision, as also those of Pigeons and Rabbits, the schedule being somewhat antiquated.

The entries in poultry were about equal to those of last year; but in Pigeons we thought we noticed a falling-off in numbers. Single *Game* cocks were first on the list, a Brown Red being placed first, and Pile second, and for the latter we must confess a preference. Black Reds were pretty good and well placed; the Brown Reds a moderate lot; Duckwings were in nice feather. *Dorkings* only one entry. *Cochins*, Buff pretty good; but the *Brahmas* about the best class in the Show; first and third Darks, and second Light. In Pencilled *Hamburgs* first and third were Silver, and second Gold. Blacks very good and well placed; the first about perfect, were in better order than a week ago. Spangles we should have reversed, the Golden pen being more to our taste. *Game Bantams* were, as at several previous Shows, the first a splendid pen in Black Reds. The variety of *Game* only poor. In the following Blacks won the third. *Chickens*.—In the Variety class Polish won. A grand pen of Spanish were first in the Variety class. A good pen of Polish were left out on account of being claimed before the judging. One chicken class was provided; first in this were Buff *Cochins*, second Spanish, extra second Light *Brahmas*, third Dark *Brahmas*, and extra third White *Cochins*.

In *Pigeons* the first-prize Carriers, Dragons, and Antwerps, both Long and Short, were well worthy of notice; but the rest were poor.

In *Rabbits* there were only four in Lops. In bucks Any other variety the winners were Silver-Gray, the first in all respects good; the highly commended Rabbit of the same exhibitor being next best; the second only poor, and a decided mistake. Pen 5 was a nice Angora. In does an Angora was first; second a Silver-Gray, to which we preferred pen 12 of the same colour.

A good schedule would bring a good entry here.

**POULTRY.**—*Game.*—*Cock.*—1, C. Fearley. 2, H. C. Mason. 3, H. E. Martin. *whc.* W. Bentley. 4, M. Brown. 5, Black Red. 1, R. Hemingway. 2, C. W. Brierley. 3, H. C. **JUDGES.**—*Poultry:* Mr. W. Cannan, Bradford. *Pigeons and Rabbits:* Mr. E. Hutton, Pudsey. *Cage Birds:* Mr. W. Brownridge, Leeds.

### CASTLE DONINGTON POULTRY SHOW.

THE entries for this Show were considerably in advance of those of last year, but Pigeons had been knocked off, while two classes had been added for Rabbits. Last year the field was a perfect bog, but this year we had the other extreme, the sun being at scorching heat, but a spacious marquee being provided the birds were well protected, and also well watered and fed with Spratt's food supplied in small tins to each pen.

Buff *Cochin* cocks were a grand class of eight, and all noticed, and hens also good. The Partridge in both classes only moderate. In Dark *Brahma* cocks first was in fine order, good in shape, and well marked, and of moderate size. Second smaller and not so good in shape. In hens were two grand pairs, between which there was little choice; but in the second pen one was light, evidently just recovering from broodiness. Light *Brahma* hens were better than the cocks, although the first in the latter class was a good bird. *Houdans* bad in both classes. In *Spanish* the cocks were fair birds but out of feather, but the hens were good and well shown. The first were quite young hens. In *Game* cocks, Red, first was a well-known old Black Red, and second a Brown Red; and in hens, first a capital pair of Brown Red hens, and second Black Red pullets, the latter losing only by a slight tendency to duck-claw, which, however, they may grow out of with judicious treatment. In cocks, any other variety, the winners were Duckwings. Gold or Silver-pencilled cocks was won by Golden in both cases, the first a true *Hamburgh*, very good in head. Second a bright-coloured bird, but ears somewhat shrivelled. Spangled cocks, a Golden bird good in all points, second a Silver-spangle of the true *Hamburgh* type, but failing in feather. Hens, winners Golden and good. Variety class, first a Gold Poland cock, which we have seen in better order; second Malay, and highly commended Silver Polands. Hens, first the best pair of birds in the Show, and in

nice bloom; these were Black Hamburgs, second Gold Polands. The light class was very large, thirty entries. First forward Light Brahmas; second a pair of Spanish, very good; and third Dark Dorkings. *Bantams* were mixed classes. First in cocks a most perfect Black, and second Game, but out of feather; and in hens Blacks were first, and a pair of Black Red pullets second. The Selling classes were very large, and among these were some cheap birds, especially in hens, which were—first Black Hamburg, and second Dorking pullets.

In the *Ducks*, any variety, were some capital Chilian, Teal, and Carolinas.

*Rabbits* had thirty-eight entries in the two classes. Lops were exceptionally good, and the measurements given below are honest, not having half and quarter inches allowed because "it's a cold morning." First a Sooty Fawn buck, 23 by 4½ inches, and in the pink of condition; second a Black-and-white doe, a little too gay, 22½ by 5 inches; and third a Fawn-and-white, large, good head and eye, 22 by 4½ inches, not in order for hard competition, the "highly commendeds" coming well up in point of measurement. In the following class, which was devoted to all other varieties, prizes were awarded to four Rabbits which it would be difficult to beat in their own class, and many highly deserving had to be passed over with commendations only. First was a most exquisite specimen of a Silver-Cream, second a Belgian Hare nearly perfect, third a young Himalayan, and fourth an Angora; the latter had some of its down off the centre of the back. Some very good Dutch were shown, notably one very highly commended, a Fawn only six weeks old.

**POULTRY.—COCHINS.**—*Buff*.—Cock.—1, W. A. Burnell. Special 2, W. H. Crewe. Hens.—1, W. A. Burnell, 2, E. Winwood. *Partridge*.—Cock.—1, J. Gunn. 2, S. W. Hallan. Hens.—Special 1, Rev. R. Fielden. 2, Mrs. R. Story. *Any other variety*.—Cock.—Special 1, E. Snell. 2, J. Backham. Hens.—1, W. A. Burnell, 2, W. Holbrook. **BARINAS.**—*Dark*.—Cock.—Special 1, J. Long. 2, J. Gunn. Hens.—1, W. Morris. 2, F. Holbrook. *Light*.—Cock.—1, Mrs. Peet. 2, H. Feast. Hens.—Special 1, Mrs. Peet. 2, G. Breze. **DORKINGS.**—Cock.—1, E. Snell. 2, Miss Murray. Hens.—Special 1, T. Bridon. **HOLDANS.**—Cock.—1, Rev. A. Dobbin. 2, F. Holbrook. Hens.—Special 1, H. Feast. 2, J. Backham. **SPANISH.**—Cock.—1, R. Hill. 2, H. Feast. Hens.—Special 1, J. Dixon. 2, R. Hill. **GAME.**—*Black or Brown-breasted Red*.—Cock.—Special 1, J. Mason. 2, G. Richardson. Hens.—1, G. Richardson. 2, C. Spencer. *Any other variety*.—Cock.—Special 1, J. Mason. 2, D. Hulme. Hens.—1, E. Bell. 2, G. Barnesby. **HAMBURGERS.**—*Gold or Silver-pencilled*.—Cock.—Special 1, J. Long. 2, C. K. Senior. Hens.—1, C. Judson. 2, H. Kidger. *Gold or Silver-spangled*.—Cock.—Special 1, J. Ward. 2, J. Long. Hens.—1, J. Long. 2, J. E. Jones. **ANY OTHER VARIETY.**—Cock.—1, A. & W. H. Silvertown (Golden Poland). 2, J. Backham (Malay). Hens.—Special 1, J. Long. 2, A. & W. H. Silvertown (Golden Poland). **ANY VARIETY.**—*Young*.—Special 1, G. B. Breze. 2, S. W. Hallam (Dorkings). 3, T. Bridon (Dorkings). 4, W. A. Burnell (Buff Cochins). **BANTAMS.**—Cock.—Special 1, R. H. Ashton. 2, E. Bell. Hens.—1, R. H. Ashton. 2, C. Adkin. **SELLING CLASS.**—Cock.—1, C. Judson (Gold-pencilled Hamburg). 2, A. & W. H. Silvertown (Golden Poland). Hens.—Special 1, E. Leake (Black Hamburgs). 2, T. Bridon (Dorkings). **DUCKS.**—*Wiltshire*.—1, E. Snell. 2, Mrs. R. Story. *Any other variety*.—1, A. & W. H. Silvertown. 2, R. H. Ashton. **GEES.**—1, E. Snell. 2, J. Nicholson, jun. **TURKEYS.**—1, Lady P. Stanhope. **RABBITS.**—*Lops.*—*Double*.—1, C. E. Thompson. 2, E. Pepper. 3, J. A. Barrs. **ANY OTHER VARIETY.**—1, H. Gilbert (Silver Cream). 2, E. Robinson (Belgian Hare). 3, Foster & Chambers (Himalayan). 4, E. Snell (Silver-Grey). *etc.* F. Purser (Angora). T. Goltighy (Dutch).

**JUDGES.**—Rev. T. O'Grady, Ashbourne; Mr. E. Hutton, Pudsey, Leeds.

## POULTRY AND BEE NEWS AND QUERIES.

**DORKING CHICKENS HATCHED BY A PIGEON.**—Mrs. Gane, the matron of the Chippenham Union Workhouse, placed two Dorking eggs under a common Pigeon, one of the feeders of her fancy birds, and they were duly hatched, and I saw them yesterday, July 19th. Mrs. Gane had constructed a small artificial mother of flannel list, and put it in a box in the sun, and the chickens in the box. The chicks run as naturally to their artificial as they would have done to a natural mother for warmth and to be brooded. I may remark that Mrs. Gane is an ardent Pigeon fancier, a grand resource and amusement for one whose duties oblige a very constant residence at one place, as must by necessity the duties of a matron of a large workhouse. Noticing chickens hatched by a Pigeon—and in this case the eggs were of a large variety of fowl, and must have been troublesome for a Pigeon to cover—some years since a boy in this village climbed up into the rookery close to this house, took out the Rooks' eggs, and put in two from a fowl. He ascended again on the right day, and there he found two chickens. These birds I also frequently saw.—WILTSHIRE RECTOR.

The West of England Apiarian Society, by permission of the Trustees of the Pigott Estate and the Horticultural Society, will hold its first Exhibition at The Grove, Weston-super-Mare, at the same time as the annual flower show, August 15th and 16th.

## CANARY MANAGEMENT IN OLDEN TIMES.

No. 2.

In continuing my remarks from the Journal of June 15th upon Mr. Hervieux's mode of feeding and rearing young Canary birds by hand the writer further states, "Thus you see the young birds are to be fed eleven times a day without any trouble or uneasiness, the same regular hour being always observed. This last feeding [the eleventh, at three-quarters after eight for the

last time] is not always necessary, for very often the young birds are gone to rest at that time. They must not then be disturbed to feed; and if food be given to them it must be much less than at the other times, for as you may perceive there are but three-quarters of an hour between the two last feedings."

What Mr. Hervieux means by the remark "the same regular hour" I am at a loss to understand, for in one instance he allows a lapse of full two hours, and in another only three-quarters of an hour; and then he does not name at what period of the breeding season the young should have the first meal in the morning—"half-past six." This would be a late hour during June and July for young birds to be fed. From my own observations during the past week I noticed one morning in particular the parent birds feeding a nest of young at four o'clock. On the other hand, half-past six would be too early at the commencement of the breeding season; the want of sufficient daylight would prevent the birds being disturbed and fed so soon even as at that time.

But I will not be too critical in my remarks upon the chapter, which contains a few hints worthy the notice of those who may be well up in the fancy. The writer further says, "You must make a little stick very smooth and thin at the end to feed them with; it must be as broad as your little finger. Those who make use of a quill cut for that purpose have more trouble in it, because their composition not being liquid, the quill bends and is not stiff enough to take up the birds' food. You must every time give them their beak full about four times, that their craw may not be too full, which might choke them. I must also observe that there is more trouble in not following this rule than in keeping it; for besides that things do not answer so well, a man is every moment in pain to know how long it is since they were fed, and being thus concerned he goes to the little birds, who as soon as they see him do not fail to gape wide, though they have no occasion, for they would crave every half hour if they were to be regarded; then in pity you are apt to feed them, and commonly many of them die of it. . . . Those who will observe this method with their Canary birds will perceive them to thrive visibly and by degrees grow so strong and healthy that the moulting, which is their most fatal distemper, will not affect them."

Wholesome food and fresh water provided daily, with cleanliness of cages and fresh nests, more particularly during hot weather, are points to be observed over the rearing of young birds, without which neither Mr. Hervieux's fixed rules or the advice of others will avail. Again, the writer says, "After twenty-three or twenty-four days you are to forbear feeding them by hand, especially when you observe them to pick well of themselves. As for the lemon colour and mottled, you must continue feeding them thirty days, for they have much ado to learn to feed themselves. A more particular care must be taken of these birds than of others." In another part of the treatise the writer speaks thus of lemon-coloured or jonquil birds, "The young which come from the race I have spoken of are much more troublesome to rear than all other sorts, as being of a very tender constitution."

"When they (the young) first begin to feed alone put them into a cage without perches, with a little very fine small hay or moss well dried on the bottom of the cage. The first month they feed alone give them bruised hempseed, yolk of egg boiled hard, some simnel or biscuit very dry and grated, water with a little fresh liquorice in it, and a little very ripe chickweed, each of them apart in the middle of the cage."

In another chapter I will quote Mr. Hervieux's method of making a composition or paste for Canary birds.—GEORGE J. BARNESBY.

## COMB FOUNDATIONS.

THE latest apian excitement with our American cousins is a craze for comb foundations, and they have a pretty wrangle in progress as to some patent rights claimed both for using and making artificial combs, although it has been demonstrated that before the date of any American patent, impressed wax sheets were known and used in Europe. A sample of worker-comb foundation that I have seen is certainly of beautiful workmanship, rivaling the work of Nature's pupil the bee; but according to report the bulk used to execute orders is not equal to the sample. The sheets are made to any size, even in continuous rolls, and are intended to fill the frames, but the same flaw in their use is found as was the case with Neighbour's sheets—that is, a liability to become baggy as they are thinned by the bees. The bottom wall of the cells are accurately impressed, and surrounded by shallow hexagonal walls which the manufacturers claim sets the desirable worker pattern, and the walls furnish enough material for the bees to raise the structure to the requisite height. "NOVICE," the energetic editor of "Gleanings in Bee Culture," is manufacturing comb foundations of a mixture of solid paraffin and wax for cheapness' sake, but the low melting power of the former material has brought a difficulty that the cells from the mere weight of material

become oval instead of hexagonal. We all know the exquisite delicacy and lightness of newly-made unsoiled comb. I am afraid to estimate its weight, but certainly it would run considerably more than 4 square feet to the pound. That, "Novice" states, is the desirable weight of his comb foundations, which costing a dollar per lb., makes the expense of filling a Woodbury hive about 7s.—far too costly for general use in England.—JOHN HUNTER, *Eaton Rise, Ealing.*

### HONEY PROSPECTS.

"A CORRESPONDENT wishes to know what is the prospect of the honey crop this season?"

It is to be hoped that many of our readers will send their experience in bee-keeping to the pages of this Journal. I am in the habit of gathering up the results annually of some of the most successful apirians in England and Scotland, and presenting them to our readers every autumn. At present I can speak about this district only. Until the middle of June the season was the worst for bees I ever remember. Since that time they have done pretty well. Our stocks rapidly rose in weight before swarming, and now, three weeks after swarming or thereabouts, we are turning the bees out of the stock hives into empty hives. We obtain about 100 lbs. of excellent honey from every five stocks. The first swarms, though late this year, are doing well. The flowers are later than usual, as well as the swarms. We have still the chance of three weeks on the clover, and afterwards three weeks on the Derbyshire moors. A run of fourteen days of fine weather on the heather gives bee-keepers splendid harvests of honey.—A. PETTIGREW.

### ONE STOCK OCCUPYING TWO HIVES.

ONE of my stocks of bees are now displaying a most singular freak. They are working in two distinct hives as one colony. To enable your readers clearly to understand how this happened, I may state that part of my apiary consists of a closed house furnished with Woodbury bar hives arranged side by side. One of these hives contained a very weak stock, which, being very old, I allowed to take its chance. The bees have gradually diminished in numbers until the 12th inst., when I found the last of them (about a score) dead on the floorboard, and not a particle of honey in the hive. I immediately closed the perforated zinc slide at the entrance, intending to remove the hive next morning; I accordingly proceeded to do so, but first opened the top of the hive, and was surprised to find a number of very active bees inside. I then discovered the slide was not quite closed, and that the bees from the adjoining hive had taken possession. I immediately opened the slide again, imagining that a new colony had located themselves there; I, however, soon discovered that both hives were really being worked with one distinct stock of bees. They are now depositing honey in the old combs, and running (not flying) to and fro between both hives in the most friendly manner. The bees now in possession are very strong. They have completed a 30-lb. super, and to give them more room I recently added a bell-glass; notwithstanding this, upwards of two quarts of bees were clustered outside the hive previous to their taking possession of the other hive, although they are completely shaded from the sun. I imagine that the bees, finding this hive empty and being deficient of room, resolved on using it as a storehouse. I have kept bees for many years, but have never seen or heard of a similar case; perhaps some of your readers may.—W. BUCKENHAM, *Longleat.*

### HONEY HARVESTED BY SECOND SWARMS.

ON the 2nd of this month we had two second swarms from 18-inch Pettigrew hives. As they did not seem very large, and it was so late in the season, we put them into a 13-inch hive. As they appeared rather crowded a super was put on two days later. On the 13th the gardener observed the bees hanging out, but as I was absent from home nothing was done. I returned on the evening of the 17th, and on the 18th the super containing rather more than 10 lbs. of the most perfect honeycomb was removed, the hive being also perfectly full. I should mention the bees were put into a perfectly empty hive and super, not even containing guide comb, and had no feeding. The hive has now been placed on a 16 inch nadir, and the bees appear to be working harder than ever. I should like to know if the hive should be left on the nadir till the end of the season, we have no heather near enough for the bees to visit, or if it may be removed sooner? Judging by the size and weight of the super we guess the hive to weigh between 30 and 40 lbs.—A. CONSTANT SUBSCRIBER.

[The second swarms referred to above have been larger than our correspondent fancied. They have done exceedingly well, and we are greatly obliged for her letter, as it contains a lesson of permanent and practical importance—namely, the possibility of getting supers filled on second swarms or turn-outs before

their queens begin to lay. In the pages of this Journal we suggested this three years ago. Young queens unfertilised go with second swarms, and in about ten days after they begin to lay. Sometimes it is fourteen days before an egg is deposited. Our correspondent's experience, and the record of it so inartificially given, will I trust be of considerable advantage to her and many of our readers. She has done well, too, in nadiring the hive, which will in a short time be well filled with honey and ready for removal from the nadir. About the 1st of August a batch of brood will issue from the cells, when the hive may be removed for honey. We have known two swarms join each other in natural swarming, and, of course, were hived as one. They filled their hive quite full, and sent off a virgin swarm on the eleventh day after being hived.—A. PETTIGREW.]

### SYSTEMS OF MANAGEMENT.—No. 5.

#### NADIRING AND EKing.

IN closing our last letter (the one on supering) we forgot to state that broad shallow hives are better for honey-gathering than deep hives, and that honeycomb is also more easily cut from them. For breeding purposes we have always considered that deep hives are better than shallow hives.

Nadiring is simply the placing of empty hives beneath full hives, and closing the doors of the upper hives. It is a simple mode of enlarging hives, which does not always prevent swarming. When both stocks and honey are wanted nadiring is resorted to. It answers best with first swarms when they have filled their hives with combs and need enlarging. In some instances we have seen it answer well with non-swarmer. In seasons rather unfavourable for honey-gathering the nadired hives did better and yielded more honey and better stocks than the hives that swarmed. With all kinds of hives the nadiring principle can be acted on. It is as complicated as supering, but more natural, inasmuch as bees like to work downwards. It gives more scope for breeding than supering, and is therefore better for multiplying populations. But very often bees build far too much drone comb in nadirs, and this is one of its greatest drawbacks, causing many bee-farmers to think twice before they introduce nadirs to their apiaries. Though we ourselves use nadirs, we would not suggest their general adoption. With early swarms and hives that are not ripe for swarming at the proper season, nadirs are sometimes used with advantage. Thus the nadired hives yield honey, and the nadirs become stocks.

Eking is a mode of enlargement which receives special regard in our apiary. It is to us of far more importance than either supering or nadiring. It is less complicated and more natural than either of them. Bees do better in one apartment than in two or more; they gather 8 lbs. in ekes for 2 lbs. in supers, and breed faster. In a former letter it was seen how we obtained honeycomb enough in good seasons from swarms in large hives without supers. Where super honey is the object of bee-keeping, supers are largely used. With us, and most bee-farmers, profit is our aim, and we find eking is safer and more certain than supering, and quite as profitable. But in some districts there is but little demand for run honey; here we readily sell all the bees can store up at 1s. 3d. per lb. for clover honey, and 1s. for heather honey. It is retailed out to our neighbours at these prices, which makes bee-keeping as profitable as anything else in our way. Virgin honeycomb we sell at 1s. 3d. and 1s. 6d. per lb.; wax at 2s. per lb.

It is not often that ekes now-a-days are used to prevent bees from swarming too early, for if swarms are obtained very early where there is not good pasture for them, a few pounds of sugar-syrup given to them will not only prevent discouragement and collapse, but give them an impulse at the commencement of their career which will not lose its power till the time of harvest. When sugar was higher-priced we have known the first ripe hives eked to prevent very early swarming. Since sugar has been cheap we take all the early swarms we can. In honey seasons both swarms and stocks require ekes or other enlargements, and the interest and aims of the bee-master must determine whether supering, nadiring, or eking be resorted to. In the absence of straw ekes riddle-rims may be used for enlarging hives. Square wooden hives may be enlarged by ekes of wood made to fit. In placing ekes beneath hives they should be securely nailed to them.

Almost all the salient points of practical management have, I think, been briefly noticed in this series of letters. The intelligence of the reader will enable him to compass and comprehend details and modifications which have been left out for the sake of brevity. I will finish as I began, by saying it is wise to have a definite system and to develop it as fully as possible. All bee-farmers should aim at an annual profit of £2 per hive. Some years bees yield very little profit, and some years £3 and £4 per hive. When very fine seasons for honey come, filling the hives to repletion, it is wise to take the honey from all the hives and create a stock by feeding the bees. In the year 1864 nine stocks belonging to a friend yielded £55 worth of

honey. His expenses amounted to £15, chiefly for sugar to create a stock to succeed those taken for honey. I reckon 40 lbs. of honey annually per stock hive for a run of seasons a satisfactory and fair return.

The system of managing bees which we have so often recommended and so long followed will be practised till the end—namely, large strong stocks, first swarms from them as early as possible, two harvests of honey in good seasons, the first from stock hives three weeks after swarming, and the second from the heavy hives (all beyond 60 lbs. weight) in September. At the first harvest the bees will be driven into empty hives to find for themselves, and in September they will be united to the hives kept for stock, or fed into stocks themselves. Though we like to have second swarms or casts we shall not seek them, for most of our hives go from home during the swarming season and are managed with the least possible attention.

But whatever system of management my readers may adopt or follow, let it be firmly and intelligently grasped, and diligently carried out and developed, for bee-keeping does and will pay. Amateurs as well as farmers should have a definite system, and be determined not to be unduly influenced by every wind of novelty.—A. PETTIGREW, *Priory Vineyard.*

## OUR LETTER BOX.

MRS. TUPPER (J. S.).—Not having inserted any of her communications we think it needless to copy the warnings of our American contemporaries that the unfortunate lady is not responsible.

ORNAMENTAL GOOD LAYERS (*Whaley Bridge*).—Silver-pencilled Hamburgs. Your strawberries are over-luxuriant; the soil too rich probably. Continue the mowing-off the leaves.

GREEN PARAKEETS (*Amateur*).—Keep your partly moulted bird free from draught. Nothing will conduce more to bring about good plumage than keeping birds in a cleanly condition and supplying them with wholesome food. If the Parakeet you speak of is one known as a "Bengal" you may expect the plumage not to be so bright a green as an Australian Parakeet, although of a more confirmed green colour. You may supply the birds with Canary and hemp seed, with the addition of grass seeds to the bird if a Grass Parakeet. We will give you a hint or two on exhibiting in our next issue.

FOOD FOR BULLFINCHES.—MUTILATION OF FEATHERS (*A. B. G.*).—Those who keep Bullfinches in London have not the facility of obtaining berries and buds of various kinds as food equal to those in rural districts, and as your request is for the "best green food for Bullfinches in London," we advise you to give your birds occasionally watercress, grass seeds, small salad, and a bit of apple in addition to the steeped rape seed and hemp. Furnish the latter sparingly, as it is so heating and affects Bullfinches more than other kinds of cage birds. Many instances are known of blindness or change in colour of plumage and a general wasting away occurring through a free use of hemp. Exceptions still may be found to the contrary, and much depends upon the bird's constitution and varied and confined temperature. We certainly think birds must possess extraordinary appetites when, as you ask the question, "they begin to eat each other's feathers." Apparently they may appear to be so doing. If a new quill feather should be ruthlessly drawn from a wing or tail Bullfinches and other small cage birds will extract from the stump a moisture which one might imagine was a savoury treat to them to judge from the pains they bestow to "chawel" up the quill end. It is a very common occurrence for birds to pluck and destroy each other's feathers in confinement, and the habit once acquired can only be effectually prevented by separating the birds. Many old birds (Canaries, for instance) will begin to mutilate their young as soon almost as they leave their nests, when the budding tail quills are fully charged with moisture. Birds also acquire this destructive habit to each other when the plumage is out of order or any of the feathers are disarranged, especially during the moulting sickness. We have ourselves had an instance of feather-mutilation within the past few days—that of a Mule (a pied one not to be despised either), having its flight feathers curled with the constant pulling at them with the beak of another Mule as effectually as though done with a hairdresser's curling-iron. Our remedy to straighten such feathers is to dip them in hot water for half a minute and draw them betwixt the thumb and finger, afterwards to let the birds have the benefit of a "fly" cage where they can freely bathe. Birds when limited to space are more apt to disfigure each other's feathers.

PARROT SELF-PLUCKED (*J. J. P.*).—All the varieties of Parrots are fond of gnawing, and when not able to gratify this natural propensity they bite off their feathers. To prevent your bird destroying its plumage, fasten a piece of wood inside its cage with wire, with which you will find it will amuse itself. Change its food as often as possible by giving it fruit, boiled rice, nuts, &c., and a little magnesia might be occasionally put into its drinking trough.

MOVING HIVES TO THE MOORS (*F. D.*).—The nearer bees are placed to their pasture the more honey will they gather; but at half a mile distant from a good field of heather they will collect large stores of it, weather permitting. Bees find and work on good pasture a mile distant from their homes.

COMBS MELTED (*Smallwood*).—The fact that the combs of your hive have fallen down, with honey running out and the bees clustering outside of your hive, is proof that it has not been sufficiently protected from the rays of the sun during the late very hot weather. We are sorry you have not had confidence and courage enough to put the bees into a fresh hive and take the honey at the time. In doing it now you will probably find an unsightly mess of smothered bees and broken combs inside. First get a bit of old fustian cloth or old cotton rags rolled together like a candle, and fire it at one end to smoke as much as possible, but not to blaze, and blow the smoke on the clusters outside and brush them all into an empty hive; then blow the smoke into the hive and turn it up. If all the combs are on the board, lift the combs singly and brush the bees into the hive beside those that were outside. Of course you will remove the super before you turn up the hive. With plenty of smoke and a little courage any novice could do this. There will be found much loss in this breakdown, even if the honey has not been taken by other bees in your neighbourhood. The sooner you take what honey

you can, and set your bees to work in another hive, the better it will be both for you and them.

MARRIOTT'S HIVE (*Triceps*).—Your swarm of June 1st in this hive seems to be doing well, and no doubt the bees had killed off their drones before the late splendid weather set in. Their being busy and noisy at night indicates prosperity. You may give them the wooden hive you speak of, but they will hardly make use of it. We should prefer eking the super.

PRESERVING PEAS GREEN (*J. Taylor*).—Pick them when full grown, shell them, dry them gently but thoroughly, and then store them in canvas bags in a dry place. When required for use soak them in water for a few hours until plumped-up, and then boil them. The following mode has been reported to us by a person well qualified to judge of such matters as being very successful:—Carefully shell the peas, then put them in tin canisters, not too large; put in a small piece of alum, about the size of a horsebean, to a pint of peas. When the canister is full of peas fill up the interstices with water, and solder on the lid perfectly air-tight, and boil the canister for about twenty minutes; then remove them to a cool place, and they will be found in January but little inferior to fresh newly gathered peas. Bottling is not so good—at least, we have not found it so; the air gets in, the liquid turns sour, and the peas acquire a bad taste. If any of our readers know of a successful mode of preserving peas green we shall be obliged by their communicating it to us.

## REMARKS.

19th.—Rather dull morning, warm and fine all day; rather more damp than it has been lately.

20th.—Very fine and hot all day, and starlit night.

21st.—Misty early, but clearing off before 9 A.M.; a fine and very warm day.

22nd.—A splendid hot bright day; particularly warm in the evening.

23rd.—A slight rain between 9 and 10 A.M., then fine till 3.15 P.M., when a slight thunderstorm commenced, lasting to 8.50, but it was very slight, and very distant to the north-east; the remainder of the night was very fine.

24th.—A comparatively cool day, with occasional sunshine and very bright night.

25th.—A very fine day, much warmer than yesterday, especially in the evening.

Slightly cooler than the previous week, but very fine summer weather, with only one trifling shower. Since June 23rd less than a quarter of an inch of rain has fallen.—G. J. SYMONS.

## COVENT GARDEN MARKET.—JULY 26.

THERE is no alteration in the prices to report from last week.

From observations taken near London during forty-three years, the average day temperature of the week is 74.6°; and its night temperature 50.4°.

## THE CARNATION AND PICOTEE.

At the July Show of the Royal Horticultural Society a small bank of cut flowers about a score yards in length attracted much attention; they were first-rate examples of the beautiful flowers cultivated and cherished by the old florists—namely, Carnations and Picotees. It is many years since they were so well shown, and when these good old flowers are brought out as they ought to be they are as much admired as ever they were;

and those who know the Carnation and Picotee well will join with me in saying that they were better shown than the popular and easily-grown zonal Pelargonium, notwithstanding the fact that this last-named plant has a Society formed for the express purpose of collecting money to give in prizes for it, and which on the above occasion were distributed with no sparing hand. Indeed so badly grown were the Pelargoniums that the Judges had in many cases to withhold the prizes; while in the Carnation and Picotee competition some that were placed second and third well deserved a higher position.

We would fain cherish the hope that the metropolitan societies will continue to encourage the culture of Carnations and Picotees by giving liberal prizes for them. When the first exhibitions were inaugurated at Chiswick these flowers were placed in the same position (social position would be the better expression) as Grapes, Pines, and stove and greenhouse plants. In 1833 we read that Mr. George Glenny of Twickenham, Editor of the *Horticultural Journal*, received a gold Banksian medal for Carnations and Picotees, and a large silver medal was also given to Mr. Hogg of Paddington for blooms of these flowers. The florists at that time knew the properties of the flowers, and right well did they grow them up to the regulation standard.

At that time a sub-committee was formed to draw up rules by which florists' flowers should be judged; their names were James Twitchett, Richard Headly, Adam Fitch, Fred. Finch, Samuel Widnall, and Edward Catling. The following relate to Carnations:—"The flowers large, consisting of a number of well-formed petals, neither so many as to give it a crowded appearance, nor so few as to make it appear thin and empty; the petals broad and stiff, the guard petals well rounded, and should rise a little above the calyx and then turn off gracefully in a horizontal direction, supporting the interior petals, which should gradually taper towards the crown. Bizarres must have three colours in every petal; flakes two colours strong and bright, the stripes clear and distinct; the fewer freckles or spots the better; all the colours nearly equal, or the most brilliant colour should predominate, the white pure and bright. Picotees the same qualities as to size, petals, crown, and clear white ground as the Carnations; edge of the petals smooth and well rounded. Those flowers which are free from blotch or stripes down to the petal, below the coloured edging, are greatly to be preferred to those which are marked and pouncy."

The florists of half a century ago used to grow their Carnations and Picotees in beds, being very careful to prepare a suitable compost for the plants. At the present time nearly all the best growers for exhibition cultivate their plants in pots, and in this way they are very much more under the control of the cultivator. Nor is it necessary to use very large pots. A pair of plants may be potted, the weaker-growing sorts in 8-inch and those of stronger growth in 9-inch pots. The plants are now ready for layering, and the grass this season is remarkably strong. There is a very great demand for this class of plants, and the trade cultivator will most likely layer all the grass he has; but it is not necessary for the amateur to do so, although it is well to layer a good many more than is actually required, as a number perish from the attacks of wireworm and other causes between the time of layering and potting into the blooming pots in March.

Layering is commenced by having ready a sufficient number of pegs either cut from small sprays of Elm, Beech, or Hornbeam. The stems of the common Bracken (*Pteris aquilina*) also answer well. An inch of the surface soil in the pots is removed and some fine sandy soil put in its place; the lower leaves are then stripped from the grass, then with a sharp knife cut a notch upward through a joint into the centre of the stem, then peg the layer into the soil, the peg to be placed close to the notch. The base of the layer should be about half an inch in the soil. After the operation is complete water with a fine-rose water-pot. The layers will be well rooted in a month or six weeks, when they may be cut from the parent plant and be potted two plants in large 60's or small 48-sized pots. The soil for this potting ought not to be too rich, as the plants do not winter well in rich soil. They ought to be placed in a cold frame, and the lights should be kept close for a week. Air should be gradually admitted after this until the plants endure the removal of the lights altogether without flagging. All the attention required now is to see that none of the plants suffer for want of water. Remove all dead and decaying leaves, and the lights should also be removed whenever the weather is dry and mild. Damp is the desperate enemy of the Carnation and Picotee in winter, and does infinitely more damage to the plants than frost.

When the plants begin to grow in the spring is the signal for potting them into the blooming pots; this will be from the middle to the end of March, or even in April. The requisite compost is very simple. Good sound yellow loam four parts, one part of leaf mould, one of decayed manure, and one of sharp river sand will grow the plants perfectly. This ought to lie in a heap through the winter months, and should be torn in pieces by the hand before using it, which gives an opportunity to pick out any wireworms that may be in the loam. When it is not convenient to place the pots in glazed frames after the plants are potted it is better to delay the operation until April, or if it is done in March the weather ought to be mild. A period of cold wet weather would seriously injure the plants if they were exposed to it before they

were established in the new soil. Water should also be applied carefully at first, or until the fresh roots penetrate the new soil. After this time, and if circumstances are favourable, the plants will soon spindle for bloom. The sticks that are placed to the strongest-growing sorts ought to stand 3 feet out of the soil; the weaker sorts ought to have sticks from 2 feet to 30 inches in length. As the stalks increase in length they should be tied to the sticks. Green fly is often troublesome, and should be destroyed by being dusted with snuff or Pooley's tobacco powder. This lively pest is best destroyed by fumigating when the plants are in frames. It ought, however, to be mentioned that a heavy dressing of tobacco smoke will injure the newly formed leaves in early spring. The culture of this fine flower is so simple that the above short details supply all that is necessary. During hot weather in May and June syringing overhead once or twice a-day is desirable, and the plants look much brighter for it, especially in the smoky precincts of large towns. The Carnation and Picotees are well adapted for cultivation in the smoky atmosphere of our large towns and cities, which is an additional mark in their favour.

I may as well add a list of the best sorts to cultivate, and the beginner will find that a few of those best adapted for exhibition are very shy to produce grass. Still some sorts that are shy at Loxford are not so with Mr. Charles Turner of Slough, or with growers in the north, and it will be of the most service to name those with the best flowers. The beginner will also find another source of disappointment in the fact that one or more of his best pairs of flowers will be what is termed "run." The Carnations will come minus the white, and sometimes a pair will come both self. In this case there is no way out of the difficulty but to purchase again. Many of the fine old sorts of Carnations and Picotees are not now in existence, and others are very scarce indeed. In recent years, however, some very fine flowers have been introduced, and they can easily be obtained in the trade. The best Carnations are, *Scarlet Bizarres*: Admiral Curzon (Easom), Campanini (Turner), Dreadnought (Daniels), Guardsman (Turner), Lord Lewisham (Bunn), Lord Ranelagh (Holliday), Mercury (Hextall), Mars (Hextall), Sir J. Paxton (Ely). *Crimson Bizarres*: Albion's Pride (Headly), Colonel North (Kirtland), Eccentric Jack (Wood), Isaac Wilkinson (Turner), Lord Raglan (Bowers), Marshal Ney (Headly), Rainbow (Cartwright), Rifleman (Wood). *Pink and Purple Bizarres*: Falconbridge (May), James Taylor (Gibbons), Purity (Wood), Sarah Payne (Ward). *Purple Flakes*: Ajax (Turner), Dr. Foster (Foster), Earl of Wilton (Holland), Earl Stamford (Elliot), Juno (Baldon), Mayor of Nottingham (Taylor), Premier (Milwood), True Blue (Taylor). *Scarlet Flakes*: Annihilator (Jackson), Mr. Battersby (Gibbons), Sportsman (Hedderly), Superb (Ingram). *Rose Flakes*: James Merryweather (Wood), John Keet (Whitehead), Flora's Garland (Brook), Lovely Ann (Ely), Mr. Hextall (Turner), Rose of Stapleford (Headly), Samuel Newman (Hooper), Sybil (Holmes).

**PICOTEES.**—*Red-edged*: J. B. Bryant (Ingram), Leonora (Fellows), Lord Valentinia (Kirtland), Miss Small (Fellows), Miss Turner (Taylor), Mrs. Bower (Bower), Mrs. Hornby (Turner), Mrs. Keynes (Fellows), Princess of Wales (Fellows), Wm. Summers (Simonite). *Purple-edged*: Alliance (Fellows), Chanticleer (Fellows), Cynthia (Turner), Ganymede (Simonite), Mary (Simonite), Mrs. Little (Hooper), Mrs. May (Turner), Mrs. Summers (Simonite), Norfolk Beauty (Fellows), Picco (Jackson). *Rose and Scarlet-edged*: Edith Dombrain (Turner), Ethel (Fellows), Juliana (Turner), Lucy (Taylor), Miss Meeking (Kirtland), Miss Williams (Norman), Mrs. Allcroft (Turner), Mrs. Fordham (Turner), Obadiah (Kirtland), Purity (Payne).

I have grown nearly all the above sorts, and can confidently recommend every one of them.—J. DOUGLAS.

## CABBAGES.

THE value of Cabbages and of a good breadth of them throughout summer and autumn is known to every gardener. It appears, however, that the importance of an early crop of this vegetable is not manifest to a majority of growers for home consumption, especially those with small or cottage gardens. Everyone of course grows Cabbages, but if I may judge from the demand for plants in spring, they plant when the crop is well nigh in, if cutting has not taken place in most gardens of any pretension to the name. We have, it is true, many owners of small or cottage gardens equally forward with their crops as in the best-managed garden. Those will bear me out in pointing to the importance of a batch of

Cabbages to come in when the old Potatoes are running or run out, and the new crop not in. Under the present general practice of spring planting, the Cabbage crop is not of much profit ere the Potato crop is plentiful and good. Were autumn instead of spring planting practised, nice heads would be forthcoming in a majority of seasons through May and June, and the same plants will give a quantity of sprouts equally tender and good and little later than spring-put-out plants.

It is important that the most be made of every inch of ground, and to none is this of more consequence than the cultivators of small plots of ground. In fact it is becoming an institution in gardens containing acres of ground to have a sort-of-between crop: Peas sown between the rows of Spinach or Radishes, both being off before the Pea haulm is of a height to injure the latter; and these are barely off before a Celery trench is made and planted between each two rows of Peas. The crop of Peas is made more difficult of gathering, but the prospective value of the Celery crop makes its surmounting comparatively easy. After the Celery I take Onions, and after the Onions plant with Cabbages.

I was at one time given to plant on warm borders the earliest bed of Cabbages, selecting a dwarf variety, turning-in quickly and hearting well, of which there is no better than Veitch's Improved and Atkins's Matchless. St. John's Day Cabbage is a very compact grower, and forms solid heads, coming in early. It is also very hardy. I have, however, abandoned planting on warm borders, an open situation being found preferable; but a position exposed to cutting winds is not desirable, for considerable injury is often done to the crop by the wind blowing the plants about. The best means of preventing this is to sow thinly; to prick-out, when the plants have a rough leaf with another showing, 3 inches apart, and plant before the plants become gross or drawn; and if this be attended to they will have next to no leg, with the leaves propping-up the plant all around.

Now, I only make but one summer sowing, and this from the 10th to the 15th of July, at least I only depend upon this sowing with the succeeding sprouts to carry us through summer to autumn; but I sow again the first or second week in August, generally 10th to 12th, and the plants are pricked-out in beds in September or early October. At this time the Red, of which there is none better than the Dutch for pickling, is sown, the plants being subsequently planted-out in March or early April. The plants from the August sowing are useful to meet a demand for plants in spring, everybody on most estates having plots of ground, and a gardener has generally pleasure in distributing a few plants. The autumn planting of Cabbages from seed sown in July is regarded with suspicion by many cottagers, the fear being that the plants will "run." I do not have any plants run to seed, which may arise from the plants being early planted, spindly plants never being good at any time; the plants must be stout and sturdy. I find that if the planting be delayed, that the plants lose the lower leaves, and every leaf lost is loss of so much heart.

If hearting Cabbages be wanted all the summer through, the August-sown planted in March or April will form an excellent succession to the July-sown plants; but, as before stated, nice hearted sprouts are just as good as Cabbages the size of half-a-dozen sprouts, in fact are more esteemed. A good breadth of Cabbages, be they only sprouts, are not despicable to fall back upon in case of a scarcity of greens. I remove every third row of Cabbages after cutting, and sow, after well manuring, late crops of Peas, leaving the two intervening rows of Cabbages for sprouts. The Peas and Cabbages will be off in autumn in time for manuring and throwing up roughly for the winter, and Potatoes may follow or any root crop. For a late crop of Cabbages I sow the beginning of April, and plant when fit to plant in June. They will give fine heads in late summer and autumn until frost, for though slight frost may not injure the crop, a severe one destroys it. I always manure the ground, no matter what it may have been cropped with, so soon as the ground is cleared, dig it well, and it is in a fitting state for cropping at once.

When planting the plants are scrutinised for club. If any are found with a knob or excrescence on the stem it is opened and the grub destroyed; the plant is then as good as any. A dressing of quicklime is given about the end of September to the beds planted early in the month. It is sprinkled over plants and the whole of the surface, making the ground quite white, and is good against slugs, and when fit the plants are well earthed-up. A dressing of soot is also beneficial in March or early April. When the heads are cut the leaves are

left on for a week or ten days, as this materially assists the sprouts, after which the old leaves are all cleared away.

Hill's Dwarf Incomparable, Nonpareil Improved, and Wheeler's Imperial are the best for early, and excellent at all times; Enfield Market and Battersea, with Cattell's Reliance, are larger—fine for general crop; Cocoa Nut (Wheeler's) is very early, turning in quickly, attaining a good size, and is the best-flavoured of all, though Little Pixie, a dwarf sort, is excellent in that respect; Atkins's Matchless will do in rows 15 inches apart and a foot asunder, also Little Pixie; the early crops 18 inches apart, but if to remain for sprouts 2 feet, the latter distance being allowed for the main crops.—G. ABBEY.

## AUTUMN PROPAGATION OF BEDDING PLANTS.

WHENEVER there are any great quantity of tender plants bedded-out in the summer time, their propagation in autumn always requires considerable attention. The sooner cuttings of many plants are put in after the beginning of August the better, as then they have a chance of rooting early and growing into plants that will stand wintering without loss. In many instances autumn propagation is delayed as long as possible, as taking the cuttings from the flower garden damages its appearance for a time. Geraniums are always largely propagated in autumn. Most people are in the habit of rooting their whole stock for the following season at this time. This is very advisable, as unless Geranium cuttings are rooted very early in spring they never make good plants at bedding-out time, and there are always more cuttings to be had in autumn than in spring. Before beginning to take off any cuttings everything should be prepared for putting them in and proceeding uninterruptedly with the work when it is commenced.

The first thing to do is to make ready a quantity of soil. This should consist of light loam, leaf mould, and silver sand mixed well together. The mixture above mentioned is suitable for nearly all kinds of cuttings. When the soil has been prepared, the pots, boxes, or whatever the cuttings are to be put into, should also be in readiness. Where wintering accommodation is scarce the cuttings must be put into whatever will hold most in the least space. Geranium cuttings keep well in pots, but pots cannot be so closely packed together as boxes. For all kinds of green-leaved Geraniums deal boxes are suitable. These should be made of a convenient size for lifting and shifting; 2½ feet long, 18 inches wide, and 3 or 4 inches deep are the dimensions of a suitable box. Six or eight holes an inch wide must be made in the bottom to allow the water to pass from the roots.

Variegated-leaved Geraniums are very subject to damp during the winter, and when there are a large number of them together it generally aggravates the injury; therefore it is often the best plan to put the variegated cuttings into pots—7-inch and 8-inch pots are suitable. From twelve to twenty cuttings according to size can be put into one of these. Three inches of drainage must be placed at the bottom of each pot, and above this a thin layer of moss must be placed; the soil may then be filled-in up to 1 inch from the rim, half an inch of fine sand should be laid on the top of this, and the whole well watered. Each pot must be done in this way, and a large number of them should be filled before starting to put in the cuttings. Boxes are filled in much the same way as pots, only the same depth of drainage cannot be placed in them; an inch is sufficient, and the roughest bits of the soil should be laid immediately over the crocks. Spent mushroom dung is sometimes used to put in the bottom, and it suits the purpose very well. In all cases the soil must be pressed firmly in, and the top-dressing of sand should be made perfectly smooth.

Having thus arranged, the cuttings may be taken off. This must be done carefully, always cutting away the parts that will least destroy the form of the plants and beds. Geraniums which are growing strongly and closely together generally produce many tender shoots near the ground. These are from their shaded position always tender, and although they may look as if they would make good cuttings they do not. Hardy top shoots are always superior; they are sometimes not so long, but they are surer in rooting and keep better after they are rooted. Most people know how to make a Geranium cutting, which is simply cutting through below a joint, removing the two leaves attached to it, and the two further up if necessary. A sharp knife should be used at this work. Clean cuts must always be made. A dibble a little longer and about as thick as one's middle finger should be used for making holes for the cuttings. The cuttings should not be put further than

1 inch or 1½ inch into the soil, and firming the soil about them must be observed. A box of the size given above will hold from four to five and sometimes six dozen cuttings. The whole must have a thorough watering after the cuttings are put in, and little or no more will be needed until they are rooted.

Cuttings of all kinds of Geraniums root freely in August set in the open air and freely exposed to the sun. They should remain in this position until the autumn frosts appear. Cuttings that are rooted, and kept as long as it is safe in an exposed place, are in much better condition for meeting a damp or severe winter than those rooted and coddled under glass. When it becomes necessary that they should be taken under cover it should be into some place where frost can be entirely excluded and damp expelled with a little fire heat when it is required. "Drawing," which is caused by the plants being far from the light and air, must be avoided at all times.

A few dozens of Verbenas rooted in autumn will supply hundreds of cuttings in the spring. The best way to deal with them is to put a number of cuttings in closely under a hand-light or any kind of frame, and keep them close until they are rooted. Soil the same as that used for the Geranium suits them. In case of failure the inexperienced should always put in more than are wanted. Shoots with no bloom on the points make the finest cuttings. The cuttings are made in the same way as from the Geraniums. When rooted they should be lifted and transferred to pots or pans. Ten or a dozen plants may be put into an 8-inch pot. Good drainage is indispensable to their well-being throughout the winter, and plenty of sand and leaf soil must be used amongst the rooting compost. By putting cuttings in early the plants become established after being transplanted before the short days occur. They should have a little artificial warmth in dull cold weather. They are, especially the white sorts, very subject to mildew in winter; any signs of this must be checked in time by dusting a little sulphur over the affected parts.

There are many other kinds of bedding plants that should be propagated in large or small quantities in autumn. The Variegated Alyssum is readily rooted in spring, but stock for this must be put in now. It roots in 6 or 8-inch pots filled with a mixture in which sand predominates, and set in a cold frame. That most useful white-leaved plant *Centaurea ragusina* is often shy in rooting. It roots exceedingly freely when placed singly in small thumb-pots. The cuttings are broken off with a heel from the side of the old plants, and the only dressing they receive is the cutting away closely a few of the lowermost leaves. After they are put in firmly and watered they are placed in a cold frame, and kept shut up closely until they are rooted. This takes place in about three weeks, and when once the roots begin to show at the outside of the ball they are shifted out of the thumb-pots into 3-inch pots. A light sandy mixture is always used at this potting. They require to be wintered in a dry airy place to prevent them from damping. Old plants are often kept over the winter and the cuttings taken off and rooted in spring, but this mode has no advantage over the autumn propagating. Ageratums may be increased quickly in spring, but to provide for this a quantity of cuttings must be put in now. Eighteen or twenty may be put into a 6-inch pot, in which they may remain all winter. Petunias are often most difficult to root. A few old plants should always be kept in store in case of failure. They root more freely in spring than in autumn. In the latter season they must be kept in a close somewhat moist frame until they begin to grow. *Heliotropiums* may be done in the same way.

Good and uniform plants of *Lobelia* are not often had perfectly true from seed. Cuttings should be selected from the best plants and rooted in autumn. To do this successfully they must be kept shaded and moist, and plenty of sand must be used in the soil. They are easily preserved after they are rooted in any dry atmosphere free from frost. Some of the *Tropæolums* are not easily rooted. *T. Cooperii* is one of the worst to manage. A great many more cuttings of it should always be put in than are wanted. Cuttings root more freely on a somewhat dry greenhouse shelf than in any other place, and they cannot be kept safely during the winter in a less heat than 50°.

*Coleuses* root freely at any time. A score or two of autumn-rooted cuttings will supply hundreds in spring. When kept moist they are liable to damp in winter. They may be fully exposed to the sun when rooting in a frame. *Alternantheras* should all be rooted now. This can be done with far less trouble at the present time than in spring. About a dozen

cuttings may be put into a 5-inch pot. They must be kept in a close frame or some other such place while rooting. They should remain in the cutting-pots until spring. If well rooted not a single one of them will die in a greenhouse temperature throughout the winter.

Where they thrive well *Calceolarias* are still exceedingly useful flower-garden plants, and nothing is more easily managed in the cutting state. The last week of September is early enough to begin with them. Any kind of frame is suitable for them. They require no artificial heat at any time. The frame in which they are put should contain a depth of 6 inches of sandy loam. A layer of pure sand is sometimes placed over the top of this, but if airing is well attended to in winter and spring so as to prevent damping this is not needed. There is never any scarcity of *Calceolaria* cuttings. They should be from 2 to 3 inches long, and they should be put in about the same width from each other. If sashes are at hand they may be laid on while they are rooting, otherwise they often do well exposed.

Pansies and Violas, now so justly popular for flower-garden decoration, will root anywhere. They need not even have frame protection. The shelter of a wall suits them as well. They should be made in the same way and about the same time as the *Calceolarias*. They must have a lighter and more sandy soil than the latter. When they are put in 3 inches apart it is not necessary to remove or transplant them until they are shifted into their final resting place. All cuttings are made in much the same way.

Where there are plenty of houses to hold them throughout the winter a large stock of everything should be rooted in a utumn, as this can be done now with much less trouble and expense than when much fire heat has to be employed in the early spring months.—J. MUIR.

#### PAUL VERDIER ROSE.

I wish to call attention to a Rose which is not often seen in exhibition stands, probably because its flowers do not expand so early as other good varieties. This trait in its character makes it of great value to me, for now that other Roses are nearly over Paul Verdier is at its best, and I am inclined to think it furnishes more perfect blooms than any other Rose I am acquainted with. It is a good deal like Beauty of Waltham in form; it is of a lighter shade than that beautiful Rose, and I think keeps its colour longer. The present hot weather scorches a few of its petals, but still I could pick fifty or sixty blooms which would not disgrace an exhibition stage. It is not, however, as an exhibition Rose that I recommend it, though a few plants of it might sometimes be found useful in making-up a collection for a late show, but as a garden Rose and a Rose for cutting when most other Roses are over I have not at present seen anything to beat it. It is a vigorous grower and free bloomer, and with me on clayey soil is best on its own roots.—WILLIAM TAYLOR.

#### IVY HEDGES.

ATTENTION has been directed to the several decorative purposes to which Ivy is adaptable, and for the various uses named on page 66 it cannot be over-estimated. It may be useful to supplement the remarks of "J." by noticing that Ivy in some parts of Belgium is used for hedges—for forming divisional lines in nurseries and as boundary fences. It is thus employed because of its hardiness, its evergreen and ornamental character, and on account of the small space which the hedges occupy. More particularly I noticed the use of Ivy for the purpose named in the interesting nursery of Mr. Charles Van Geert at Calmpthout, a few miles distant from Antwerp. In this nursery, which will be more fully alluded to on a future occasion, there are many kinds of hedges, and amongst them hedges of Ivy. These are formed in the first instance of galvanised wire netting affixed to stout and durable supports. This forms the framework of the hedge. The Ivy speedily covers the wire, and a thin, dense, durable hedge is provided. Thus without the aid of walls many of the ornamental Ivies may be cultivated in a manner not only attractive but useful, hedges formed in this way being firm and substantial.

In the same way Ivy may be trained to cover summer houses in gardens, and of which Mr. Van Geert's nursery at Antwerp affords an example. A skeleton framework—either octagonal or hexagonal—had been fixed, and the sides formed as it were

walls, also a roof, of wire netting. These were covered with Ivy, producing a cool agreeable shelter. This is an inexpensive structure, yet lasting and appropriate to many grounds and gardens. It is noticeable that where the wire had been covered with mats—ordinary Russian garden mats—previously to planting the Ivy, that the latter grew more satisfactorily, forming a quicker and a better screen than when the wire alone constituted the surface for the Ivy to cling to. These mats appear to be particularly suitable for the support of Ivy, the shoots clinging to them with great tenacity, in fact, as Mr. Van Geert observed, "eating them," so that in a very few years not a vestige of the mats is to be found. That, however, is due to the desiccating influence of the weather as much as to the gormandising power of the plant. After "eating" through the mats the Ivy becomes affixed in the wires, and is not displaced by wind, and the walls are permanent and evergreen. The Ivy only requires clipping occasionally to keep it "snug," and then no one can tell without a close examination that it is not growing on stone or brick walls. The adaptability of Ivy for these modes of shelter and ornamentation renders these examples worthy of being recorded.—J. W.

#### AN AFTERNOON AT CHESHUNT.

I HAD been so often invited by Mr. George Paul to pay him a visit while his Roses were in bloom that I determined one day to go down to Cheshunt. The afternoon was fearfully hot, and the Great Eastern railway arrangements are none of the best. It is only thirteen miles to Cheshunt, and yet we were an hour going down and nearly two hours coming back; but as soon as I reached the Cheshunt railway station I was all right, for on the platform I beheld my host, and from that moment all was jolly. He had a little pony trap waiting, constructed by a clever man who lives near his nursery, so as to traverse all the narrow roads and turns in his numerous nurseries. We drove from one to the other, getting out whenever we came to a patch of Roses and leaving the pony to the charge of another rosarian, Georgius Paulus tertius. I was much struck with the condition of the nurseries. Except in one piece of fruit trees, which had been from press of work a little neglected, no trace of a weed was to be seen. All the soil, too, was open, bearing marks of the hoe, showing how recently the men had been over it. Mr. Paul's system is to have the hoe constantly at work, so as to make the soil porous and open that the rain and dew may enter the easier. He does very little, if anything, in the way of mulching or top-dressing; his idea is to have the ground constantly moved. Certainly his plan is most economical, and most successful if results are to be taken as proofs. No one has been so uniformly successful in exhibiting Roses as he has been. If you take one year with another you will find that he is *facile princeps*. One year the seedling Briar may astonish the Rose world, at another, as this year, the Colchester grower may electrify us; but year by year Paul & Son of Cheshunt are grand. They may not be first for seventy-two, but there is never a show that they do not get one first, whilst running well for second in the others. They may at times be beaten, but they are never disgraced. They always show whatever their form may be. To the halls of crystal or to the tented field they come. Mr. Paul, ever genial, ever pleasant, ever cordial, and one of the kind-hearted men who never complain of a judge. Long may he live and flourish, long may he come up to the metropolitan shows with boxes full of blooms, which always command admiration and are generally superb. Long may he be spared to send out Cheshunt-raised Roses, and give us seedlings from the Duke, children of Charles Lefebvre, and Cheshunt Hybrids. All rosarians must feel that they owe a debt of gratitude which they never can repay to him who gave us Reynolds Hole.

And now this year he offers those beautiful seedlings concerning which I have a few words to say. I saw rows of these Roses some three years old, for Mr. George Paul never sends out a Rose which he has not proved for that term. He tries the seedling in every possible way before he advertises it, and any one, however beautiful it may be, which is deficient in the all-important quality of vigorous growth, he discards it. I saw a Rose which was a rather light Alfred Colomb or a Madame Caillat, which appeared to me to be a most promising seedling, but "Pretty is it not? but no good, there is no growth," was my host's verdict, so it is condemned. The three novelties are Duke of Connaught, Dr. Hooker, and Sultan of Zanzibar.

All these are good, particularly the first of the three. I am aware that I am incurring frightful responsibility in publicly recommending a new Rose, but I do not hesitate to do so, for I feel confident that the Duke of Connaught is a grand Rose. It cannot be better described than by saying that it is a Lord Macaulay with a good constitution.

Dr. Hooker is a rather light but a very double Duke of Edinburgh, with the additional advantage that it is a good autumnal bloomer.

The Sultan of Zanzibar was a little past its best, but Mr. Paul has shown it remarkably fine this season. It is like the original, a dark well-formed Rose after Prince Camille de Rohan, and I believe it to be a gem of the first water.

Empress of India and John Bright—please notice the delightful alliance—are two seedlings sent out through Messrs. Paul & Son by Mr. Laxton. The former is perhaps a little too like Reynolds Hole. The latter is a rich vermilion in colour, but too thin in form and weak in constitution ever to become a grand show Rose.

And now I have gone through Mr. Paul's novelties, but before I conclude I must notice the new French Rose Comtesse de Serenyi. This is a splendid light Rose, and one which will take a high position when better known.

Mr. Paul showed me a new Tea Rose garden he has recently constructed. I am afraid I cannot well give a description of it without sending a drawing, and this I am unable to do. I may say the same here as I did in the school at Oxford. I was requested to draw a map of Sicily, so I took out a half-crown from my pocket, made a circle, stuck Pergamos in the middle, and took it up. "What!" said the examiner, "this a map of Sicily?" "Please, sir, I was never taught drawing when I was a boy." This so tickled the good men that they were unable to continue for some little time, and I got through. But the Tea-Rose-garden system is one which I think will be most successful. It consists of cordons nailed against upright posts up which the climbers are to grow, the whole being covered in by hurdles or mats; the beds underneath being planted with dwarf Teas on the seedling Briar. The idea is to protect in winter and retard in spring and early summer. The result is yet to be seen.

I was most hospitably entertained, and had a little difficulty in getting away—in fact I had to run for a quarter of a mile or so in order to catch the train, but I did catch it, and had plenty of opportunity of cooling, for the Great Eastern most kindly kept the train waiting twenty minutes outside the Liverpool Street station and I did not get home till midnight; but I had a most pleasant visit, and would recommend all rosarians who want to see growth and blooms to visit Cheshunt in the Rose season.—JOHN B. M. CAMM.

## ROYAL HORTICULTURAL SOCIETY.

AUGUST 1ST.

A MEETING of the debenture-holders of the Royal Horticultural Society was held at noon last Tuesday, in the Council Room of the Society, South Kensington, "to receive a statement from the President (Lord Aberdare), as to the financial position of the Society." At the Council-table were Lord Aberdare (in the chair), Lord Alfred Churchill, Mr. Henry Webb (Treasurer), Dr. Hogg (Secretary), Mr. Kellock, Dr. Denny, Mr. Haughton, and Major Mason. Amongst the debenture-holders were General Mackinnon, Admiral Sir Edward Belcher, Capt. Derriman, Admiral Boyle, Dr. A. Fyfe, Mr. Edgar Bowring, C.B., Lieut.-Col. D. Labalmondiere, Mr. J. J. Loundes, Mr. W. H. Solly, Mr. George Reay, Dr. Martyn, Mr. A. E. Adamson, Mr. David Robinson, &c. There were some ladies present.

The PRESIDENT rose and said—Ladies and Gentlemen, we are met together to-day in accordance with a notice which no doubt you have received from the Royal Horticultural Society, and the object of our meeting is to give you, the debenture-holders of the Society, the first possible opportunity of considering what your position is with respect to the Society, what it is you possess in point of security for the repayment of your interest and ultimately of the principal of your debentures. We have called you together at this moment, and we really wish it were in our power to have called you together at an earlier date, but the fact is we have been so deeply and constantly engaged considering the position and affairs of the Society, that it is only at this very last moment we are able to place before you anything like a definite statement of your position. This is the more due to the debenture-holders, who, after all, are the people who are chiefly pecuniarily interested in the prosperity of the Society, because I find that even amongst the holders of these debentures of the Royal Horticultural Society there exists a very vague and extremely inaccurate idea as to what was the security

given for their money when they became possessed of these debentures. Well, ladies and gentlemen, I will state to you as briefly and as concisely as I can what, in the belief and opinion of the Council the exact nature of the security of the debenture-holders is—first as to interest, and then as to the capital itself [hear]. By two agreements entered into—one in July, 1860, the other in March, 1861, between the Exhibition Commissioners of 1851 and the Royal Horticultural Society, power was taken to raise £50,000 upon debentures of the Society. The Royal Horticultural Society was to raise the money in this manner—In the first place, all the receipts of the Royal Horticultural Society were to be applied to the maintenance of the gardens—that is to say, their maintenance in a fit and proper condition, and to the promotion of their shows: in fact, to the performance and execution of their business as a horticultural society; and then it was provided that if there should be any surplus from the receipts, that surplus should be applicable, in the first place to the payment of the debenture-holders' interest, in the next place to the payment of rent to the Exhibition Commissioners of 1851, and especially that if any surplus remained after providing for the items I have mentioned, three-fifths of the same should be applied towards paying off the actual capital of the debenture-holders. Now, with respect to the debenture-holders' interest, interest has been paid till very recently by the Society, but I regret to have to state that at least £5000 of the interest has been improperly paid to the debenture-holders. Here I may be permitted to say that the Council and the Society are most anxious that the debenture-holders should not in the least degree suffer, especially from the payment to them of a sum of money not properly applicable to the discharge of the interest on their debentures. Let the debenture-holders bear in mind that the duty of the Royal Horticultural Society was, first of all, to provide for all their ordinary payments, for all their expenses and debts incurred for the keeping and maintenance of the gardens. That simply was the first and paramount duty of the Society. When I joined the Society I found that a debt of something like £5000 had been incurred by the Society, practically incurred by the payment to the debenture-holders of money, of sums of money which were only applicable to the payment of the expenses of the Society, and it was only by an arrangement entered into with the Royal Commissioners that we were enabled to raise upon their security the sum of £5000, which has been applied to the discharge of the debts so incurred by the Society, which debts should have been cleared off by the amount paid to the debenture-holders. With respect to the security for the capital of the debenture-holders, it consists of two sorts: First, as I have already mentioned, in the event of there being a surplus after providing for all the proper expenses of the Society, for the payment of the debenture interest, and payment of rent to the Royal Commissioners—if, after all these being provided for, there still existed a surplus, three-fifths of it was to be applied towards the diminution of the debenture debt. I can only find in one year any such sum as would do all that, and that was the first year of the Society's operations—in 1863—and in that year the sum of £300 was found to be applicable to this purpose, and accordingly £300 of the debenture debt was extinguished. Since that time I am sorry to say the Society has had no surplus, and in fact the receipts of the Society in most of the years since that time have been insufficient to pay the rent to the Royal Commissioners. It is clear, therefore, that that security has failed in respect of the debenture-holders. But then there is another contingent security, which is this: By the agreement of 1860 the Commissioners leased these gardens for thirty-one years to the Society at a rental of £2145 on certain conditions. If, at the end of these thirty-one years—in the year 1892—the Society fulfilled all the conditions to which it subscribed, and amongst these conditions paid the rent agreed upon and due to the Royal Commissioners, it would then be in a position to ask for a renewal of the lease, and if the Royal Commissioners declined to grant that renewal they would be obliged to pay one-half the debenture-holders' debt. But I am sorry we have not been able to pay the rent to the Royal Commissioners, and I am more sorry to say there is very little hope of our being able to do so. You are all, no doubt, aware that the Royal Commissioners granted us what may be called three years of grace, binding us to raise the sum of £7000 applicable to the payment of our debts and relieving us from the payment of rent for the gardens for three years on the condition that during the three years we should exert ourselves to raise the subscriptions of the Society to the amount of £10,000 annually. Well, we have made the very best exertions we could make, we have honestly done all we could do; but I am sorry to say the result—partly, perhaps from the nature of the case, and partly from the fact of three years' bad business—did not bring us in the amount of subscriptions which would enable us to carry on the gardens, having raised the subscriptions to the sum of £10,000 a-year, the amount the Royal Commissioners stipulated for. Taking everything into account, the actual amount of our subscriptions can only be looked at as £4500; and then on the other side, including rates and taxes and the payment of the debenture-holders' interest, our expenditure comes

up to £8500 a year, so that it is obvious we are not in a position to carry on the gardens even to the end of the year at that rate of expenditure. Not only the present Council but that which preceded it have honestly and earnestly exerted themselves to reduce the expenditure of the Society. I am not aware that any material or sensible reduction can be made beyond the point we have reached. It seems to me, therefore, it will be the bounden duty of the Society to put an end to their existence until such time as they can start on a new basis. In doing so it is impossible they can pay the debenture-holders their interest until the surplus receipts are obtained; and, such being the case, we thought it our duty to the debenture-holders to lay the facts of the case before them, so that they should take such measures as they may think best calculated to secure their interests [hear, hear]. I have now submitted all the facts which it was necessary to bring under your notice, and I only trust I may at some future time be able to make a more cheerful and satisfactory statement [hear, hear].

**A DEBENTURE-HOLDER.**—In case of the winding-up of the Society, have the bondholders any claim on the existing buildings? That is a question I should like his lordship to answer.

**THE PRESIDENT.**—None whatever. I do not know that the Society can be wound up. It exists under a charter. I may say we are most anxious to keep out of debt, and we are out of debt, but not in a position to go on.

**THE DEBENTURE-HOLDER.**—In any case, no matter how things go, we have a right to get our interest on our debentures.

**THE PRESIDENT.**—The debt to the debenture-holders only arises when certain surplus receipts arise. The debenture-holders are really in debt to the Society, and not the Society in debt to the debenture-holders [laughter], because interest to the amount of £5000 was improperly given to them ["oh!"] It was only by a subsequent arrangement with the Royal Commissioners that we were enabled to pay off that debt of £5000. In this way you will see the debenture-holders have received in reality £5000 more than they ought to have received.

**THE DEBENTURE-HOLDER.**—The debentures having been issued by the Society, and interest having been paid on these debentures up to February last, we consider the Royal Horticultural Society is indebted to the debenture-holders [hear, hear].

**MR. GEORGE REAY.**—We look to Her Majesty's Commissioners, for they are the people who borrowed the money. They borrowed the money, and we look to them to refund it [hear, hear]. If they do not refund our money we consider that our money has been taken away in a very improper manner.

**THE PRESIDENT.**—Some of our negotiations with the Royal Commissioners were not successful.

**MR. REAY.**—But all the time the Royal Commissioners used our property [hear, hear]. The Council of the Royal Horticultural Society and the Royal Commissioners seem to have been entirely engaged making their own arrangements between themselves; but no one ever consulted us as to the payment of our debt, and I do not believe the Council of the Royal Horticultural Society or Her Majesty's Commissioners, in any arrangements made between them in reference to the business of the Society or the relations between the two bodies, ever bestowed one thought upon the debenture-holders. It is my opinion, and I believe—at least I have no doubt—it is the opinion of many, if not all the debenture-holders in this room, that they have been most improperly treated both by the Royal Horticultural Society and Her Majesty's Commissioners [hear, hear].

**THE PRESIDENT.**—By the arrangements—for which I am not responsible—which the Society made with the Commissioners the receipts taken by the former enabled them to pay interest to the debenture-holders which they otherwise would not have been enabled to pay. In considering this question that fact ought not to be lost sight of. Again, the receipts on these former years did not enable the Society to reduce the capital, but simply to pay the interest.

**Admiral Sir EDWARD BELCHER** was understood to ask, as the oldest member of the Society, a question of the President respecting the meeting of the Fellows.

**THE PRESIDENT** said there would be a meeting of the Fellows of the Society on Wednesday, at which all matters referring to its condition and prosperity could be discussed. If anyone had anything in opposition to the Council to say, he could say it.

**Admiral Sir E. BELCHER.**—I address the meeting as the oldest member of the Society, and I will try and induce those who are here to-day to come to the meeting of the Fellows to-morrow.

**THE PRESIDENT.**—But you will perceive that—

**Admiral Sir E. BELCHER.**—Allow me to address the meeting and answer me afterwards.

**THE PRESIDENT.**—You address the meeting as the oldest member of the Society—

**Admiral Sir E. BELCHER.**—I have not begun my argument. When I have finished it you can answer me.

**THE PRESIDENT.**—I am Chairman here, and am very anxious to give to everyone the fullest opportunity of expressing his views, but it is my duty to see that the discussion at this meeting is rightly and properly conducted. We are not here to-day

to discuss the affairs of the Royal Horticultural Society, but the interests of the debenture-holders [hear, hear]. If the gentleman will keep himself to the question of his own interests as a debenture-holder he will be in order.

**Admiral Sir E. BELCHER.**—When I purchased my debentures the interest on them was at the rate of 5 per cent., and afterwards, most dishonourably, the administrators of this Society withdrew 1 per cent. without consulting the shareholders generally. When you did that you kept it back from the debenture-holders, and you never told us where that money was to come from. You borrowed the money from us at 5 per cent., and then held it at 4 per cent. I entreat debenture-holders not to trust to the dictum of any man, but to go to the Court of Chancery and have their rights enforced [no.] If the meeting is of the same opinion as I am, I am willing to sacrifice every farthing I have to bring to light the dishonourable conduct of the Society in this matter.

**THE PRESIDENT.**—It is a great pity we should have these hard and harsh expressions used [hear, hear]. What has been stated is not a fact—at least so I am told; and, after all, it is not a question of law, but one of fact. It is not a fact that the debenture-holders were not called together with respect to the reduction of their interest. I am told they were, and that they consented to the proposal upon the principle of being better to receive half a loaf than no bread. As to information, every debenture-holder has the information on the back of his debenture. I had to read it myself, and it is not the most agreeable literature, and I find on the back of every debenture what, as to security, is in reality the substance of what is to be found in the original agreements of 1860 and 1861, both of which are printed on the back of the debenture. I know people do not sometimes read these things very carefully, but a man putting his debenture into a lawyer's hands would just get the same information which I have given you.

**MR. REAY.**—They agreed to pay us 4 per cent. on our debentures.

**A DEBENTURE-HOLDER.**—We knew nothing about the security. How were we to know what security we were getting for our money?

**THE PRESIDENT.**—Of that I know nothing. When people lend their money they usually look after the security they are getting. The security would be learned from a copy of the debenture put into my hands.

**THE DEBENTURE-HOLDER.**—But there must have been some inducement or some good security to get people to take up these debentures.

**Admiral Sir E. BELCHER.**—All I can say is, I advise my friends to join together and obtain legal advice and authority to enforce their claims—their honest claims.

**A DEBENTURE-HOLDER.**—What security did they offer for the money paid on the debentures?

**THE PRESIDENT.**—I am not exactly able to speak as to that.

**THE DEBENTURE-HOLDER.**—But the Council ought to be able to speak upon the subject.

**THE PRESIDENT.**—You have your debenture.

**Another DEBENTURE-HOLDER.**—It is easily surmised what the inducement was.

**A third DEBENTURE-HOLDER.**—It was the 5 per cent. [hear, and a laugh].

**MR. REAY.**—I imagine we all thought we would get good security for our money. I am sure a great many of us in giving our money relied entirely upon the good name of those connected with the Society [hear, hear]. Can your lordship tell us how the matter stood when the debentures were taken up?

**THE PRESIDENT.**—I cannot tell exactly what took place on that occasion.

**A DEBENTURE-HOLDER.**—Were the accounts audited and sent to the debenture-holders at the end of each year?

**THE PRESIDENT.**—I believe every debenture-holder, like every Fellow, had a copy of the accounts.

**THE DEBENTURE-HOLDER.**—Because it seems to me it has not transpired until the eleventh hour, when the Society is in point of fact regularly gone down, that this £5000 referred to by his lordship was improperly treated. This is in fact the old story of paying interest out of capital.

**THE PRESIDENT.**—The Council paid the debts of the Society with the money they raised. As to the debenture-holders not receiving copies of the accounts, I really cannot say anything at all about that.

**DR. MARTYN.**—As it has been truly said, we really relied upon the good repute of the Commissioners and the Society for dealing with us in a fair and liberal manner. To advance money at 4 per cent. and run all the risk would be a terrible position to place us in. We are placed in that position by the Commissioners or the Society. The busy life I have led has prevented me looking into the matter. In all speculations a man must look after his own affairs, and what is now before us shows how little you can rely upon Royal Commissioners or anyone else [hear, hear]. I have always relied upon some consideration on the part of the Commissioners, who are a body of wealth and

power, and men sure I should think to see we are not losers. I do hope the Royal Horticultural Society and the Commissioners are bound in honour to see we are not let into the loss that seems to be contemplated by this meeting. The taking of 4 per cent. and the risk as to the security is too bad, and we ought to be helped by the responsible parties out of our position [hear, hear].

The PRESIDENT.—If the debenture-holders like to address themselves to the Royal Commissioners, it is for them to see in what form they will approach them. I do say on the part of the Society, it has not the means to do more than discharge its existing engagements—to carry on the gardens to the end of the year, and that with the strictest economy. I may say I have got in my hand a notice given to the debenture-holders of the reduction of the rate of interest.

Dr. MARTYN.—That is perfectly right.

The PRESIDENT.—I will read the original, signed "John Lindley, Secretary," and dated the 8th July, 1859. The noble lord then read the original document, which stated that at the desire of the Council a special meeting had been held the previous day with respect to acquiring twenty acres of ground on the condition that the Commissioners would surround the gardens with beautiful Italian arcades, and do other extensive works at a cost of £50,000, giving to the Royal Horticultural Society a lease of thirty-one years, who were to construct a suitable garden. Then the document dealt with the surplus, which was afterwards modified to the extent that two-fifths were to go to the Royal Commissioners and three-fifths to the debenture-holders. After that the noble President read a resolution of 31st July, 1861, in which it was stated that the rate of interest given to the debenture-holders having been brought under the notice of the Council by some Fellows of the Society, who were of opinion that money could be got at 4 per cent., it had been urged on them to pay off those not willing to take 4 per cent. The Council had come to the conclusion that the most equitable thing was to lay the matter before the debenture-holders, and leave it at their option either to hold their debentures at 4 per cent. or be paid off. It appears, said the President, then, that an assent had been given to that in 1861, and the payment accordingly had been made; but at that time the prospects of the Society were much more flourishing than they now are. Next year a sum was realised not only sufficient to meet the expenses of the gardens, but also to provide a sum for paying off the debenture-holders, and so in the following year the sum of £300 was so applied. I have no doubt, as no one can have any doubt, that the condition of the Society at that time made investors less careful in looking to the nature of the security of their investments than they would have been now [hear, hear].

A DEBENTURE-HOLDER.—With all this talk I should like to know whether your rent has ever been paid.

The PRESIDENT.—The full rent has been twice paid, and for other terms only a portion of the rent has been paid.

The same DEBENTURE-HOLDER.—Then I believe you have had no paying business at all.

The PRESIDENT.—Oh, yes; the debenture-holders had the first claim for interest, then came the claim for rent, and then and lastly the claim for the capital of the debenture-holders. I may say, however, that you debenture-holders have received £30,000 in interest.

A DEBENTURE-HOLDER.—But you have never had anything to pay or to spare.

The PRESIDENT.—I beg your pardon. In one year there was enough money to pay for all the three claims I have enumerated, and in addition to that the Society put aside £300 to be taken off capital.

A DEBENTURE-HOLDER.—How was the agreement carried out?

The PRESIDENT.—The terms of agreement were these:—First, to provide for the necessary expenditure to keep up the gardens at Chiswick and South Kensington; next, to the payment of the interest on the debenture debt; and after that payment on the £50,000 borrowed by the Commissioners. Summarised it is this—First, payment for expenditure on the maintenance of the gardens; secondly, the interest on the money borrowed by the Royal Horticultural Society; and next the money of the Royal Commissioners.

Admiral Sir E. BELCHER.—I would remark upon what are called the "necessary expenses" of the gardens. I maintain that the accounts rendered have been unjustly and dishonestly given to us, because we have in these accounts a number of items of expenditure with which we have nothing to do as far as the maintenance of the gardens is concerned. I am a Fellow who took this business up with Mr. Freake. I was not sorry when I did so, because he talked of 20 per cent. for our money [laughter], and said if the Prince Consort would only join in the affair we should be well started. Well, we waited a week or so, and then I went with Sir Wentworth Dilke, and we both got an introduction to the Prince. We could have made a profit of it—at least we thought so, because we calculated that, honestly, care would be taken that no other expenses than those necessary would be incurred, and not other expenses paid in preference to

honest ones. Now, my lord, I belong to the Royal Horticultural Society, but I belong to the Royal Navy also, and if I in the Royal Navy had acted as you have done—so scandalously—with our money, I should have been turned out of the service [cries of "oh, oh!"]

The PRESIDENT.—The sooner you, sir, leave this room the better [cheers]. You are not talking as a gentleman, because you are speaking to me personally who have nothing whatever to do with the matter.

Admiral Sir E. BELCHER.—I say your conduct has been most discreditable and dishonourable [no, no].

The PRESIDENT.—All I can say is, that you are now acting in a way discreditable and disgraceful to the noble service to which you belong [loud cheers]. We are here to discuss the questions affecting the debenture-holders, for whom I have a most profound sympathy. It is impossible not to be sorry that the debenture-holders are sufferers in the way they are [hear, hear]. But I may remark this, that we can gain nothing and may lose much by the use of this irritating and insulting language which, I regret to say, has been used, unnecessarily as I think, upon this occasion [hear, hear].

A DEBENTURE-HOLDER.—I should like to ask the noble Chairman whether it is the intention of the Council of the Royal Horticultural Society to surrender the lease of the gardens to the Commissioners?

The PRESIDENT.—They cannot do that without the consent of the debenture-holders. We have taken legal advice upon this point, but I believe if the debenture-holders wished to make some arrangement with the Royal Commissioners all parties would be glad indeed.

Mr. J. J. LOUNDES.—I should like to ask, Is there any value at present for what has been laid out upon the gardens?

The PRESIDENT.—That would depend very much upon the use made of the gardens.

Mr. E. BOWRING wished to say a word or two about that simple matter of the three-fifths being paid to the debenture-holders and two-fifths to the Royal Commissioners; but this two-fifths went to the Society exclusively. Mr. Bowring went on to say that it was not a fair or a true statement to say that the money was laid out in waste by the Royal Commissioners.

The PRESIDENT.—What I said was that the Commissioners did spend money.

Mr. BOWRING.—Yes, the Commissioners spent £60,000 or £70,000, and the Commissioners built arcades, the Society laid out the gardens and the Commissioners made the necessary outlay. He should like to say a word on the circular which he was glad the Chairman had produced and read. He had the clearest possible recollection of having received that circular. The reason the interest was brought down to 4 per cent. was that the prospects of the gardens were extremely good. The Prince Consort was alive at the time, and everything in connection with the gardens looked well. Besides that the debenture-holders received two guineas in the shape of admission to the gardens. They had a personal admission, or could send anyone they wished in their place. They got in point of fact £7 2s., and even when that was reduced to £6 2s. it was not bad interest to get. In addition to that the debenture-holders were informed that their debentures should take precedence of every other claim after the maintenance of the gardens. At the time referred to it was a good investment to take a debenture of the Society. Another point of importance was this—that all through the agreements "rent" was spoken of, but they must all bear in mind that with the exception of one year the Commissioners never received rent from the Society. It was quite true the word "rent" was used, but it was used only as a lawyer's phrase; but what was really "rent" was the interest on the money which the Commissioners themselves had to borrow at 4 per cent. to lay out and start the gardens. The Commissioners spent £50,000, the Society agreed to spend £50,000, and there was, say, that much raised on debentures.

The PRESIDENT.—The total spent by the Society was £73,000, and the total spent by the Royal Commissioners was £63,000.

Mr. BOWRING.—My point is that our claim as held on these gardens ranks next to the working expenses, and not one single farthing of the £60,000 could be received until you paid us our claim. That has been our legal position. I now come to a much more important point. The noble Chairman has told us we have been paid £5000 improperly. Ladies and gentlemen, as ladies are unfortunately debenture-holders as well as men, when £2000 a year has to be paid to the debenture-holders, any statement with respect to £5000 being paid would represent the interest for two and a half years not paid to us, and that would take us back to the second half of 1873. That second half of 1873 was during the unfortunate dissensions in the Society which commenced early in 1873, and therefore I think we can trace the non-payment of our interest to the unfortunate state of the Society at that period [cries of "hear"]. Had the debenture-holders voted on that occasion, when the whole of the Council were turned out, and when the South Kensington interest took the supremacy, I believe the disaster would not have taken

place. I hold in my hand a paragraph I saw in the *Morning Post* some day last week, and which, to my mind, seems to have been inspired. It says, "The position of the Society is this: It is not in debt, is paying its way, but in want of capital for carrying on its operations. To the debenture-holders £50,000 is due, but they have received in interest at 4 per cent. £30,000 in all." Well, that looks as if we having received the £30,000 should not be very much dissatisfied if we have to put up with a total loss of our money [a laugh].

The PRESIDENT.—I must say I never saw the article myself.

Mr. BOWRING.—Then we have a significant article in the *Journal of Horticulture*. Ladies and gentlemen, it is no secret who the Editors of the *Journal of Horticulture* are. Their names are printed on the front page of the paper, and one of them (Dr. Hogg) is an active and prominent member on the Council. Here, now, in the *Journal of Horticulture* of July 27th is the following very serious statement with respect to the payment of interest on the debenture bonds: "The only fault that can be charged against past Councils is that they should have paid interest on the debenture bonds when a profit had not been made. The interest on these is payable out of the surplus receipts from the gardens, and as it is well known that there has not been, except in two or three years, any surplus receipts from the gardens, the payment of debenture interest was manifestly most culpable. This has, no doubt, been the reason why the Society has been so crippled all along. An annual payment of £1950 for interest alone which was not due would ruin any concern. Happily the present Council have acted more justly towards the Society, and the payment of the interest is stopped." Now, I hold that this is a most curious statement to be made. People have been paid their interest for the last sixteen years, and, indeed, because that is the case we ought to be well content with our present position. Although it is not my business to go against the Society, we ought, as to a statement of fact, have our minds made clear, because if we think the Society has most culpably paid us our interest we ought not to be very happy in our minds. It was my lot in 1863 to act as Honorary Secretary to the Expenses Committee, and that Committee had always laid before them an accurate statement of receipts and expenditure, and also as accurate an estimate as could be possibly made of the receipts and expenditure of the forthcoming year. Upon that statement as to the past and the future was regulated the amount which was to be laid out on the Society as a first charge—namely, the expenses of the gardens. I may state as a positive fact that in former times when I acted as Honorary Secretary, in no single year did the Expenses Committee allow any sum to go for the expenses requisite for the maintenance of the gardens until they satisfied themselves there was a sufficient sum to pay the debenture-holders.

The PRESIDENT.—Were you bound to do that?

Mr. BOWRING.—Not bound; but there always was a sufficient sum in those days to pay them.

The PRESIDENT.—But you put it that the expenses for the maintenance of the gardens had the prior claim.

Mr. BOWRING.—In addition to all that, you must remember we had before us the estimate of the year.

The PRESIDENT.—Then it was spread over a longer period.

Mr. BOWRING.—At all events the minutes of the meetings show that up to the last three or four or even five years the interest was honestly and fully earned, and therefore, to the statement that it was improperly laid out, that I think is a sufficient answer. In conclusion of my remarks I would express a hope that some practical proposal will be made [cries of "hear"]. I think we ought to bring our deliberations to some practical and sensible conclusion. It would in my opinion be very desirable that a small committee of debenture-holders should be appointed to confer with the Royal Commissioners and the Council of the Society, because it is clearly our interest and our duty to place ourselves in communication with them. I am in great hopes that someone will make some such proposal. I may add that three or four years ago the Commissioners made a proposal to the Society which I think the debenture-holders would have received very favourably.

Admiral Sir E. BELCHER.—It does not appear from what I can learn that the debenture-holders are to be present at the special general meeting of the Society to-morrow to represent at that meeting our interests. I should like to know whether at to-morrow's meeting the debenture-holders can come in and vote with the rest?

The PRESIDENT.—Certainly not.

Admiral Sir E. BELCHER.—Then it will be all on one side. If people vote that the debentures be not paid, the voting will be all one side.

Dr. MARTYN.—I may say I have felt it a very great grievance that we have not been admitted to the consideration of all the financial matters connected with the Society. The horticultural matters of the Society are all very well in the hands of the Society itself, but that all the accounts should be arranged and settled without the knowledge of the debenture-holders appears

to me to be a great hardship. I once more refer to the inducement we had to enter the Society. It was because the security was thought to be so good that the reduction in the interest was proposed. I relied entirely upon the *bona fides* of those who had the management of the affair, and possibly the result of this meeting and of the meeting to-morrow will be that the Royal Horticultural Society will come to a dissolution. In that case I should like to know upon whom, if upon anyone, we shall have a lien—that is, on the property in the gardens. Debenture-holders, as a general rule, have always a lien on some sort of substantial property [hear, hear]. I should propose that we put ourselves in communication with Her Majesty's Commissioners and hear from them what terms they are likely to give us, or rather what terms we may look for [hear, hear]. I am not acquainted well enough with the internal affairs of the Society to be able to know whether it is the intention of the Council of the Royal Horticultural Society to bring this Society to a close; and while I am upon that point I would also ask whether, inasmuch as Chiswick gardens are connected with this Society, we have not, in respect to our debt, a lien upon them.

The PRESIDENT.—I think the observations of the last speaker are very well worthy of attention; but I would point out this, that if a committee of debenture-holders is appointed the committee themselves would undoubtedly look into their legal position as to a lien upon the property of the Society, either upon its property here in South Kensington or its property in Chiswick gardens. There will be a great advantage in doing that—indeed far greater than in hazarding legal opinions here which may be all reversed [applause].

Dr. MARTYN.—Then, my lord, I will propose a resolution.

The PRESIDENT.—A resolution has just been put into my hand.

Dr. MARTYN.—Well, probably it anticipates mine.

The PRESIDENT.—At all events I think it is a resolution which will meet the necessities of the occasion.

Mr. G. REAY.—Well then my lord, the resolution I beg to propose is this: "That a committee of debenture-holders be appointed for the purpose of entering into communication with the Council of the Royal Horticultural Society and the Exhibition Commissioners of 1881."

Dr. MARTYN seconded the motion.

The PRESIDENT.—That is the most business-like course which could have been adopted. I should like to say that with reference to a remark made as to a possible dissolution between Chiswick and South Kensington, that is not a matter that properly comes within the limits of our discussion to-day. That is a matter which is entirely in the hands of the Fellows of the Society.

A DEBENTURE-HOLDER.—After that resolution is passed the first thing you have to do is to appoint a committee in accordance with its terms.

The CHAIRMAN put the resolution for the appointment of a committee, which was unanimously carried. His lordship then said: The next thing you have to do is to nominate your committee.

Dr. MARTYN.—Those who form the committee should be thoroughly trained in all the business and affairs of the Society [hear, hear].

The PRESIDENT wished to say, with reference to the remarks of Mr. Bowring, that he was glad to hear a gentleman of so much authority in the Society speak, but did not endorse his statement as to the mal-application of the funds being during the last three or four years. He (the President) only wished to make himself correct, and to show he had not intended to say the mal-appropriation was made within the last three or four years.

Lord ALFRED CHURCHILL.—I may be allowed to remark that we paid during the last fifteen years £30,000 interest on debenture debt. We borrowed through the authority of the Royal Commissioners £5000 to pay our past debts and expenses. Well, it is very evident that if we had not paid that £30,000 we should have been able to clear our expenses without having to borrow that £5000. As to the fact of our being called together to-day, I may state that the bye-laws do not provide for any dealing with the bondholders, but in the exceedingly critical position of the Society we felt it our duty to call you together [hear, hear], because our income is so low that in a short time the gardens would be bankrupt, and then we should be dropped into the Bankruptcy Court. We have also been advised by counsel that the Council of the Royal Horticultural Society cannot resign their lease of the gardens without the consent of the debenture-holders. Therefore it is necessary, both for the interests of the Society itself and those of the debenture-holders, that some arrangement should be made by you through your committee in order to confer with the Commissioners and endeavour to get from them as good terms as you possibly can [hear, hear]. I know it is disputed by the Commissioners and by others that the Commissioners are liable to you for 10s. in the pound, or for one-half of what is due to

you. They maintain this. The debenture-holders say, "Renew our lease." They say, "No, it is forfeited;" and then the debenture-holders will rejoin, "Well, then, pay us 10s. in the pound. You introduced the Society here. You brought the Society from Chiswick to South Kensington. You made yourselves joint partners with us; and you have also provided that under certain contingencies you are to receive an extra amount beyond what you now have." Now this, I believe, would constitute a partnership. I think you should go to the Commissioners, and say to them, "Is it not better to come to some suitable terms with us, and enable us to get out of our debts, and enable the Council of the Society to resign the lease?" These are the considerations which should occupy the committee, which should meet at an early day, and they should confer with the Commissioners as soon as possible [hear, hear].

Dr. MARTYN (to the President).—Your lordship is not a debenture-holder?

The PRESIDENT.—No.

Lord A. CHURCHILL.—But I am a debenture-holder [laughter].

The PRESIDENT.—You had better appoint a committee, with power to add to their number.

Dr. MARTYN.—I think Mr. Dick, from his intimate knowledge of the debenture-holders, knows those who are best acquainted with the business. I am to a certain extent a stranger here, and am at a loss to know who should be nominated.

The PRESIDENT.—Suppose you form a committee of seven, name three now and four afterwards. Perhaps that would do as well as any other course [hear, hear].

General Mackinnon then moved, and Mr. George Reay seconded, a resolution to the effect that a committee of seven be formed—that Mr. Reay, Dr. Martyn, and Mr. Doughty be three members of it, and that they have power to choose the remaining four members.

A cordial vote of thanks was accorded to the noble President, and then the meeting was closed.

#### SPECIAL GENERAL MEETING.

A SPECIAL general meeting of the Fellows of the Society was held yesterday afternoon to hear a statement from the President as to the financial position of the Society. In a lucid statement Lord Aberdare (the President) told the Fellows the exact position of the Society, and showed that it was impossible for the affairs of the Society to be carried on under the present expenditure. The noble Chairman placed the position of the Society before the Fellows as utterly hopeless; but, at the same time, said that the Fellows and the public ought to disembarass themselves of the idea that there was any wish on the part of the Royal Commissioners to possess themselves of the gardens. [This was received with cheers.] There followed a great deal of discussion, in which Mr. Godwin, Mr. Guedalla, Mr. Liggins, Mr. Shirley Hibberd, the Hon. C. Butler, Mr. C. Morgan, Lord Alfred Churchill, Mr. Smea, and others took part, and eventually the following resolution was passed:—"That this meeting approves of the policy of the Council in endeavouring to effect a separation of interests between the Royal Horticultural Society upon equitable terms with the debenture-holders and life Fellows, and requests the Council to urge an early settlement with Her Majesty's Commissioners." The resolution was moved by the Hon. C. S. Butler and seconded by Mr. Shirley Hibberd. A protracted meeting was brought to a close by a vote of thanks to the noble Chairman.

#### ROYAL HORTICULTURAL SOCIETY.

AUGUST 2ND.

FRUIT COMMITTEE.—H. Webb, Esq., in the chair. Three bunches of Black Hamburgh Grapes and two dishes of Nectarines (Elruge) were sent from Mr. Edmund Bland, gardener to J. G. Smith, Esq., Cranbourne Court, Winkfield. The berries of the Grapes were very large and fine. A letter of thanks was voted. A red-fleshed Melon was sent by Mr. C. Osman, South Metropolitan District Schools, Sutton, Surrey, but the flavour was inferior. Golden Nugget Melon, a green-fleshed variety, was sent by Mr. D. Davis Hughes, Kimmel Park Gardens, Abergele, but the flavour was inferior. Welbeck Seedling Nectarine was sent by Mr. W. Tillery of Welbeck Gardens. The fruit was of large size, very highly coloured, and of excellent flavour, resembling Elruge, but said to be two weeks earlier. A first-class certificate was awarded, subject to the statement about its earliness being verified. The same gardener sent excellent examples of Grosse Mignonne Peach fully ripe from a glass-covered wall, to which a letter of thanks was voted. A dish of very fine unnamed Red Currants were sent from the Society's gardens; the bunches were very long and fine.

A collection of Indian vegetables was sent by Mr. A. F. Barron from the Society's gardens. The seeds had been sent by Col. Puckle. *Amaranthus oleraceus*, the seeds of which are used to make cakes, and *Atriplex hortensis*, whereof the leaves are boiled as a vegetable. A number of other herbs were in the collection which would be of no practical use in this country.

FLORAL COMMITTEE.—Mr. B. S. Williams in the chair. The subjects brought before the Committee were somewhat more numerous than has been usual of late. Particularly noticeable was a pan sent by Messrs. James Veitch & Sons, containing eighteen small plants of *Begonia Davisii*, a dwarf Peruvian species, thoroughly distinct and extremely brilliant. The plants were small, the leaves being about 1½ inch in diameter, each plant producing one or more spikes of flowers of the most intense orange scarlet imaginable. The flowers averaged an inch in diameter, and the effect they produced was quite dazzling, the colour being very similar to that of the new prolific Poinsettia. This free-flowering and almost hardy *Begonia* will not only prove a charming decorative plant, but will be invaluable for purposes of fertilisation. A first-class certificate was unanimously awarded. Messrs. Veitch had also a first-class certificate for a new greenhouse *Rhododendron*—Maiden's Blush; a very charming variety, the flowers being blush deepening to cream colour. The foliage is of the richest green, and the plant is extremely floriferous. It well deserved the award. The same firm exhibited a very fine *Begonia*—Monarch, the flowers being large and rich in colour, and the plant vigorous; also the hardy sweetly-scented shrub *Olearea Hastii*.

A first-class certificate was awarded to Messrs. Daniel Brothers, Norwich, for *Godetia* Lady Albemarle, a remarkable and splendid variety, far superior to any other of the family. The plants are not more than 6 inches in height, and may be said to be "all flowers." The prevailing colours are crimson suffused with lilac. This is one of the most splendid of all hardy annuals. A similar award was made to Mr. Noble, Sunningdale Nursery, Bagshot, for a new Rose, Queen of Bedders, a seedling from Sir Joseph Paxton, but much richer and altogether superior to that Rose. As many as twenty-five flowers were produced on one truss, and the variety will be valuable for garden decoration.

Messrs. F. & A. Smith, Park Road, West Dulwich, sent a large collection of Balsams, the flowers being exceedingly fine, and the colours distinct and varied. It is an excellent strain, and a vote of thanks was awarded for the collection. Mr. Dean exhibited single flowers of Balsams of no particular merit. Mr. Elliott, seedsman, 139, Bradford Road, Huddersfield, exhibited a pair of Cockscombs, very dwarf and fine; a vote of thanks was awarded. A similar award was made to Mr. Newman, gardener to W. H. Michael, Esq., Highgate, for a collection of *Gloxinias*, *Rasanovias*, and *Tydeas* in very good varieties.

A vote of thanks was awarded to Mr. Tomkins, nurseryman, Shardhill, Birmingham, for *Tricolor Pelargonium* Miss Rylands, the foliage being similar to that of *Sophia Dumaresque*, but the flowers being quite double and pinkish white. Mr. Chater, Saffron Walden, exhibited *Hollyhocks*, to one of which, *Virgin Queen*, white, a first-class certificate was awarded. Mr. Tong, gardener to J. S. Maw, Esq., Enfield, exhibited well-grown tuberous *Begonias*.

A first-class certificate was awarded for double white *Pelargonium* *Amelio* Baltet (Lemoine). The white petals of this were extremely pure, the pips being thoroughly double and the trusses fine. The plant possesses a good habit, but it would be improved if the foliage was of a darker green. It is an excellent variety. It was exhibited from Chiswick, and had been sent to the *Pelargonium* Society by M. Lemoine of Nancy. From the Society's gardens came plants of *Hydrangea japonica* variegata, some having been grown under glass, and one in the open air, the former showing to great advantage; also an old plant, seldom seen, of *Dolichodeira tubiflora*, a *Tydea*-like plant, with tall spikes and pure white flowers, and but for being old would have been honoured; also small healthy plants of *Cissus discolor*.

#### NOTES AND GLEANINGS.

THE CARPET BEDDING in the gardens at Cleveland House, Clapham Park, will shortly be in perfection, and we recommend all who are interested in this mode of flower-garden decoration to inspect these superlative beds. By the kindness of the owner, Mr. S. Ralli, the gardens will be open to visitors after two o'clock on the afternoons of Tuesdays and Fridays throughout August and September. Last year these gardens were fully described on page 206, vol. xxix., and the beds were there referred to as the best of their kind in the vicinity of London. This year they are totally distinct in design, yet equally effective—indeed the centre bed surpasses the best beds of last year, and is a masterpiece of the art (for art it is as here carried out) of carpet bedding. It were futile attempting a description of this bed, and a diagram of its mode of planting would be little short of a mockery; to be understood the bed must be seen. *Nertera depressa* is extensively planted, and associated with *Sedum glaucum* the effect is charming. *Sedum acre* elegans is also extremely chaste, and the rich green *Sedum Lydium* is this year doing admirable service. But Mr. Legg's greatest "hit" is the introduction, as a green carpet plant, of *Mentha Pulegium gibraltarica* variety of the com-

mon Pennyroyal), it is close, dense, and of the brightest green, quite superseding *Tagetes*, *Cerastium arvense*, and all other dwarf green carpet plants. It grows freely, is perfectly hardy, and requires no pinching. In these beds not a flower is to be seen, and two of them are noticeable as containing no yellow, the colours being all soft neutral tints. Conspicuous in this pair of beds are a series of eardrops formed with succulents and "gems" of *Nertera*. This small garden is highly worthy a visit as containing the most perfect type of carpet bedding near the metropolis, and Mr. Legg is to be congratulated on his success.

— We have received from Messrs. Rivers & Son of Sawbridgeworth fruit of the PINE-APPLE NECTARINE, the largest we have ever seen. Indeed it is the largest Nectarine of any kind we have ever seen. The longitudinal circumference was exactly 9 inches, and the latitudinal  $8\frac{1}{2}$  inches; the weight being 6 ozs. and 3 drachms. The fruit was grown on a standard cordon.

— We very much regret to hear that the numerous small nurserymen and florists in the vicinity of Tottenham, Hornsey, and Leyton have had their crops much injured by the recent severe hailstorm, which was noticed in our columns last week. For this we think a subscription justified, and we are glad that a Committee, consisting of Mr. Fraser, Mr. Ware, Mr. Sweet, and Mr. Maller, is formed for raising it. These nurserymen have suffered extensively, and the assistance and support which they are enlisting on behalf of those who are less able to bear the losses to which they have been subjected is urgently needed. A meeting was announced to be held yesterday evening at the Green Dragon, Bishopsgate Street, London, to take into consideration the best means of raising a fund to relieve the pressing necessities of the sufferers, the circular convening the meeting stating, after a visit to the places named, that "the injury done to the glass and plants is of such a deplorable nature that it is almost or quite sufficient to ruin" many who were overtaken with the violent storm. Calamities such as these show the importance of insuring in the Hailstorm Insurance Company, and similar losses will doubtless be provided against in the future; but in the meantime assistance is greatly required and will be appreciated. Mr. Fraser, The Nurseries, Lea Bridge Road, London, will receive subscriptions and communications.

— THE programme of the INTERNATIONAL HORTICULTURAL EXHIBITION to be held at Amsterdam in the April of next year has been issued, and may be had from Mr. H. Grönwegen, General Secretary, 5, Oetewalerweg, Amsterdam. The value of the prizes to be awarded should be announced.

— BEFORE concluding (see p. 82) that nothing will destroy the ONION MAGGOT, let your readers pour over the bed attacked water just off the boil, and perhaps they will be surprised to find how much more heat the vegetable can stand than maggot life.—JOSEPH WITHERSPOON.

— A CORRESPONDENT, "A. Y.," writes as follows:—"J. Muir, in his able article on protecting fruit, recommends sour beer in bottles to be hung up in the house for the DESTRUCTION OF WASPS. If any of your readers were to place in the house two or three Tomato plants or more, according to the size of the structure, they would be proof against wasps without going to the expense or trouble of netting, tiffany, or paper bags."

— It is the beautiful and unrivalled forms of FERN-LIFE which fling over Devonshire scenery its almost indescribable charm. Peer at low tide into yon dark and dripping cavern which yawns upon the sea! The bright sunshine that dances upon the rippling waves pauses at the cavern's mouth, as if not daring to penetrate its gloomy depths. But one tiny gleam of light has ventured to cross the threshold; and sparkling on the dripping water, it flashes through the opaque blackness a kind of electric light. As the water falls, drip, drip, into the pool below, the light increases, and then—oh, glorious sight!—you see at the side and on the roof of this lonesome sea-cave the beautiful Sea Spleenwort (*Asplenium marinum*), hiding its roots in the cavern walls, and spreading out its bright-green and shining fronds that they may luxuriate in the dark humidity of its chosen retreat. Or peer over yonder cliff, whose inaccessible sides overhang the seething waves! Look closely into the shady cleft which nestles under yon projecting spur! There you may see, far out of your reach, one of the most rare and exquisite of the British Ferns—the Maidenhair (*Adiantum Capillus-Veneris*). Could you venture near enough to grasp it in your hand you would indeed recognise that it is one of the most exquisite of plants. Its fine, black, wiry frond-stems, like a dark maiden's hair—it is most appropriately named—

rise in clusters from its crown; the main frond-stems being branched with smaller and more beautiful hair-like stems, which bear upon their tender points the delicate light-green fan-shaped leaflets. Wandering through the cool lanes of Devonshire you may, too, meet with the fragrant hay-scented Buckler Fern (*Lastrea æmula*) which emits so beautiful an odour when pressed in the hand; with the delicately and transparently leaved Marsh Buckler Fern (*Lastrea Thelypteris*); with the Mountain Buckler Fern (*Lastrea montana*), whose silvery fronds make the air fragrant when you tread upon them in their insipient unrolled state. But these varieties are not to be commonly encountered in every Devonshire lane. And still rarer—though found in Devonshire—are the Lanceolate Spleenwort (*Asplenium lanceolatum*), the tiny Forked Spleenwort (*A. septentrionale*), the Tunbridge Filmy Fern (*Hymenophyllum tunbridgense*), and Wilson's Filmy Fern (*H. Wilsoni*) The Moonwort (*Botrychium Lunaria*), and the common Adders-tongue (*Ophioglossum vulgatum*), are also Ferns of Devonshire growth.—(HEATH'S "The Fern Paradise.")

— A WRITER in "Nature" states that "one of the most valuable products both of Bosnia and Servia, as at present developed, lies in their PLUM CROPS, many of the peasantry depending entirely on these fruits as the means of subsistence through a great part of the year. The Plums, after being gathered, are mostly dried in the form of prunes, the secret or art of drying being known only to themselves. The Bosnian Plums are considered of a better quality than those either from Servia, Croatia, or Austria. A quantity of spirit is likewise prepared from these fruits. Amongst other vegetable products of the country may be included Tobacco, Potatoes, Flax, Hemp, Walnuts; and amongst cereals, Wheat, Maize, Barley, Oats, Rye, Millet, &c. Wheat and Maize are the principal food plants consumed in the country, some of the other products being exported in comparatively large quantities."

— As proof of the hardiness of the newer kinds of the TUBEROUS-ROOTED BEGONIAS raised by Messrs. James Veitch and Sons, there are now to be seen flowering in the Chelsea Nursery rows of plants in the open ground, and where the tubers have remained throughout the winter without any protection having been given them further than that afforded by the walls of the houses near which the plants are growing. Other and choicer varieties, which are extremely beautiful, which are being grown in pots, have the lights removed from them whenever the weather is favourable, and under this cool treatment the plants flourish admirably. That the plants require no other accommodation than that afforded by cold frames, renders them additionally valuable. Many errors are made in keeping these elegant and brilliant summer-flowering plants too warm and close. They do not require more heat than Fuchsias and Geraniums. In the Orchid house is now flowering the new *Zygopetalum Sedeni*, the result of a cross between *Z. maxillare* and *Z. Mackayi*, and partaking of the qualities of both parents. The lip is purple mottled with white, the sepals and petals being very dark. This is a distinct and beautiful Orchid, and is as sweet as a Lily. *Lælia elegans alba* is also flowering, and is as beautiful as it is rare, the petals and sepals being exceedingly pure, and the lip of the richest violet-purple imaginable. A most valuable plant.

## CHAPTERS ON INSECTS FOR GARDENERS.

No. 10.

I THINK if there is one insect above others which the majority of gardeners regard with an especial hatred it is the aphid in its multitudinous varieties. Many are the names expressive of dislike which I have heard hurled at these "vile vermin," but I do not remember that I ever heard anyone insult them by calling them "bugs," though bugs they are properly according to our entomological classification. "I am afraid," said I in sympathising tones to a friend the other day, "that this will prove a great aphid year." With a deep sigh he reflectively answered, "When is there a year that isn't a great aphid year?" True enough, not a season is free from visitations of these prolific and persevering parasites; still there are differences, and in certain years some of our garden plants enjoy a comparative repose from aphid attacks, while in other years the cry is, "Aphis, aphis everywhere;" and gardeners are tired of smoking, washing, and syringing. My usual prognostic is a cold May with not much rain and plenty of wind. When that occurs I expect to find aphides abundant; heavy rainfall is objectionable to these insects, and I do not think they like very hot weather.

Proceeding with the second division of the Hemipterous order, to which, when we speak familiarly, we apply the English name "bugs," inelegant though it be, just as we call the Coleoptera "beetles," its importance will be seen from the mention of the aphids and its allies, which, as I have stated, occupy an unpleasantly prominent place in the order, being ranked in the second great division, that of the Homoptera. This word, of Greek derivation, indicates a marked peculiarity in the wings. Whatever the forewings may be composed of, they are uniform throughout, while in the Heteroptera we have two different textures combined in the same pair of wings. Another notable difference between the divisions lies in the mouth, the Homopterous species having it set very deeply in the head, so that, as Mr. Staveley expresses it by comparison, the organs of the mouth seem to spring from a part which in a man would be represented by the under side of the chin near the breast. There is, of course, the usual proboscis with bristle-like mandibles. Many of the females have ovipositors; and the female aphides in their power of producing fertile insects like themselves without intervening stages present us, as we shall see hereafter, with a curious and long unsuspected anomaly in insect history. Almost all these species are stout-bodied, mostly with short antennæ (but a few species have them very long), and the power of leaping is possessed by a good proportion of the species, though they do not invariably use it. Only a small section of the Homoptera is vocal, the rest of the species pursuing their work in silence. Also there are some luminous species, the Lantern Flies of warmer climes having their place here; of that group of the order we have English representatives, but not light-givers. All the species are terrestrial and pacific—I am not aware of one that preys upon its fellows; and as to the transformations, it is sufficient to state that the larva and pupa are not unlike the imago except in size, the pupa being active, exhibiting generally the wings partially developed. Some conceal themselves with substances exuded from their bodies.

The Homoptera break very easily into three natural groups, concerning the first of which I need not say much. In the Trimera the antennæ are very small, with either three or six joints, and the tarsi or feet also possess three joints. The family Cicadidæ only contains a solitary and rare British species, *Cicada anglica*, furnished with those vocal powers which have made these insects famous for ages. So deafening is the sound produced by troops of the Cicadas in tropical countries that they have been heard miles off, the male insects alone, however, thus making themselves notorious. In some districts these are called "grasshoppers," in others "locusts," from a notion of their destructiveness; but we have in England no representatives of the family that are injurious, though there are several species with beautifully veined wings which occur sometimes about meadows and woods. To the next family, the Fulgoridæ, I need devote little space; it is distinguished from the Cicadidæ by the position of the antennæ, which are inserted below the eyes. Though we have forty species or more in these islands, they rarely visit gardens or make themselves obnoxious by their habits, leading a retired life, and needing to be hunted up by the microscopist, who occasionally seeks them to make an object of the beaded and delicate forewings. Abroad, chiefly in South America, the Lantern Flies belonging to this family add brilliancy to the evening landscape by a light beside which our glow-worm sparkle would be but feeble. In the Cercopidæ, the third family of the Trimera, the insects are leapers, as are those in the last family, but the antennæ are situate between the eyes, not beneath them. The very abundant species called the Frog hopper, or Cuckoo-spit, is a good example of the family, though it is certainly devoid of any connection with the frog or the cuckoo. It may be noted, however, that the appellation "Frog hopper" is not incorrect, if we understand it as applying to the leaping habits of the perfect insect, though it is probable the origin was in a belief that the frog produced the spume or froth in which this larva is concealed. *Aphrophora spumaria*, the Latin name, is applicable enough to this particular species; and the generic name indicates the habit prevalent amongst its brethren, for in truth we have many of these Frog hoppers, though *A. spumaria* is the commonest. The frothy substance surrounding these larvæ is of course sap derived from the plant on which they are feeding, yet I think it is sap which has passed through the process of secretion, and not just as it leaves the plant. Oftentimes after rain the larvæ may be seen exposed, but they make all haste to involve themselves again in a liquid which protects them from the sun

and also from the attacks of enemies. As these Frog hoppers waste thus more than they need as nutriment (for at times the froth flows down in good-sized clear drops), plants infested by them must suffer a loss of vitality; I must admit, however, that naturalists have argued otherwise, believing, perhaps, that bleeding may be as good for plants as our ancestors thought it was for the human body. Necessarily many gardeners do not connect the mature Frog hopper—leaping from leaf to leaf with a jump said to represent a spring of 400 yards, supposing a man could leap so far in proportion to his size—and the frothy deposit on the bushes in early summer. All the Frog hoppers have roof-like wings, also a curious enlargement of the front joint of the thorax, which in two or three species sticks out like a kind of keel, covering the wings. *Ptyelus bifasciatus* is a singular individual in this family, having the wings crossed by two bands, while the ground colour in different specimens is of various shades between grey and black. *Cercopsis sanguinolenta* is a species with vivid tints of scarlet, and a velvety appearance in the wings caused by a crowd of minute rounded spots of black. It haunts Ferns, though fortunately it is an uncommon insect.

The second section in this subdivision of the Hemiptera is called Dimera from the feet having only two joints; the antennæ are also longer than in the Trimera, the wings being usually carried by those imagos that possess them in a roof-like position. If I name the family of the Psyllidæ first it is not out of compliment because these insects are of any service to the garden, for the case is just the reverse, but their being endowed with the power of leaping; the ten-jointed antennæ and the large thorax seem to place them in advance of their brethren the aphides. The two families are often confounded by the ordinary observer, since the Psyllidæ, though able to jump, do not always exert this faculty, and in size and habit the families are nearly alike, even to the possession of certain species which can waft themselves along by small tufts of a cottony exudation, in which at other times they find concealment. One or two species of the genus *Psylla* have been called "Hoppers," and others have received the name of "Chermes," quite as un-English as the appellation "Psylla," though some writers think it preferable. *Psylla Mali* has, doubtless, been frequently supposed to be the hated "American blight," for it is surrounded during its larval condition by a mass of whitish threads, which may be deemed to represent in a different form the saliva of the Cuckoo-spit or Frog hopper, and like that the cottony substance is secreted, not manufactured, by the insect. The specialty of these larvæ is the bud of the Apple; at times the imagos may be seen on the trunks of the trees in little parties, conspicuous, though so small, from their brilliantly white wings and yellow-ringed bodies. The Pear also has its kindred pest in *Psylla Pyri* similar to the Apple-haunting species, save that the body is greenish. This species is discovered to make at one period the young shoots the object of its attack, at another the blossoms, and it has even been discovered upon the fruit. These larvæ do not exude a cottony covering, apparently as a rule finding protection in their numbers, nor has it been ascertained that this and others of the Psyllæ have so many parasitic foes as have the aphides. The gardener's most effectual modes of "settling" them are, I suppose, fumigation with tobacco or similar narcotics where that can be done, and washing the trees infected. That beautiful plant the Camellia, source of much care and trouble as well as enjoyment, has its Chermes as well as its aphids and its coccous; and *Psylla Cratægi*, though thus named, is a visitant to the houses where Camellias are congregated together, disfiguring the plants or checking their growth. Hardly a Box tree grows anywhere which has not had the mark of *Psylla Buxi* set upon it; in this case the insect does not appear to exhaust the strength of the shrub, but it gives an ungraceful look to the ends of the twigs and branches. The Rose, too, has its parasite of this family in the form of an insect known as *Typhlocyba Rosæ*, which often escapes particular notice amongst the multitude of enemies attacking the queen of garden flowers.

The Psyllidæ do not, I believe, produce honeydew in any instance, this peculiar substance being attributable to aphides only. These important insects I must defer my notice of until the succeeding paper; but as the season when honeydew is principally conspicuous has recently passed over, I will here make a few statements with regard to it which may serve to set some gardeners thinking on the subject. Of course I do not submit them as certainties, like geometrical axioms, and I shall be glad to be corrected by those whose opportunities of

observation have been more extensive than mine. Honeydew, then, as I take it, is not exuded from plants under any circumstances, but it closely resembles vegetable juices, because, though deposited by aphides, it undergoes little change in the process of secretion. Secondly, it is usually, but not invariably, connected with migrations of aphides, the insects on arriving at a new locality depositing honeydew on the upper surfaces of the leaves; they may possibly leave honeydew behind them on departure, but this is doubtful. Thirdly, honeydew does no injury to the plants on which it is found, though it is important as a sign of aphid presence. Fourthly, although it has been thought that honeydew is connected with certain states of the weather, it is only in a secondary sense, because those states of weather have to do with aphid migrations. Fifthly, these migrations very frequently occur on dull days in spring or early summer when there is but little wind stirring and the air is dry owing to the wind being easterly. If aphides generally travel with an east wind, there would be additional reason for regarding breezes from that quarter as blighting and inauspicious in their effects.—J. R. S. C.

### WHITE TRUFFLE AND OTHER RARE FUNGI.

It has frequently been remarked that while certain kinds of fungi appear every year in the same locality, others are extremely capricious as to the time of their occurrence and the number of specimens produced. A single specimen, for instance

Fig. 9.—White Truffle.

of *Paxillus paradoxus*, an Hungarian species, occurred last year, one in the west of England and the other in Kent, and in both instances was perfectly new to the British mycologist. The genus *Sprassis* was utterly unknown in this country till lately, but has now turned up in more than one locality. The White Truffle of Sowerby is a remarkable instance of the excessive scarcity of a particular species. From the time when it was figured by Sowerby a single specimen only occurred to Mr. Currey at Blackheath; Cooke found one also, and it has occurred in Herefordshire, and we have heard that it has lately been found under Oaks at Windsor—a species, it may be remarked, which has never been found by Messrs. Tulane in their numerous researches, though it was not unknown to Vittadini. Corda appears to be the only one who has hitherto met with it in abundance, and excellent figures are given from his pencil in Krombholz grand volume. It was therefore with peculiar

pleasure, during an excursion to the very interesting grounds of Rockingham Castle in Northamptonshire, that fine specimens of this rare plant were given to us by the excellent gardener Mr. Brown, who has found it more than once under Oak trees, not truly subterranean, but just peeping out of the ground, as is sometimes the case with the common Truffle, as in Somersetshire, where we have seen it cut in half in mowing the lawns.

The White Truffle appears to be very common in Bohemia, where it occurs in shady woods, and is much valued on account of its delicate flavour. It is too rare in this country to make it of much importance.—M. J. B.

### FEATHERED HELPS IN GARDENS.

Of the value of peewits in gardens my experience enables me to speak in the highest possible terms of approval. For some years I was in a garden in which seagulls were kept as grub-scarvers; also hawks as bird-scarers, and both kinds of birds were extremely useful. I was in another walled garden in which was enclosed from two to half a dozen peewits—plovers—as the birds could be obtained, and I found these birds decidedly preferable to the gulls.

Than peewits no birds can possibly be more diligent in hunting-out and devouring slugs, snails, and grubs of all kinds which infest the garden. I have seen them run their long bills round the crowns of Strawberry plants, passing from plant to plant for an hour together, and many times I have watched them insert their bills as deeply as possible into the surface of bare ground and “fish-out” worms and grubs. I have seen them try the ground for a hundred times in succession in searching for hidden food, and seldom searching in vain, finding by a wonderful instinct what human eyes could not see or man's reason fathom.

These birds were treated as advised by “WILTSHIRE RECTOR” on page 72, being cared for and prized as valuable assistants, also ornamental. Yet as stated, kindly as they may be treated, they will escape if an opportunity is afforded them, but after a time they become in a measure tame, especially when three or four of them have been preserved together for a few years. On one occasion by a neglect of the timely clipping of one wing of each bird, one of birds became able to fly perfectly, and did fly over the tree tops but not far, and “returned to its mates” in the garden, but at length, after perhaps having returned a hundred times, it flew away altogether.

During a severe winter, although the birds were fed, they died, and for three seasons we were without peewits, and year by year the injury from slugs and snails became greater, rendering liming and hand-picking necessary to preserve the crops of vegetables and Strawberries. More birds were eventually obtained, and slugs and such-like vermin gave us no more trouble. Where these birds can be preserved between walls they may be safely left to look after the slugs. The birds are ever foraging and ever devouring, and of the greatest value in a garden, and not, on the other hand, doing the slightest harm in any way.

But, as has been well said, they must have water at all times, and food also in frosty and very dry weather. They must also be placed under shelter during a long period of very severe weather, or be they ever so well fed they will succumb to the cold. We used to place them in cold pits or frames when the frost was protracted and unusually severe. In districts where the birds inhabit, young birds may be purchased for 6d. each from boys working on farms.

It is remarkable that old egg-hunters know immediately on entering a field not only whether there are any nests in it, but whether the nests contain eggs or whether they contain young birds. This information is given by the peculiar flights and noise of the old birds: if these are not understood the discovery of the nests is most difficult, but if the habits of the birds are known their nests are found with certainty and ease.

These birds are as useful in gardens as cats are in barns, and I cheerfully corroborate all that has been written of their value.—A LINCOLNSHIRE GARDENER.

### BISHOPSTOWE.

WALKING from Torquay, and turning from the cliffs of Anstis Cove to reach some one of the neighbourhood's special lanes, I came in sight of Bishopstowe. This is a modern residence, built and named by Dr. Philpots, formerly Bishop of Exeter. He purchased the ground, made it his favourite

residence, and died here. His executors sold it to its present occupier, Sampson Hanbury, Esq. The house is descended from by two terraces ornamented by flower beds, and overlooks the gardens. The dressed grounds are four and a half acres, and the kitchen garden one and a half acre in extent. The soil is not good for gardening, clay predominating; but this suits the Roses, which are superior, and, which I did not expect, a selection of Conifers. There are only two specimens which are not thriving. Along each side of the main walk is a row of Columbines, the most varied in form and colour that I have yet seen. Geraniums are outdoors throughout the year, but they were killed by the frosts of last winter. The crop of Grapes is very good and regular, but early forcing is not desired, and the Black Hamburgs and Muscats are grown in the same house. Every department is well cultivated, and

to know whether the plant is naturally and healthily casting its leaves or no. If a fine glossy green or well-mealed white growth is being developed as the large outer leaves decay the plant is all right. I do not like to see an Auricula lose its foliage almost as fast as it gets it, nor a leaf decay out of its turn—that is, before the older foliage outside it dies; nor again to see leaves curled with yellow streaks that seem to cripple them. I should not wish to pronounce hastily upon your correspondent's plants, still less to mislead him. Perhaps I may hear again if nothing I have said agrees with his case. But certainly at this time the Auricula is parting with its large outer foliage, and the plants are starting into active growth at the heart.

Should your correspondent ever, in his young days with the Auricula, be suddenly made anxious to know whether they are

Fig 10.—BISHOPSTOWE.

bears witness to the care and skill of Mr. William Wood, the head gardener.

The broad border of the central terrace walk is planted with mixed Gladioluses next the wall, then a row of *Tagetes signata pumila*, then a row of *Geranium Vesuvius* and a row of Mrs. Pollock *Geranium*, edged with *Lobelia Blue King*. The narrow border next the high wall is planted with *Zinnias*, *Asters*, *Stocks*, *Helichrysums*, and mixed *Geraniums*. The vases, about eighty in number, are filled with various *Geraniums*, edged with *Sedums*, *Lobelias*, &c.

There are many plants that grow and thrive here that require a greenhouse in the eastern counties. *Myrtles*, *Veronicas*, &c., are quite hardy and flower out of doors. Fine plants of *Veronica* are here 8 feet high and in fine bloom, and usually continue in flower up to Christmas. The *Roses* were spoiled by the hot weather, and the kitchen-garden crops suffered from the same cause, the soil being shallow, resting on the limestone.

#### AURICULA LEAVES DECAYING.

FROM YOUR correspondent "ALFRED" come two large yellow leaves with the complaint that many are turning so. There is nothing about the specimens sent to indicate any other process than that of natural decay. They seem to have belonged to the blooming foliage, which at this season is ready to pass away in proportion as the autumn growth sets in. It is easy

right or not, and have no florist friend at hand to consult with, I can refer him to a very trusty informant, probably close by, who will tell him at a glance. Let him seek out a bunch of any common border Auricula in his own or some old-fashioned cottage garden, and the phase of rude health which these untutored savages will exhibit is just the condition that his cultured plants should show. He will only feel sorry that there are no such clumps of Page's Champion in existence.—F. D. HORNER, *Kirkby Malzeard, Ripon*.

#### OUR BORDER FLOWERS—MONARDAS.

WE need not for one moment hesitate to say that *Monardas* though a small family are among the neglected plants; seldom seen and less cared for; mistaken by many for *Salvias*, from which they are quite distinct; said to be from North America; introduced to us so long ago as 1656. We sometimes come across one of these fine old border flowers, and when met with we often find an unsightly object. Left to themselves they soon get into a semi-wild state, as though they wanted to hide from our view. When well in hand they are of robust habit, and have a graceful appearance in open spaces in shrubbery borders. In moderately good soil they will do well and in a great measure look after themselves, bearing a good deal of rough usage, and living often a long time.

We seldom see more than one or two of this family in cultivation. *Monarda purpurea* and *M. didyma* are sometimes

met with. There is a white kind called *Monarda Russeliana*, a very desirable plant of much less habit than the foregoing, but when cared for and well established is a very attractive plant, continuing in bloom for a long time. *Monarda gracilis* is the least of the race; its purple flowers prove attractive in our borders.

There are other kinds equally ornamental, but I fear that some of them only exist on paper. They do not require the attention that some of our border flowers do. They thrive in ordinary garden soil, but they are the better for a little liberal treatment in the way of fresh loam and well-decomposed manure when replanted, which is best done in spring when growth has commenced. When the flower stems rise they are the better for being thinned; they show themselves to greater advantage. They are the better for being neatly staked to prevent them being broken by the wind. Increased by division in the spring. When in good condition they are useful for exhibition, and will repay any extra labour they may entail on the cultivator.—VERITAS.

### TODEA SUPERBA AS A ROOM FERN.

THERE is a pretty general impression that it is difficult if not impossible to grow this exquisitely lovely Fern in the sitting-room. It may interest some of your readers to know how it may, by very simple means, be reared to the greatest beauty—and, I am satisfied, if this were necessary or desirable, to exhibition size—with much less trouble or difficulty than any one of the *Adiantum* type.

Four years ago our plant was a tiny seedling with a couple of fronds barely an inch long, and we were warned by everyone that it would be dead in a month. The first object was to secure it so far as could be done in a sitting-room constantly occupied, and the greater part of the year with both gaslight and fire heat—its natural conditions—a damp atmosphere, very moderate light, and complete exclusion from direct sunrays. With this view the thumb-pot containing it was sunk to rather over its brim in a shallow seed-pan filled with live *Hypnum* moss, and a bell-glass placed over the whole. A 3-inch one was at first sufficient. We chose *Hypnum* in preference to either sphagnum or any of the dwarf *Selaginellas*, in the hope that it would keep always fresh and green under these conditions—a hope which has been amply fulfilled. At varying times—from once in ten days to once a month according to the weather—*Todea* and moss alike were dewed well over with tepid water through a fine rose, the glass being at once replaced.

This treatment has been ever since continued, the containing vessel and the bell-glasses being enlarged as required. It now more than fills a 24-inch glass, the largest I have been able to procure. There are upwards of fifty fronds, from 8 to 15 inches long, and 6 to 9 broad; and were a larger glass procurable, or greater size manageable, it could be easily grown to rival the largest exhibition specimen. The persistence of the fronds is extraordinary. Only three have ever been cut away, and these were so because they had been partially scorched by the sun having accidentally struck on them where they touched the glass.

Its position has always been on the floor, at a north bow-window, under a large Wardian case, which to a great extent shades it. In these circumstances a certain degree of blanching might have been expected. On the contrary, the depth of the green far surpasses all I have seen in any specimen grown in the ordinary way; the fronds are always gemmed over with myriads of tiny diamonds, and their delicate transparency is such that on holding a sheet of white paper behind one of them its whole interior structure comes into view. Direct sunlight is never allowed to strike on it. It has only once been repotted, a few months after we got it, and then only into a 3-inch pot, in which it still remains. On that occasion we found that nearly all the curious filmy roots had left the pot, striking over its surface and rambling all through the *Hypnum*. It has never since shown the least sign of being straitened for pot room, or failing to find in the moss all the sustenance it needs. The moss, again, was supplied with no soil whatever, and has all along maintained the most vigorous health, and a delicacy of colour almost rivalling that of the *Todea*, apparently from the slow decay of the lower portions of it.

For two or three years it has been seeding freely; and it is not easy to give an idea, to those who have not seen it in this state, how the tiny, jet-black gleaming sporangia add to the beauty of the fronds. Unlike any genera I can at present

recall, these fertile fronds remain persistent and do not decay. Last year one or two seedlings were discovered struggling up through the moss, one of which was safely potted-off, and is now being brought up, with every prospect of success, exactly like its parent. This year there is the appearance of a large crop of this, though of course it is doubtful whether they will not be overpowered in their first conefrond-looking stage by the *Hypnum*.

The plant was one of a large batch of seedlings raised by Mr. Patterson, Millbank, near Edinburgh. Whether it has to some extent “sported,” or whether one or two peculiarities are due to the way in which it has been grown, I cannot say. These peculiarities are, that the stipe is longer than in the normal form; the fronds are more triangular in form; and they are also more “fuzzy,” as my daughter, whose pet it is, calls it. I incline, however, to think there has been a slight degree of sporting, as our seedling, so far as we can yet judge, though under the very same treatment, approaches much more closely the normal type.

Any of your Fern-loving readers who may be induced to try the experiment will, I am satisfied, find this exquisite species, once started, give less trouble to grow to full beauty in fire-heated, gas-lighted rooms than attends our own Lady Fern, by following out this mode of culture, or such modification of it as may occur to them. The essential points are—a constantly damp atmosphere around the plant; a considerable degree of shade and careful exclusion of direct sunrays from it; and any free loose medium, such as *Hypnum* or other dwarf moss, through which the roots may ramble.—M. (in *The Gardener*).

### NEW EDITION.

*The Tree-Lifter, or a New Method of Transplanting Forest Trees* By Col. GEORGE GREENWOOD. Third Edition. London: Longmans & Co.

We have mentioned favourably the previous editions, and it is for the information of new readers that we quote the following passage from the volume:—

“Among the advantages of transplanting with ‘the tree-lifter’ may be reckoned its cheapness. Its simplicity is such that the whole may be performed, and even single-handed, by a common day labourer. One man may plant one tree per day of from 25 to 30 feet in height. To transplant trees without the ball of earth requires great skill, care, labour, and expense in tracing out the small fibres of the roots, whose extreme points, with their supposed spongioles, could by no delicacy of operation be retained, and which after all are nearly valueless. All transplanted trees are the better for being watered, but with the ball of earth this is by no means necessary. To transplant without the ball of earth, and not to water for at least two summers, is hopeless.”

### WARDIAN CASES AND FERNERIES.

[From the Transactions of the Massachusetts Horticultural Society.]

PLANT CASES as we know them are classed under two heads—first the Wardian case, in which are grown foliage plants, Ferns, &c.; plants too large or too coarse to look well in a small case. Although the first Ward’s case was only a bottle, in which by accident Mr. Ward discovered that plant life could be sustained, from some cause or other we seem to have adopted the name Fernery for cases that are covered with a glass shade, in which only the more delicate or smaller varieties of Ferns are cultivated. The schedule of this Society limits the size of the Fern case to 15 inches in diameter.

In drawing a line between the Wardian case and fernery, the Flower Committee ruled out a case put up for competition that was filled mostly with foliage plants, deciding that such plants were not admissible to a fernery except when they were of such size and character as would not interfere with the general beauty and harmony of the whole, and then only in a small proportion to the number of plants used.

In this article I will endeavour to give some experience I have had with cases varying in size from 4 to 15 inches in diameter.

The case may be made of tin, earthenware, or wood; it matters not which, so long as proper regard is had to drainage. This, as in Wardian cases, is of vital importance to the healthy growth of plants under the Fern shade. I say this is of the first importance, as many persons who have the management of ferneries use so little judgment in their care, that

without a proper outlet for water the cases soon become perfectly sodden. I have seen more plants destroyed in cases from the want of drainage and from overwatering than from any other cause. Most of the failures I have met with have arisen from either too much water or too little light, and frequently both combined, although the persons having them in charge have strenuously denied that any more water had been used than the plants required, and have insisted that they were placed in a very light situation. The light situation is usually quite a dark one—generally a space between two windows, with a dead wall behind it, or in a corner receiving a little light obliquely from a window 2 or 3 feet distant. When the plants are turned out it is found that they have been treated as aquatics, and kept fairly up to their knees in mud and water. Then people wonder at their want of success.

The HANGING FERNERY was my first attempt in this direction. I designed it to take the place of the hanging basket, which so seldom appears in good condition in the home. The case was turned from walnut, several pieces being glued and nailed together to get the proper depth, and also to keep the wood from warping. It tapered to a point at the bottom, to give lightness to its appearance. A zinc pan with a rim to receive the shade fitted the case loosely enough to be readily removed when watering was necessary. This case as first constructed was covered with a shade 8 inches in diameter and 10 inches high, and was suspended by silvered copper wire. The case first exhibited in this hall in June, 1871, had a shade 12 inches in diameter and 14 inches high; was elaborately trimmed from maple and walnut, ornamented with ebony trimmings, and filled with the following named plants:—*Onychium japonicum*, *Adiantum assimile*, *A. cuneatum*, *Selaginella Wildenowii*, *Panicum variegatum*, *Fittonia Pearcei*, *F. argyoneura*, *Lycopodium denticulatum* var., and *Mitchella repens*, some Lichens and Wood Mosses. It was awarded the Society's silver medal.

This case when taken from the hall was suspended in my window, where it received the morning sun for about an hour each day, and was not disturbed again till January, excepting when it was occasionally turned to the light. It was then a mass of green. I noticed considerable soil on the glass, carried up by slugs in their nocturnal rambles; also some decayed fronds of the *Adiantum*. Altogether it was as much of a success as a close case could be, and would probably satisfy most people who grow plants for home decoration.

There are some plants that seem better suited to a close case than to any other situation. They are confined chiefly to the Lycopods and Selaginellas. Many of them are very beautiful, rivalling, and in some cases closely resembling, their allies the Ferns in beauty of form and delicate feathery appearance. They make superb specimens grown singly under a shade; and I consider this the most satisfactory way to grow them, having the case large enough to fully develop their beauty of form and habit. Their growth is generally quite rapid, and to anyone who delights in a well-grown plant the culture is worth trial. *Selaginella Lyallii*, *S. africana*, *S. plumosa*, *S. umbrosa*, and *S. triangularis* make quite large plants and are erect in habit. There are many others usually found in plant catalogues, and as far as I have tested them all are eminently fitted for close cases, and their growth is much more rapid than when grown outside. I usually combine them with Ferns in the arrangement of a case, and think the effect is much better for the combination.

The *Fittonias* are another class of plants which are favourites with me. Their bright crimson and silver veinings are a great acquisition to the fernery, lighting it up wonderfully, and seemingly never out of place, no matter what the size of the case may be. They also make superb plants by themselves. I once had a plant of *F. gigantea* which filled a shade 12 inches in diameter and 14 inches high. It was the finest plant of the kind I ever met with. Its habit became erect, and the colour of the foliage seemed very much more brilliant than we ordinarily find it. But the variety is too coarse to be grown satisfactorily with small Ferns. The Wardian case is the more suitable place for it. *F. Pearcei* is the best for all purposes; being a vigorous grower a mere scrap soon produces a good plant, and it will live under almost any treatment in a close case. Its habit is not so recumbent as when grown without. *F. argyoneura* is very beautiful, but it has one fault—that of damping-off when it is chilled, thus spoiling it for winter use, unless in a very warm situation: but it is just the plant for summer use. There are so few plants of a white or silvery appearance suitable for this purpose, that I use the

*Fittonia argyoneura* as long as the foliage will hang together, and then replace it with something else.

A few weeks since I had the good fortune to be shown a plant of *Todea superba* growing in a Wardian case. The case was about 2 feet square, and as many feet high, with a flat top. A pan about 8 inches in diameter, filled with this truly superb plant in vigorous growth, occupied the centre. Other Filmy Ferns were planted out in the case; but this, the grand object of the whole, was elevated several inches above the others, showing conspicuously its full beauty. An English author says of it, "Delicate and fragile, with its semi-transparent fronds, it looks like tufts of the most beautiful seaweed plucked from the decorations of a mermaid's ocean home." I have seen larger plants of this species, but none in such fine condition. It was grown in a cool room near a west window, the light partly obscured by a drawn shade. This plant is just the thing for a large Fern shade, as it needs as little air as the Selaginellas, very little light, and a cool situation, and when once established needs but little attention. The Filmy Ferns are eminently fitted for growing singly in cases by themselves. The only objection is the expense of many of them, but I would rather have one plant of *Todea superba* than dozens of ordinary Ferns.

The great difficulty I have always found in ferneries is to reach the plants after they have filled or partly filled the case. It is easy enough to remove the shade, but to replace it so that the plants may retain their former position is not so easy. This is so with regard to delicate Ferns; the fronds will tip about, look out of place, and otherwise mar the arrangement. If you could only reach them from the top all would be remedied very quickly. Frequently I have been forced to allow a large slug to have his own way rather than disturb the shade when the case was looking well, and in many instances have allowed decayed fronds to remain rather than run the risk of destroying the arrangement by removing the shade. It was almost as much on this account as for ventilation that I constructed the dome-top or ventilated Fern case, which is as easily managed as an ordinary Wardian case. Lifting the dome does not disarrange the plants, as they are all confined within the cylinder, which need never be disturbed for this purpose. This case is constructed as follows:—

The case or stand is of wood, 6 inches deep, and resting upon three small feet. There is a large opening underneath, covered with a moveable slide to admit or exclude the air. It has a zinc pan one-half an inch less all round than the wooden case. This half-inch space is covered all around at the top of the pan, which leaves a flat surface of zinc 1 inch wide, with an outside rim to receive the glass cylinder. This flat surface of zinc is pierced with half-inch holes in its entire circumference about 3 inches apart. When the glass cylinder is in place the half-inch holes are inside the case. The cylinder, of annealed glass, fits neatly into the zinc rim, and is 15 inches in diameter by 14 inches in height. Encircling the upper edge of the cylinder is a copper rim 1 inch wide, with edge turned downward on the outside a quarter of an inch wide to fit on to the cylinder. The flat surface of the rim is perforated with quarter-inch holes, and the inner edge turns up a quarter of an inch to receive the dome or cover, which is 8 inches high and 12½ inches in diameter. The holes in this copper rim are on the outside, so that when the valve in the bottom of the case is open the air passes up through the holes round the zinc pan and out at the copper rim. The whole case when complete stands 29 inches high from the table.

This case was first exhibited in 1873, and was filled at that time with *Onychium japonicum*, *Adiantum cuneatum*, *A. assimile*, *Panicum variegatum*, *Selaginella Wildenowii*, *S. stolonifera*, *S. Martensii*, *Fittonia Pearcei*, *F. argyoneura*, and *Lycopodium denticulatum* var. A perforated cocoanut shell filled with *Adiantum assimile* was suspended from the top, giving completeness to the whole. This case is quite an expensive one, and can never become popular on that account; but for convenience in the management and culture of plants it has no rival. It received the Society's silver medal at the time of the first exhibition.

Generally, too many and too large plants are crowded into the fernery, giving it a heavy and unsightly appearance, and filling the shade completely at the outset without room for further growth. *Dracenas* and other plants of this kind make a fine display in the Wardian case, but are certainly out of place under a glass shade. I know it is very difficult even for those too who are not wanting in taste in other matters to understand this.

There are very few foliage plants that can be introduced into the fernery. I would recommend only plants of dwarf habit, such as *Panicum variegatum*, a very pretty Grass, with pink, white, and green foliage; and a small variety of *Bambusa*. *Cyperus alternifolius* var. is quite pretty when a small plant, but the growth is almost too rapid for a Fern case of an ordinary size. The foliage is light and graceful, and contrasts prettily with Ferns. It is a charming plant for the Wardian case.

Rockwork in a case of the size just described has a very pretty effect when well arranged. This is a difficult matter to accomplish, and I generally prefer the case filled with plants rather than rocks, though for variety I occasionally introduce them. I use coke and pumice stone soaked in water, and sprinkled with cement to give colour. These substances are very light, and answer the purpose well. Quite small plants only are fit to be used with the rocks.

I have had this ventilated case filled with the following named plants, and the effect was highly satisfactory:—*Nephrolepis exaltata*, *Adiantum colpodese*, *Onychium japonicum*, *Selaginella umbrosa*, *S. Wildenovii*, *Panicum variegatum*, *Lycopodium denticulatum* var.; near the glass *Fittonia Pearcei*, *F. argyroneura* and *Peperomia maculosa*, and suspended in the shell a plant of *Selaginella coesium*. This last is the prettiest basket plant I have ever used for summer decoration.

Among our native plants are many charming Ferns that will soon accustom themselves to the confinement of the case. *Asplenium ebeneum* and *A. trichomanes* are very pretty Ferns for rockwork; *Adiantum pedatum* is a lovely Fern for a case, but requires rest in winter. *Polypodium vulgare* is pretty by contrast with those more delicate. There are several *Selaginellas* which will soon become quite at home in the Fern case, and will be valuable acquisitions. *Equisetums* are pretty, and so different in their character and foliage from other plants that one would hardly wish to be without them. Almost anywhere in the woods and swamps beautiful and delicate plants may be found that will grace any fernery. Many gems are often discovered in this way. A favourite of mine is the *Mitchella repens* or Partridge Berry Vine, which takes readily to the close case, its bright red berries remaining perfect in their beauty for a long time. This plant always produces a wonderful effect, and there is nothing prettier for any case, no matter with what else it may be filled.

**Management.**—In the selection of a Fern case I should choose one with an outlet for drainage. This I have already said is very essential, especially for a novice. If there is no drainage water must be used very sparingly. Crocks and small pieces of charcoal, covered lightly with old moss to keep the soil from sifting down through, are the best for drainage. I prefer a case constructed of wood. For a case that will require a shade 12 or 15 inches in diameter, take three pieces of plank—walnut or other hard wood—2 inches thick, fasten them securely together with glue and screws, forming a solid piece of wood 6 inches thick. The inside of this piece of solid wood is to be removed by the saw, leaving only a rim to support the zinc pan, which is to contain the soil. This wooden rim, which is to be turned in finishing, can be ornamented if you wish. The case when complete will last for years. The heat and dampness will not affect it provided no water is thrown over it. A zinc pan, with an opening in the bottom for drainage, fits into the wooden case. The pan is made with a rim to receive the shade; this will prevent water from coming in contact with the wood. This wooden case will cost about double the price of one made of earthen or lava ware; but it presents a better appearance in the room, and there is no trouble from scaling-off or cracking, as is often the case with earthenware. Very few of the latter are properly constructed for drainage, therefore I would recommend a wooden case. The larger the case the more satisfactory it will be. Frequently in selecting a case one has to be guided by the space he can afford for it; but I should say the larger the case the better. I have had cases no larger than 4 inches in diameter, but of course they were mere toys, though better than none if you have space for one no larger.

If you have a wooden case designed for a shade 15 inches in diameter make it 6 inches deep. This will give you 2 inches of drainage and 4 inches of soil, in which can be grown any plants suitable for a case of this size. Most of the earthen Fern cases are not more than 4 inches deep; this depth will answer for those of small size, but it is not sufficient for larger cases. The soil and method of planting recommended for Wardian cases are suitable for ferneries, also the same general treatment will answer for a ventilated Fern case.

A Fern case for winter decoration ought to be filled in August, or not later than the 1st of September. This will give the plants time to get fairly established and make new growth for the winter before the short cold days commence. Cases filled later in the autumn afford very little satisfaction or pleasure, as they rarely get underway or begin to make new growth until spring, if they do not wholly die out during the winter. Were I intending to fill a case for my own use I should certainly plant early.

For the close case I should only use such plants as are suitable. Disturb the shade only when water is required, or signs of mould are visible, or the plants damp off; then give air for a short time each day, wiping out the glass when it is removed. This will generally remedy the trouble when practised a few times. When the plants are in vigorous growth and during the warm weather give considerable water, but withhold it almost entirely during the winter, and give plenty of light at all times.—W. H. HALLIDAY.

## NOTES ON VILLA AND SUBURBAN GARDENING.

**KITCHEN GARDEN.**—The first week in August is the time when I like to sow a good breadth of Spinach for autumn and winter use, sowing again for succession early in September. The first sowing if it does well gives a good supply through the autumn and up to Christmas, while the second crop may be expected to stand the winter well and come to perfection as the days lengthen in spring. Spinach grows as fast in the latter part of summer as it does at any time, and if the soil is deep and good, which it ought to be, the leaves come large and fleshy, and the crop is then abundant.

The present is also a capital time to sow a bed of Cabbage seed for the general crop. The Early York is considered a good sort, but Cattell's Reliance is quite as good. There is, however, a sort about here called the Early Rainham, which is much the earliest of the three, and turns in well. I grew all these sorts this season, and they came in good succession. With regard to planting Cabbages after the Onion crop, which some object to on account of the maggot which the Onions leave behind, I should not advise that being done where the Onions are at all affected; but if they are free from that enemy there need be no fear of the Cabbages not doing well. I like to manure the ground and dig it deeply and work the soil down as much as possible, putting the plants out immediately. The ground from which Peas have been taken will do for Cabbages if the other fails, and, if the Pea ground is not wanted, for late crops of Celery.

I perceive the Potato crop is dying off, and on examination find the tubers are almost ripe. I quite agree with what Mr. Luckhurst says about taking them up. I have my early Potatoes already up, and the others if left in the ground will start into growth again if wet should come on. We have had no rain here for many weeks, and most of the tubers are small. No doubt this will be a season favourable to such sorts as Sutton's Flourball and many other coarse-growing sorts, which will probably prove better in flavour than usual. This "curl" or whatever disease it is, has confined itself to the American Rose, and the haulm has been dead for a long time, and those affected have no tubers larger than walnuts.

Late Celery may still be planted as ground becomes vacant. Probably in such a season as this the latest-planted rows will prove as good as the others, for lately Celery has not grown owing to the excessive heat and drought. If rain comes lose no time in planting Savoy, Broccoli, and Kale of different kinds; also Coleworts and Lettuces should be planted in large quantities, as they are now safe from running to seed. It will be best to sow often, so as to obtain a good stock of plants for the autumn.

Attend to Tomatoes frequently by stopping the young growths and not allowing the plants to grow more fruit than is at present swelling-off, as there will not be time for it to ripen, and it will impair the quality of that which set first. The plants must have manure water frequently, for being grown against walls evaporation is excessive, and the plants being fast growers much water is needed to keep them in a healthy state.

**FRUIT GARDEN.**—Strawberries must now be attended to, both for forcing and new plantations. I make a new bed every third year. I should do so often, but have not the ground to spare. Let the runners that were first layered be taken from the parent plants, and in a few days afterwards be potted into larger pots and placed on a bed of ashes in a convenient place for watering, for they will need copious supplies. Later runners should be cut off when ready, and after the pots are filled with roots they should be planted-out without delay, for the earlier they are planted the stronger the plants become before winter, and the better they may be expected to fruit next year. A piece of ground should be trenched-up for them, and rich manure should be added freely and mixed with the soil. This may be suppl-

mented by surface-dressings and by liquid manure when the plants are established.

Do not neglect the nailing-in of young wood of wall trees, and cut away all those lateral shoots which come from the wood made early in the season. These late growths will not ripen if left, and as a rule such wood is not fruitful. In going over them it is advisable to remove much of the wood not likely to be wanted another season; but do not be too severe on this point, because in spring pruning it is always best to have a choice of wood for fruiting.—T. RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

We are passing through a period of the most unfavourable weather experienced for many years: all the crops are suffering to an alarming extent, and in the course of the next few weeks if no rain falls we shall be almost without vegetables. If we had the means of deluging the crops with water it would not be so, but this cannot be done, and the crops will not live through the drought. Even the fruit trees that have been established for years are drooping for lack of the necessary moisture, but they are not at the same time suffering from an overcrop of fruit. Plums are almost nil; Apples and Pears being few and far between.

Such weather is very favourable for the destruction of weeds, and the hoe should be kept at work wherever practicable; but however well the ground may have been hoed a few weeds will remain—they may be seen, tall strong plants, hardy, and full of ripe or ripening seeds. Amongst Potatoes almost ready to be dug up, or amongst other permanent crops, a boy in a few hours with a basket or wheelbarrow could clear a large garden of such weeds and prevent their seeding, saving much trouble next year. The walks should be kept clear of weeds, and they should, if possible, be swept once a week, and be rolled occasionally.

As Peas and Potatoes are cleared from the ground it is being prepared for hardy Greens, Coleworts, and sprouting Broccoli. The plants look fairly well as yet, and if we have a good shower of rain they will soon start into growth. We shall also prepare ground for the winter Onions by digging it deeply and manuring well. A border of well-trenched and manured ground ought also to be prepared for winter Spinach. It must be sown immediately. Lettuce may also be sown in a shady place, and other small salads as they are required.

### PINES.

There are plenty of strong suckers ready to be potted, and they will be done if possible this week. The fruit has all been cut, and when this is the case the suckers can easily be wrenched out by the hand; the ragged end of the sucker is then cut clean across with a sharp knife. The bottom leaves should be removed, which will show the young roots just starting. Our suckers are large enough to be potted into 7 and 8-inch pots, and these they will well fill with roots by October. The best potting material is turfy loam, more of what is termed clayey loam than sandy loam (we would rather it was too heavy than too light), about one-sixth part of decayed manure, and a 9-inch potful of crushed bones to each barrowload, and if charcoal is at hand a few lumps may be added to each pot. The drainage should be placed carefully in the bottom of the pot, and the compost should also be rammed in quite firmly with a wooden rammer. The tan should be renewed either by having the old material removed altogether, or it should be passed through a sieve, the finer portion to be taken away, and the rough part to be mixed with fresh tan. It will be found that the temperature of the bed after this will rise to 110° or even 120°, but it is not nearly so hot as this a few inches below the surface, and the pots may be plunged to two-thirds of their depth, the brisk bottom heat will cause the roots to form quickly. If the potting material is sufficiently moist at the time of potting it will be better not to water the plants for a few days or even a week if the weather is dull and cold. The succession plants that have been removed to the fruiting house will not be subjected to a higher bottom heat than 90°. Houses where the fruit is ripe and ripening should be aired freely; indeed, the ventilators may be open night and day, and the atmosphere may be kept rather dry.

### ORCHARD HOUSE.

The fruit is now ripening, and this necessitates a much drier atmosphere; and the trees whereon the fruit is ripe, or nearly so must not be syringed at all, nor must the supply to the roots be as abundant as heretofore. It will be seen from this how necessary it is to have the trees quite free from insect pests before the ripening period draws near. It is not possible to syringe at all when the fruit is generally ripe. The first to ripen was the Early Rivers Peach; this and the other early sorts raised at Sawbridgeworth are very useful for their earliness if the quality was good, but this year, although there was a fair crop on the tree, nearly all the fruit had split stones, and none of it was presentable on the table in the dining-room. Others may have

had a different experience; ours has been unfavourable to this sort for the last six or eight years at least. With it ripens the Beurré Giffard Pear. This is by far the best of the early sorts, and though rather later than Doyenné d'Été it is very much superior to it in every respect; it makes a very acceptable addition to the dessert at this early season. Early York Peach will be ripe in a week. This variety is invariably good, and a most free-bearing sort as well; it is generally three weeks later than Early Rivers. Before they are over the Royal George and other midseason sorts come in with Hunt's Tawny and Lord Napier Nectarines. This last-named variety is another of the Sawbridgeworth introductions; it is said to be a sport from Early Alfred Peach. It is a most excellent Nectarine, full size, nearly as early as Hunt's, and far superior to it in flavour. We shall have to discontinue syringing in a week or ten days, but the trees are healthy and free from red spider.

*Figs in pots* that are now bearing ripe fruit require similar treatment to the orchard-house trees. There is no necessity for any artificial heat, and the atmosphere of the house ought to be moderately dry. No syringing of trees is permitted at this time, but it ought to have been well carried out up to the time of the first fruit ripening. Like the Peach the Fig is liable to be attacked by red spider, and if this pest is abundant on the leaves the flavour of the fruit is very much deteriorated. Less water is required at the roots, but the plants must not suffer for want of it. Young plants that are being grown-on should be freely syringed, and the house ought to be closed in the afternoon, syringing the Fig trees at the same time.

### GREENHOUSE AND CONSERVATORY.

The more hardy of the hardwooded greenhouse plants have been turned out of doors, and Azaleas of large size that have now set their buds in the forcing house will be gradually inured to a cooler atmosphere, and will also be placed outside for a short period. The plants must be placed either on a bed of ashes through which no worms can find their way; or, what is better, if the pots are above 18 inches in diameter three bricks should be laid flat on the ground, on which to place the pots. The centre hole is in this way raised 2 inches or more from the ground, and we believe that the air being allowed underneath the pot is good for the health of the plants. The sun ought not to be allowed to shine directly upon the pots; if it does the small rootlets, which are most active and numerous between the sides of the pots and the soil, will most likely be killed. To prevent this some roofing tiles, slates, or boards may be placed against the pots on the sunny side. When the pots are upon bricks they are more easily blown over by the wind than those standing upon the ground; and to prevent this three stout sticks should be driven into the ground round the pot, and to them the pot should be fastened with strong tar string. All plants, including Azaleas, that are subject to the attacks of red spider should be smartly syringed, working the water under the leaves. In hot seasons Camellias become disfigured by red spider attacking the leaves, but this plant delights in frequent syringings; so that if the leaves are browned by red spider it must be attributed to neglect.

### FLOWER GARDEN.

We cannot say much for the beauty of the bedding plants this year. Even zonal Pelargoniums, which flower most freely in hot seasons, have had almost too much of an East Indian temperature; the rich crimson scarlet of Wellington has had the colour bleached, and is true to itself only when the plants are shaded from the noonday sun. Verbenas have had no chance to start into growth, and a favourite bed that is annually planted with Mangles' Variegated Geranium and Purple King Verbena has not yet covered the ground. The Silver Variegated section of Pelargoniums are doing better than any other sort; the proportion of white is larger than usual and is very pure. Asters have not done so well as they ought, considering the care that was taken of them early in the year. Green fly made an attack upon them and the plants were overlooked for a few days, but the pest left its mark upon the plants. They are now clean and growing freely. Roses have flowered very well, and have been very free from insect pests; even the bud worm did not do as much damage as usual to the young shoots. All the flowers are removed when the petals are ready to fall. By going over the plants frequently and picking off these and the seed pods the bushes have a more tidy appearance.

Pipings of Pinks have been put in. We like to do this in wet weather, the best strike is obtained at such a time. This has not been possible this year, but the beds were well watered before the pipings were taken from the plants. They were put into boxes, which were placed in a frame behind a north wall. The best blooms of Carnations and Picotees are over, and we are now busy layering the grass; by the time this is in the printer's hands most of them will be finished. The wind is high, which is not in their favour, as many of them are broken by it; this is owing to the notch in the stem being cut too deep. Auriculas require looking over once a week to remove decaying leaves and green fly. Hollyhocks and Dahlias must be fastened to sticks as they grow. If Dahlia shoots hang loose

they are very easily injured by high winds. Phloxes are now in full bloom, and well do they repay the little attention they have received as to tying them to sticks and watering. The Phlox suffers much if the roots are dry; it requires abundant supplies of water.—J. DOUGLAS.

## HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

LONDON RINK, CAMBERWELL NEW ROAD STATION. August 3rd, 4th, and 5th.

RAWNSTALL (ROSENDALE). August 4th and 5th. Mr. M. J. Lonsdale, Sec. SOUTHAMPTON. August 5th and 7th. Mr. C. S. Fridge, 39, York Street, Sec.

FINEDON. August 7th. Mr. G. C. Mann, Sec.

TAUNTON DEANE. August 10th. Mr. F. H. Woodforde, M.D., and Mr. Clement Smith, Hon. Secs.

FILEY. August 11th. Mr. Walter Fisher, Hon. Sec.

OTLEY. August 12th. Mr. Alfred Suttle, Hon. Sec.

CLAY CROSS. August 15th. Mr. J. Stallard, Clay Cross, near Chesterfield, Sec.

EMSWORTH. August 15th. Mr. H. Moore, Hon. Sec.

WESTON-SUPER-MARE. August 15th and 16th. Mr. W. B. Frampton, Sec.

PRESTON. August 16th and 17th. Mr. W. Troughton, Hon. Sec.

SHERWSBURY. August 16th and 17th. Adnitt & Naunton, Hon. Secs.

LEDBURY. August 17th. Mr. J. B. Masefield, Hon. Sec.

NORTON, NEAR STOCKTON-ON-TEES. August 18th. Mr. C. Turner, Sec.

MIRFIELD. August 19th. Mr. G. Senior and Mr. J. Rushforth, Hon. Secs.

CALNE (Wilts). August 22nd. Mr. H. Blackford, Sec.

NEWBURY. August 22nd. Mr. H. Seymour, Hon. Sec.

DORSET COUNTY. August 23rd (at Dorchester). Mr. A. Pope and Mr. C. Parsons, Secs.

CHESTWOT. August 23rd. Mr. R. Thorn, Hon. Sec.

CARSHALTON, WALLINGTON, and BEDDINGTON. August 24th. Mr. J. Baines, Leicester House, Carshalton, and Mr. W. Clark, the Nurseries, Wallington, Hon. Secs.

LARGS and FAIRLIE. August 25th. Mr. D. G. Glen, Hon. Sec.

SEATON BURN. August 26th. Mr. B. Richardson and Mr. W. Elliott, Secs.

ISLE OF THANET (MARGATE). August 30th. Mr. C. D. Smith, 8, Marine Terrace, Margate, Sec.

POCKLINGTON. August 31st. Sec., Mr. J. E. Ross.

YARMOUTH. August 31st. Mr. S. Aldred, Hon. Sec.

THORNTON HEATH. September 1st and 2nd. Mr. W. Raines, 10, St. John's

Villas, Bensham Manor Road, Thornton Heath, Hon. Sec.

MONTROSE. September 1st and 2nd. Mr. Alex. Burnett, 2, High Street, Sec.

DUNDEE (International). September 7th, 8th, and 9th. Mr. W. R. McKelvie,

26, Euclid Crescent, Sec.

GLASGOW. September 12th and 13th. Mr. F. Gilb. Doughall, 167, Canning

Street, Sec.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY. September 13th.

KILMARNOCK. September 14th. Mr. M. Smith, 11, King Street, Sec.

IPSWICH. September 17th. Sec., Mr. W. B. Jeffries, Henley Road, Ipswich.

NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W.

Gutteridge, 51, Denmark Road, Northampton, Sec.

## TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*Agricultural*).—No book gives the synonyms of kitchen garden varieties. Paxton's "Botanical Dictionary" would aid you in other ways.

BOOKS ABOUT GRASSES (*W. E. L.*).—Scheuchzer's "Agrostographia," in Latin; and in English Sinclair's "Hortus Gramineus Woburnensis" and Lawson's "Agrostographia." We cannot name so many specimens.

LILY OF THE VALLEY (*F. S. T.*).—The leaves ought not to be cut off so long as they continue green. Any that become decayed may be picked off.

WILD FLOWERS (*Mrs. Otter*).—The work is not yet completed.

EXHIBITORS' GRIEVANCES (*D. R. & Co.*).—We can only recommend the Royal Botanic Society to be more liberal, for if they are not their shows must be injured.

CARNATION AND PINK SHOWING (*H. E. C.*).—These flowers are rarely ever shown without cards, and if the petals are simply arranged and none added they cannot fairly be disqualified—*i.e.*, provided the pods are not split.

GARDENERS' BENEVOLENT SOCIETY (*A. W.*).—Write to Mr. Cutler, Secretary, Gardeners' Benevolent Society, York Street, Covent Garden, London.

PERPETUAL ROSES FROM CUTTINGS (*Wilts*).—Cuttings may now be taken off such shoots as have just shed the flowers, such shoots being in the proper order for propagation, the wood being ripe. The cuttings may have three joints, cutting transversely just below the lowest joint and removing its leaf, the other leaves being left intact. The cuttings may be inserted an inch to 1½ inch in small pots in fibrous loam and sand in equal parts. Two joints will answer for the cuttings, but it is important that the cutting have at least one leaf attached. The pots may be plunged in a hotbed in tan or sawdust, the bottom heat of the bed at the bottom of the pots being 75°. They will need to have the lights of the frame kept perfectly close, and the cuttings sprinkled overhead every morning lightly, and shaded from sun. In about a fortnight they will have rooted, but they must not have air or be removed till shoots are made 1 to 2 inches in length. After this air may be gradually

admitted, the plants by degrees being inured to light and air. They should be moved into larger pots—¾ to 5 inches, continuing in the frame until established, but with moderate air only for a time. Afterwards harden well off and plunge outdoors in ashes in an open yet warm situation. The cuttings may, instead of being placed in heat, be placed in a cold frame kept close, shaded, and sprinkled every morning, treating in other respects as before stated. They will root more slowly, but not less surely in the cold frame than in a hotbed.

MELONS CRACKING (*C. R.*).—Cracking arises from the supply of sap being too liberal after the fruit has commenced ripening, and is usually most prevalent when the growth of the fruit has been made under very bright sun, the ripening taking place with too much moisture in the atmosphere. Kinds liable to crack—most of those with hard rinds and much netted—we usually cut the vine carrying the fruit about halfway through when the fruit is full-sized, and increase the cut in a few days to three parts the thickness of the stem, keeping the soil and atmosphere dry. The scarlet-fleshed kinds as a rule are more liable to crack than the green-fleshed or white-fleshed, but with proper moisture during the swelling of the fruit, and dryness when ripening, cracking does not occur in any.

LETTUCES RUNNING (*F. W.*).—Your Lettuces run because their sowings are made too distantly, the plants being sown too thickly, or left to grow too long before thinning, with the soil dry and loose. We sow every fortnight or three weeks from the first week in April to the first week in August where the plants are to remain, the ground being well manured and trod firm as for Onion beds before sowing, and sow in drills a foot apart, and thin out the plants to a foot distance in the rows, and early before the plants are drawn. We never water, and never fail of "big" heads—Cabbages they are termed—from these sowings from June to November inclusive—after December if the weather be mild. Though we grow half a dozen or more sorts, dependance is placed upon Paris White Cos—that fine selection of it known as Alexandra Cos, and Neapolitan Cabbage, the two best summer Lettuces in cultivation. All the Year Round is much esteemed in the kitchen, but is too soft in hot weather for the salad bowl.

STOPPING TOMATOES (*Alex. Boyle*).—You are quite right in your ideas as to stopping—*i.e.*, if you have two or three bunches of fruit showing upon a shoot stop it at or one joint beyond the uppermost show of fruit, taking out the point of the shoot immediately the growing point is clear of the joint having the fruit. The side shoots we should stop immediately you can beyond the first truss of fruit. We prefer to go a joint past rather than stop at the same joint as that the fruit is situated at, and with these it is likely you will have as much fruit as will ripen; nevertheless keep on stopping beyond each show of fruit—preventing overcropping, much being done in that way by removal of the old useless leaves.

APHREXIS DYING (*Amateur*).—The watering "with a mixture of cow dung and soot cleared with lime" is sufficient to account for the death of the plants. You will not find any such instructions in our "Greenhouse Manual." Avoid lime for all plants requiring peat soil, and as a rule liquid manure for most hardwooded plants. The plants appear to have been too liberally watered for recently-potted plants. We do not know a book treating of New Holland plants. Sufficient instructions are given in the "Greenhouse Manual," which we must remind you has not been followed, but deviated from with disastrous results.

SALISBURY ADIANTIFOLIA PROPAGATION (*S. M. W.*).—Layering is the most certain mode, it being done in autumn or spring, the layers not unfrequently requiring two years to root, but if kept moist they will root the first year. Cuttings of the well-ripened shoots with a heel of last year's wood inserted under a hand-lift in a sheltered situation in September.

PHLOXES FRUTICOSA PROPAGATION (*O. W. D.*).—It is a low-growing shrubby plant, requiring a warm situation and a well-drained soil, and moderately rich. Cuttings or slips inserted now in a shady border, or better under a hand-glass, shading from bright sun; seeds, which you may save, sown in early April in a warm border in light sandy soil. The plants from seed are best, though those from cuttings flower earlier.

CUCUMBERS SWELLING IRREGULARLY (*Subscriber since 1856*).—The plants are affected with gangrene, a result usually of the roots being in too rich soil, too wet, and cold. A little increase of bottom heat would induce more regular swelling, affording moderate moisture, too much probably arising from the tank, making the soil sour. A brisker heat with freer ventilation should give you healthier growth, and with that you will have better-swelled fruit.

CYTISUS, CALLA, AND DOUBLE PRIMULA CULTURE (*Lancastrian*).—The Cytisus we should at once shift into a pot that will admit of an inch of fresh soil all around; the plants being turned out of the pot, remove the old drainage and loosen the sides of the ball with a pointed piece of wood, potting rather firmly, and keeping the collar of the plant slightly raised in the centre of the pot, employing a compost of three parts fibrous loam, one part leaf soil, and a free admixture—about a sixth—of sand, providing good drainage. *Richardia* (*Calla*) *ethiopica* we should now repot, removing most of the soil from the roots; in fact, all coming away freely should be removed, and the plant returned to the same size of pot, or one that will hold the roots and admit of fresh soil amongst and around them, potting moderately firm, using turfy loam, with a fourth of dry cow dung or well-decayed manure added. Place outdoors on ashes and keep moist, and by the close of August fresh growth will appear, removing to a light airy position in the greenhouse at the close of September, and in early October shift into a pot 4 inches larger in diameter, keeping duly supplied with water, and in spring water liberally. The double *Primulas* should be kept in the greenhouse or in a pit or frame rather dry until the early part of this month, when they should be repotted, loosening the sides of the ball a little, and shifting into a slightly larger size of pot. A compost of fibrous loam and sandy peat in equal parts, with a fourth of leaf soil and a half part each of silver sand and pieces of charcoal, well mixed and moderately firmed in potting, providing good drainage. Water carefully, especially during winter.

ZONAL PELARGONIUMS FOR EXHIBITION (*Zonal*).—As there are two classes in the schedule—one for zonal *Pelargoniums* and the other for the section named "nosegay," it would be wrong to show the ordinary or florists' type in the nosegay class; the collection would most likely be disqualified. Any variety with a plain leaf would be distinguished by its flower: if it had a nosegay flower it would be exhibited in that class, and *vice versa*. It cannot be the desire of the committee to exclude plain-leaved sorts from the zonal class. As to distinguishing an ordinary florist variety from a nosegay, they have been so intermixed that it is difficult to say where the one leaves off and the other begins. *Stella*, *Cybister*, *Lord Palmerston*, *Amy Hogg*, and all the varieties with large trusses and narrow petals are the true nosegays. Well-

ton, sent out by Mr. W. Paul, is a cross between a nosegay and a florist variety; it has the large truss of the nosegay, and ought to be eligible for that class.

**WINTERING MESEMBRYANTHEMUM CORDIFOLIUM (Franklin).**—You may winter it quite safely in a greenhouse from which frost is excluded, only do not water more than to keep from flagging. The Coleus you would lose from cold and damp, it requiring a temperature of 50° to winter safely.

**IRIS SUSIANA AND I. IBERICA CULTURE (Idem).**—Place them outdoors, or better plunge in ashes in an open situation, and they will not require further attention until late in September, when they may be removed to a cold pit, and be kept rather dry there or in a cool part of the greenhouse until spring, when they should have water as the growth advances and proportionate fertilizer. Repot in early spring, adding a third of peat to the loam, with a free admixture of sand.

**GREEN SPOT FROM MANGLES' VARIEGATED GERANIUM (Mars).**—This is not unusual; we counted three green spots on one bed after receiving your letter. *Clorodendron Balfourii* ripening seeds is also a common occurrence.

**MANURING STRAWBERRY BEDS (A Subscriber).**—This may be done in November, or any time through the winter. The manure ought to be applied before the plants start in the spring.

**GRAPES MILDEWED (Tyro).**—We have had to do with vineries of all sorts for many years, and have had the Vines attacked by mildew, but never to the extent of requiring the bunches to be powdered with flowers of sulphur to destroy the mildew. On the first appearance of the parasite you should coat the hot-water pipes with sulphur worked into a paste. Apply it with a painter's brush. The pipes should be made so hot that the hand can just be held on them. Any seedsmen can supply you with an appliance for dusting the sulphur amongst the berries. If yours are very bad it may be necessary to do this.

**MORELLO CHERRY ON CLAY SOIL (H. T. Z.).**—We find that this Cherry succeeds better on a light soil or medium than on a heavy clay. You should try working some leaf soil, sand, or road scrapings amongst your clay soil.

**CULTURE OF POMEGRANATES IN POTS (M. E. T.).**—First, the soil should be turfy loam with leaf mould and a little rotted manure. Second, repot in November or December. If the plants are small, once a year; if large, every second year. Third, the points of the young wood ought to be cut-back in winter, and the temperature should be very low. It is not safe to place the trees out of doors before the danger from frosts or cutting winds are over in the spring; the young shoots are easily injured.

**LEAVES OF PEACH TREE DROPPING (E. S.).**—It is difficult to say what may be the reason of this. A quantity of soft-soapy water would injure the roots, and Noblesse would suffer either from this or drought before Barrington. We rather think it must be the drought. Water well and mulch with manure. If drought is the cause of the injury many of the small roots will be dead, and the tree will not recover all at once.

**THRIPS ON VINES (W. Hay).**—We were much troubled with this pest in our vineries some years ago, and could only destroy the insects by fumigating with tobacco smoke, but this caused the fruit to taste slightly of tobacco. In the autumn the Vines should be well washed with a strong solution of soapy water, tobacco liquor, and flowers of sulphur after removing all the loose bark.

**HARDY SUCCULENT PLANTS FOR EDGINGS (S. J. P.).**—*Sempervivum californicum* planted 6 inches apart, and the interspaces planted with *Sedum glaucum*, forms a chaste, beautiful, and permanent edging for flower beds, both plants being perfectly hardy.

**EARLY PEAS (F. W. L.).**—If you procure Carter's First Crop true to name you will find it earlier, also dwarfier, than Sangster's No. 1. Both are useful early Peas. If you add to them William I. and Alpha you will have Peas both early and of good quality.

**AMERICAN BLACKBERRY PLANTS (H. C.).**—Write to a nurseryman at New York.

**SEEDLING GERANIUMS (Amateur Gardener).**—They are not in any respect equal to many others.

**CUCUMBERS DISEASED (C. M. M.).**—Judging by the fruits sent your plants must be in a deplorable state. If there are ulcerations and exudations of sap from the stems you have the "Cucumber disease" which you will not be able to cure this season, but you may, perhaps, prevent it the next. If, on the other hand, the fruits only are affected, the stems not being ulcerated, the injury arises from insufficient temperature and perhaps a cold and stagnant soil. Cut off all the affected fruits, all bad leaves and weak growths, and remove carefully a portion of the soil, adding fresh; increase the temperature of the soil and atmosphere, and with careful waterings with tepid water, and judicious ventilation your plants may start into fresh growth and produce clean fruits. The minimum night temperature should not be lower than 65°, but 70° would be preferable for a time to assist the plants to make fresh growth quickly.

**BLECHNUM, &C. (G. M.).**—Not knowing where or in what soil the plants are grown we cannot advise you, nor can we name a Fern from a scrap of a frond.

**SULPHUR ON GRAPES (J. E.).**—As it has effected its purpose and the berries are green you may syringe it off.

**CULTURE OF CHILIES (J. N.).**—The seeds, which may be kept in their ripe cases until wanted, should be sown under glass towards the end of March in a very rich soil, and if in a hotbed all the better. As soon as the plants are 4 inches high they should be pricked-off, either singly in small pots or four in a 5-inch pot, and well watered, syringed, and smoked to destroy the green fly, and shifted again if necessary until the first or second week in June, when the plants may be turned out into nice mellow soil in front of a south wall, in front of forcing houses, or on a south border, when a good quantity of green fruit will be obtained in September and October. If by the middle of September they should not have produced ripe fruit enough take them up with a ball of earth, repot them, shade them in a frame, pit, or hot-house of any kind for a few days, and keep them under glass. They will hardly feel the moving, and will produce abundance of either green or ripe fruit, whichever may be most required for use, all winter and next spring.

**NAMES OF FERNS—CYRTOMIUM FALCATUM (B. H. H.).**—No. 1, *Lastrea Filix-mas*; 2, *Adiantum trapeziforme*; 3, *Lastrea acuminata*. *Cyrtomium (Aspidium) falcatum* is hardy in warm localities and sheltered situations, but is more generally desirable for greenhouse. In cold localities it is not hardy. It is a native of China and Japan.

**SOOT WATER FOR VINES (D. P. B.).**—About thirty gallons of water to each

peck of soot will be the right quantity. It is best to place the water in the tub and suspend the soot in it in a coarse bag for a few days. You will then obtain a clear solution of sufficient strength for your purpose.

**NAMES OF FRUITS (R. L.).**—Your Pear is *Doyenné d'Été*, or Summer Doyenné.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### POULTRY AND BEE NEWS AND QUERIES.

We have been often asked for reliable information about the success of eggs sent to and from America for hatching purposes. We are able to reply fully to the query, and will give particulars of a package coming from and going to America. In the latter part of April Mr. Norwood of Salisbury sent Mr. G. Brown of Brooklandville, U.S.A., twenty-six White-crested Black Poland eggs. They were packed in a substantially made box of inch deal, and the package measured 12 inches each way. The eggs were packed in dried peashells and bran, and out of the twenty-six eggs twelve strong chickens hatched out, two more having died in the shells; the other twelve eggs were clear. On June 3rd Mr. Norwood received from Mr. Brown thirty-one White Leghorn eggs. They came to him packed in the same box as he had used in sending the eggs to Mr. Brown. The cost of the package from Brooklandville to Salisbury station was 14s. 2d. The eggs hatched in twenty days, and from them there were twelve chickens hatched alive, seven died in the shells, three eggs met with accidents, and nine were clear. We have heard of better hatches from American eggs and from English eggs sent to America, and we have known of many less successful ventures.

The Portsmouth Poultry Show was held on June 21st and two following days—very nearly six weeks ago, and we read in the schedule in large type that "all prizes will be paid within fourteen days from the close of the Show." We know of prizes which up to now (July 31st) have not been paid. It is also stated in the schedule that successful exhibitors could on application at the office receive their prize money on any day of the Show. We heard one well-known exhibitor apply for his money, and he was told by the Secretary that the Committee had not furnished him with any funds wherewith to pay such prize money. We know these facts have been freely commented on, and we fear the Ornithological and Zoological Society of Portsmouth will gain no advantage from the discussion.

Among the schedules which come to us is one from Weymouth. In many ways it is good; but we think here, as too at Rochdale, the difference in the value in the first and second prizes—30s. and 10s.—quite ridiculous. If only 40s. could be afforded for the two prizes, 25s. and 15s. would have made a much better proportion. At Weymouth, too, there is no Variety class, while French have three classes, one being for Houdans, one for Crêves, and the other for any other variety of French. They may get a brace of pens of La Flèche, but we should imagine it was very doubtful. As we have before stated, we cannot afford space to criticise every schedule, and so only from time to time are able to pick out the salient points in any Society's prospectus. Bath has issued a capital schedule, and the neglected breeds can here have a merry time, for there are classes for Malays, Minorcas, Leghorns White and Leghorns Brown, Silkies, and Black East Indian Ducks. We regret that Bath and Southport should clash, for the latter's prize list is very good. In it we see Dorkings have seven classes, Cochins eight, Hamburgs ten, while all breeds seem handsomely provided for.

We fear there is still the disposition among many committees not to publish the names of the judges at their shows. Our own views are well known on the subject, so we need not return to them. We would only again beg committees and secretaries to understand that if once a judge is mean enough to co-operate with any exhibitor, that judge is just as able to write and tell his colleague that he is judging at any show, when the said friend would of course enter, while the entries are lost of those exhibitors who will not enter unless they know the judge's name and capabilities. Under this latter head, however, there is frequently some favoritism shown by secretaries, for at a show held in June last we know of one poultry exhibitor who said he would enter largely if the judge's name was revealed; this was done to him in confidence, while several others who were smaller exhibitors had the intelligence refused to them. We ask if this is more satisfactory a line of proceeding than publishing the judge's name, when all fanciers would be able to stand the same chance.

At several recent poultry shows held in consecutive order all the prizes in Poland were taken by the White-crested variety, and this with capital specimens of the other colours in the classes. This would seem as if the breed was becoming much more cultivated; and it being one of the most beautiful breeds we have we are glad of it, and would recommend energetic

committees to give these birds more classes and so push them still further.—W.

### BRAMLEY SHOW OF POULTRY, &c.

THE annual Show of this thriving Society was held on the 24th and 25th ult., when the weather presented quite a contrast to that of last year, when the show field was like a bog and everything half drowned, and which caused a great loss to the Society. A capital marquee was provided for the poultry, &c., and this proved a welcome protection from the scorching sun. Turner's pens were used, and were well arranged for seeing. Poultry were a little smaller show, Pigeons large, Rabbits the very best held by this or any other society for the amount offered, but Cage Birds a failure in numbers.

*Spanish* were a good class, and *Cochins* a fair lot; but the best pen in these varieties was the first-prize *Brahmas*, but only the winners in *Polish*, *Game*, and *Hamburghs* were good in these classes. *Bantams* had well-filled classes, the first in *Game* Black Reds, and second *Brown Red* chickens. Two classes of chickens were provided; the best in these were the first-prize *Brown Red Game Bantams*.

In *Pigeons* the competition was very keen, Messrs. Baker, Harvey, and Yardley being among the competitors. Carriers a grand class. First the well-known *Palace Black* cock; second, a capital *Black*; and third a promising young bird not made-up. Pouters, a charming *Blue* hen first; second a *Black*, faulty only in colour, but in grand show; and third a *Blue* cock not quite in condition. Trumpeters mostly Mottles and very good. Tumblers all noticed, and a splendid lot. First an *Almond* cock of high quality of head and thoroughly broken in feather; second a *Kite*; and third an *Agate*. Barbs very good and all *Black*. In *English Owls* five of the best were left out, the exhibitor's man not having removed the zinc labels from their feet. First a grand *Blue*; second *Blue*; third *Silver*. A large and good class. *Dragoons* a good class, the winners stood well out, first *Blue*; second *Silver*; and third *Red*, an exquisite bird but out of feather. *Jacobins*, winners *Red* and all of high quality. *Fantails* a nice lot. In *Turbits*, first a sound-coloured *Blue*, second *Yellow*, a little coarse; and third *Silver*, which was a little too Owl-like in head. Common Tumblers, *Bald* or *Beard*, very good, first *Black*; second *Blue* *Bald*; and third *Yellow* *Beard*. Any other Tumbler, not so good. In *Magpie* or *Swallow* the former won all the prizes. A *White* foreign Owl of grand head properties was first in the variety class, second a *Blondinette*, and third an *Ice*. *Antwerps* were a very good entry, and some strong likely birds put in an appearance. In *Short-faces* the winners were all *Silver* Duns, and in *Long* first and second were *Red Chequers*. Among the *Medium-faced* birds were some grand birds, the first a *Silver* Dun being very handsome, the second a *Silver*, the third *Blue Chequer*. Two classes were provided for hens—viz., one for *Short*, the other for any other variety, and in the former first was a *Short-faced*, a splendid bird; second a *Blue Chequer*, a little lost in beak; third a *Red*. The *Flying* classes and *Selling* classes were large, but of little note except the winner.

*Rabbits* had 125 entries in nine classes, and these were well bedded and cared for. The Judge's name had been advertised, a point we have contended for for a dozen years at least, and yet this seems to have been no safeguard against the libellous conduct of a certain clique, some of these gentlemen carrying their virulence so far as to attempt a stab in the dark by writing privately to the Secretary of the Show, while another exhibitor sent to the Judge a few days before the Show a basket of edibles, which were turned over to the Secretary for the use of the Committee, who no doubt enjoyed it immensely. In *Self-coloured* Lops, first was a large, good-styled *Sooty-fawn* buck rather out of down, second a *Fawn* buck not so good in leg, and third a nice *Fawn* doe. *Broken-coloured*, first a *Black-and-white* doe, this winning the extra also; second an exceeding nice *Fawn-and-white*, third a *Black-and-white*, but not so good in colour. These were judged for all properties and not for the length of ear alone. *Silver-Greys* were a capital class of seventeen entries, and the competition was very close. First and extra a large young buck very sharp in silvery but slightly dark on nose; second an equally large doe but overfed and some down off the back through accident, but in other respects the best; and third a very promising young one, several very highly commended being almost as good. *Himalayans* very poor except the winners, and these were properly placed, although the second-prize winner states in his report in a contemporary that he should have been first. *Angora* a grand class, but not one of the largest *Rabbits*, has much wool on the back though very good in other respects. First was a young one excessively long and fine in wool, small in ear, and neat in all points; second equally good, and the same class of *Rabbit* a little matted on the side; third large but thin of wool on the back. The extra was awarded here. *Dutch* a moderate lot, first a *Grey* very even but too little marking on face; second *Black*, little short of first; and third *Blue*, but rather uneven on one hind foot; highly commended *Grey*, young and good but a little uneven on

hind feet. *Belgians* a grand class, first a perfect one; second a doe as good but somewhat dappled; and third very similar. In the variety class first and extra was awarded to a *Silver Cream*, a most perfect *Rabbit*; second a *Patagonian*; and third a *Silver Cream*. The *Selling* class contained some good Lops and *Silver-Greys*, first a *Black Lop*, second a *Fawn-and-white*, third a *Silver-Grey*.

### SALTAIRE POULTRY SHOW.

THE first Show was held at Saltaire on Saturday last. For a few plants and flowers a large marquee was provided; but all live stock had to be shown in the open, and the wind being strong and cold in the early part of the day, the birds seemed to suffer very much, while room could have been found for the whole in the tent along with the flowers.

*Poultry* though very good were not numerous, Mr. Beldon carrying off most of the prizes.

*Pigeons* were a large lot, and among them some good birds. Pouters seemed to be judged mostly by measurement; the first *Blue*, and second *White*. Carriers a fair lot; first and cup for the best pen was a mistake, the second were better; the cock in first pen too broad in skull. *Dragoons* good, and all *Blues*. Tumblers, first *Almonds*, which might have had the cup as the best pen. *Turbits* very good and well placed; but in *English Owls* we preferred the *Silvers* in the second pen. *Antwerps* were well provided for, there being eight classes, in fact this may fairly be called an Antwerp show, and the birds were very good and mostly well placed. In the Variety class first were *Black Barbs*, and second *Frillbacks*.

POULTRY.—*GAME*.—1, J. W. Thornton. 2, H. Beldon. *Duckwings*.—1, H. Beldon. 2, J. W. Thornton. *SPANISH*.—1, J. Thresh. 2, J. Powell. *COCHINS*.—1, H. Beldon. 2, C. Carr. *BEAUMA POOTRAS*.—1, H. Beldon. *POLANDS*.—1 and 2, H. Beldon. *HAMBURGHS*.—*Gold-spangled*.—1 and 2, H. Beldon. *Silver-spangled*.—1 and 2, H. Beldon. *Any other variety*.—1, H. Beldon. 2, J. Preston. *BANTAMS*.—*Grey*.—1 and 2, J. Preston. *Black*.—1, H. Beldon. 2, C. & J. Illingworth. *DUCKS*.—1 and 2, J. Newton. *SELLING CLASS*.—1, J. Heaton. 2, H. Beldon.

*PIGEONS*.—*POUTERS*.—1, W. Harvey. 2, J. E. Crofts. *CARRIERS*.—1, J. W. Sykes. 2, W. Harvey. *DRAGONS*.—1, W. Ward. 2, V. Ratcliffe. *TUMBLERS*.—1, W. Harvey. 2, W. Ellis. *TURBITS*.—1, B. Rawnsley. 2, T. Foster. *OWLS*.—*English*.—1, J. Thresh. 2, W. Ward. *ANTWERPS*.—*Short-faced*.—1, W. Ellis. 2, B. Rawnsley. *Hen*.—1, W. Ellis. 2, T. Foster. *Long-faced*.—1, W. Ellis. 2, W. Ellis. *Hen*.—1, W. Ellis. 2, B. Rawnsley. *Medium-faced*.—1, W. Ellis. 2, W. Ellis. *Hen*.—1 and 2, W. Ellis. *Homing*.—1, B. Rawnsley. 2, W. Ward. *Hen*.—1, B. Rawnsley. 2, W. Ellis. *ANY OTHER VARIETY*.—1, W. Ellis. 2, J. W. Holloway. *SELLING CLASS*.—1, W. Ellis. 2, J. E. Crofts.

The Judges were Messrs. J. Dixon and W. Lund.

### TONG AND DUDLEY HILL SHOW OF POULTRY, &c.

THIS Show, though well managed in most respects, does not seem to make the headway that might be expected, the entries in poultry being very sparse, though some good birds were exhibited.

*Pigeons* were more numerous, and some were moderate classes. The *English Owls* were a grand lot, and several extras were awarded, and the *Antwerps* were very good.

POULTRY.—*SPANISH*.—1, J. Powell. 2, H. Beldon. *COCHIN-CHINA*.—1, W. Mitchell. 2, H. Firth. *GAME*.—*Black-breasted* or *other Red*.—1, H. C. Mason. 2, R. Hemingway. *Duckwinged* or *other Grey* or *Blue*.—1, H. C. Mason. *Black*, *Brassy-winged*, or *Pile*.—1, H. C. Mason. 2, H. Walker. *HAMBURGHS*.—*Golden-spangled*.—1 and 2, H. Beldon. *Silver-spangled*.—1 and 2, H. Beldon. *Golden-pencilled*.—1 and 2, H. Beldon. *Silver-pencilled*.—1 and 2, H. Beldon. *POLISH*.—1 and 2, H. Beldon. *BEAUMA POOTRA*.—1 and 2, W. Schofield. *BANTAMS*.—*Game*.—1 and 2, G. Noble. *Any other variety*.—1 and 2, H. Beldon. *Extra*. 2, C. & J. Illingworth. *ANY BREED*.—*Cock*.—1, J. Powell. 2, H. Beldon. *Hen*.—1, H. Beldon. 2, W. Firth. *GEESSE*.—1, H. Beldon. 2, J. Ward. *DUCKS*.—*Rouen*.—1, J. R. Pollard. 2, J. Ward. *Any other variety*.—1, J. R. Pollard. 2, J. Borth.

*PIGEONS*.—*CARRIER*.—*Cock* or *Hen*.—1, W. Harvey. 2, J. K. Sager. *TURBITS*.—*Cock* or *Hen*.—1 and 2, J. Rawnsley. *TUMBLERS*.—*Cock* or *Hen*.—1 and 2, W. Harvey. *JACOBS*.—*Cock* or *Hen*.—1, W. Harvey. 2, T. Holt. *FANTAILS*.—*Cock* or *Hen*.—1 and 2, J. Walker. *CROPPER* or *POUTER*.—1, W. Harvey. 2, J. Rawnsley. *ANTWERPS*.—*Cock* or *Hen*.—1, J. Holden. 2, J. Cockett. *NUNS*.—*Cock* or *Hen*.—1 and 2, J. Rawnsley. *OWLS*.—*English*.—1 and 2, J. Thresh. 2, Helliwell & Ingham. *Extra*. 2, J. Holden. *ANY OTHER VARIETY*.—1, Helliwell & Ingham. 2, J. Thresh. *Found & Chappel*, W. Harvey. *DRAGONS*.—*Cock* or *Hen*.—1, J. E. Crossley. 2, J. Rawnsley.

*RABBIT*.—*SPANISH*.—*Buck* or *Doe*.—1, A. Hawley. 2, Found & Chappel. *COMMON*.—*Buck* or *Doe*.—1, Scalfie & Pinder. 2, J. Atkinson. *ANY OTHER VARIETY*.—1, S. Ball. 2, Mrs. R. Murgatroyd, Found & Chappel.

JUDGE.—Mr. Cannan, Bradford.

### HUNTINGDONSHIRE AGRICULTURAL SOCIETY'S POULTRY SHOW.

THIS was held at Ramsey on the 26th ult., when the following prizes were awarded.

*PIGEONS*.—*DORKINGS*.—*Donation*, Cup, and 1, F. Parlett. 2, Mrs. Wood. *Chickens*.—1, T. Bryden. 2, C. Turner. *Hen*.—*Prize*, Mrs. Wood. *BEAUMAS*.—*Dark*.—1, Horace Lingwood. 2, J. Long. *Light*.—Cup and 1, M. Leno. 2, Mrs. Peck. *Cock*.—1, Horace Lingwood. *COCHIN-CHINA*.—*Cinnamon* or *Buff*.—1, J. Long. *Any variety*.—Cup and 1, R. P. Percival. 2, Dr. Snell. *GAME*.—*Black-breasted* or *other Reds*.—Cup and 1, S. Matthews. 2, Deacon. *Any other variety*.—1, H. E. Martin. 2, S. Matthew. *Any variety*.—*Cock*.—2, Deacon. *HAMBURGHS*.—*Golden-spangled*.—1, J. Long. 2, S. W. Hallam. *Silver-spangled*.—Cup and 1, J. Long. 2, S. W. Hallam. *Golden-pencilled*.—1, W. W. Tiekner. 2, J. Long. *vic*, S. W. Hallam. *GAME BANTAMS*.—*Black-breasted* or *other Reds*.—1, T. C. Davis. *BANTAMS*.—*Any other variety*.—1, M. Leno.

**SPANISH.**—1, S. W. Hallam. **ANY OTHER VARIETY.**—1, J. Long. 2, G. W. Boothby. **BARNDOWN OR CROSSBRED.**—*Chickens.*—1, T. Gunnell. 2, W. Collett. **SELLING CLASS.**—1, Mrs. Pest. 2, T. Gunnell. **DUCKS.**—*Aylesbury.*—Donation, Cup, and 1, T. Sear. 2, E. Macey. *Rouen.*—1, Elliston. 2, Mrs. Wood. *Any other variety.*—1, Leno. 2, A. & W. H. Silvester. **TURKEYS.**—Donation and Cup, Mrs. Mayhew. 2, T. Gunnell. **GESE.**—Donation and Cup, Deacon. 2, Kingsley.

**PIGEONS.**—**CARRIERS.**—Donation, Cup, 1, and 2, J. Baker. **POUTERS.**—1, J. Baker. 2, F. A. Thornton. **TUMBLERS.**—1, and 2, J. Baker. **FANTAILS.**—1, J. F. Loversidge. 2, J. Kendall. **ANTWERPS.**—1, H. Yardley. 2, J. Kendall. **ANY OTHER BREED.**—1, J. Baker. 2, E. A. Thornton.

**JUDGE.**—Mr. Tegetmeier.

## BLACKBURN SHOW OF POULTRY, &c.

This Show was held on the 27th ult., and was in all respects a success. Poultry were in the open field in excellent pens. The entries numbered near three hundred, and most of the eminent exhibitors were represented.

**Dorkings** not numerous, but very good. In *Brahma* cocks only the winners were noticeable; but these were in good order. *Brahma* hens were failing very much in feather, but otherwise good. *Spanish*, only one cock put in appearance, but in hens were five very good birds. *Game* cocks, first a good old Brown Red, and second and third chickens of the same colour. In *Game* hens were three grand Brown Reds, although the second was rather wild. *Cochins* good in both classes, the cocks especially so, and in very good feather; first and third Partridge, and second Buff. The first Gold-pencil cock was a gem, second and third also good birds. Hens were faded and not in high order. In Gold-spangled cocks were some almost perfect birds, but the hens were particularly good, the first and second in the best possible bloom. Silver-pencils only fine, but all noticed. Silver-spangles were not in as good order as other *Hamburgs* except the first-prize cock. Black *Hamburgs* good in all respects and in large numbers. The first in *Game Bantam* cocks was a well-known Black Red, second a Brown Red cockerel, and third a Black Red. Hens, first and third Black Reds, and second Pile. In the Variety of Bantam of both classes almost all were noticed, the winners mostly Blacks and Whites. *Houdans* were but poor in both classes, as is the case at most shows at present, but the other French fowls were better, and the prizes divided between *La Flèche* and *Crève*. Several classes were provided for local competition, and some of these brought out some good birds. The Variety class in *Ducks* proved a very first-rate one, and every pen was noticed.

*Pigeons* were also a good show, the classes being numerous, with three prizes in each, but only two Pouters turned up in the two classes. In Carriers the first-prize Dun was prominent, and was a grand hen. Almond Tumblers first a capital hen, second cock, third too dark. Foreign Owls a good class; pen 912 particular good Blue, best in class but not noticed. Barbs, first Red cock, good, but in poor order. Hens, first Dun, second Yellow, third Red, all good. Four classes for *Dragoons* brought a heavy entry, and in these were some capital birds of all styles and shapes. Antwerps a heavy entry, most of the best Lancashire and Yorkshire birds competing.

**POULTRY.**—**DORKINGS.**—Cock—1, J. Walker. 2, J. Stott. Hen—1, J. Stott. 2, J. Walker. 3, T. Kenyon. **BRAMA POOTRA.**—Cock—1, C. Holt. 2, J. F. Smith. 3, J. Haworth. Hen—1, G. Maples, jun. 2, C. Holt. 3, T. F. Ansell. **SPANISH.**—Cock—1, T. W. Finch. Hen—1, H. Beldon. 2, J. Smalley. 3, F. Cooper. *Any other variety.*—1, W. Finch. **GAME.**—Cock—1, C. W. Brierley. 2, W. H. Fenwick. 3, C. Smith. Hen—1 and 2, C. W. Brierley. 3, H. Thornton, jun. **COCHIN-CHINA.**—Cock—1, T. Aspin. 2, C. Holt. 3, T. Beardsworth. Hen—1, J. Walker. 2, T. Aspin. *Any other variety.*—1, H. Thornton, jun. **HAMBURGERS.**—Golden-pencilled—Cock—1, G. & J. Duckworth. 2, H. Beldon. 3, H. Pickles. Hen—1, J. Patrick. 2, H. Beldon. 3, W. Driver. **HAMBURGERS.**—Golden-spangled—Cock—1, H. Beldon. 2 and 3, G. & J. Duckworth. Hen—1, G. & J. Duckworth. 2, T. Dean. 3, W. Driver. **SILVER-PENCILLED.**—Cock—1, H. Beldon. 2, J. Ashworth. 3, H. Pickles. Hen—1, H. Beldon. 2, H. Pickles. **SILVER-SPANGLED.**—Cock—1, H. Beldon. 2, J. Ashworth. 3, H. Pickles. Hen—1, H. Beldon. 2, Ashton & Booth. 3, J. Smalley. **BLACK.**—Cock—1, H. Beldon. 2, B. Riley. 3, H. A. Clark. Hen—1, G. Moore. 2, J. Patrick. 3, J. T. Simpson. **BANTAMS.**—*Game.*—Cock—1, E. Walton. 2, W. F. Entwistle. 3, A. Smith. *Any other variety.*—1, W. F. Entwistle. 2, T. Barker. 3, W. Baskerville. **EXCEPT GAME.—Cock—1 and 2, E. Walton. 3, H. B. Smith. *Any other variety.*—1, E. Walton. 2, T. F. Phelps. 3, R. Hargreaves. *Any other variety.*—1, E. Walton. 2, C. M. Saunders. 3, H. A. Clark. **HOUDANS.**—Cock—1, S. W. Thomas. 2, J. Scott. 3, A. Ogden. Hen—1, G. W. Hibberd. 2, J. E. Clayton. 3, S. W. Thomas. **ANY OTHER VARIETY.**—Cock—1, E. Walton. 2, C. M. Saunders. *Any other variety.*—1, T. F. Rockham. Hen—1, E. Walton. 2, B. Myers. 3, C. M. Saunders. **SELLING CLASS.**—1, W. H. Benwick. 2, E. Walton. 3, J. Smalley. *Any other variety.*—1, J. Walker. 2, C. Holt. 3, Mellor Brook Poultry Farming Company. **RABBITS.**—1, J. Walker. 2, P. Unsworth. 3, C. Holt. *Any other variety.*—1, J. Walker. 2 and 3, J. Booth. *Any other variety.*—1, F. Johnston. 2, F. Houlker. 3, T. Knowles. **EXTRA STOCK.**—1 and 2, T. S. Ainsworth.**

**OPEN TO THE SOCIETY'S DISTRICT ONLY.**—**GAME.**—1 and 2, J. Woods. **COCHIN-CHINA.**—1, T. Beardsworth. 2, T. Pomfret. **HAMBURGERS.**—1 and 2, J. Patrick. 3, G. Barnes. *Any other variety.*—1, G. & J. Duckworth. **BANTAMS.**—1 and 3, T. Cropper. 2, H. Yardley. *Any other variety.*—1, G. Anderson. **ANY OTHER VARIETY.**—1, J. Smalley. 2, R. Worsley. 3, E. Spencer. **BRAMA POOTRA.**—1, G. & J. Duckworth. 2, H. Hargreaves.

**PIGEONS.**—**CARRIERS.**—Cock—1, J. Walker. 2 and 3, J. Chadwick. Hen—1, J. Gardner. 2, J. Walker. 3, T. Charnley. **YOUNG.**—1, J. Bamford. 2 and 3, J. Calcutt. **POUTERS.**—Cock—1, A. P. Byford. Hen—1, A. P. Byford. **TUMBLERS.**—1, H. Yardley. 2, T. Charnley. 3, J. H. Pyle. **BALDS OR BEARDS.**—1, W. Townsend. 2, T. Waterworth. **OWLS.**—*Foreign.*—1, J. Walker. 2, J. Wood. 3, H. Yardley. *Any other variety.*—1, J. R. J. Collier. **BARBS.**—Cock—1, J. Young. 1 and 2, J. R. J. Collier. 3, Major Crier. **DRAGOONS.**—*Blue or silver.*—1, Waddington & Booth. 2, R. Woods. 3, A. McKenzie. *Red or yellow.*—1, 2, and 3, R. Woods. *Any other colour.*—1 and 2, R. Woods. 3, A. McKenzie.

**YOUNG.**—1, J. Ercoyd. 2, R. Woods. 3, T. Charnley. **ANTWERPS.**—*Long-faced.*—1, W. Harrison. 2, W. Elles. 3, C. Hopwood. *Short-faced.*—1, W. Entwistle. 2, J. Ercoyd. 3, W. Harrison. *Any other variety.*—1, J. S. Collier. 2, W. Elles. 3, J. Wright. **TRUMPETERS.**—1, Mellor Brook Poultry Farming Company. 2, J. Wood. **TURBETS.**—1, G. Richardson. 2 and 3, T. W. Townsend. **JACOBS.**—1 and 2, W. Sefton. 3, G. Richardson. **FANTAILS.**—1 and 2, J. F. Loversidge. 3, J. Stanley. **OWLS.**—*English.*—1, W. Elles. 2, T. W. Townsend. 3, J. R. J. Collier. *Any other variety.*—1, J. R. J. Collier. 2, W. Elles. **NUSS.**—1 and 2, J. B. Bowdon. 3, Mellor Brook Poultry Farming Co. **MAGPIES.**—1 and 2, J. B. Bowdon. 3, J. Gardner. **LITTLEST BIRD FOR FLYING PURPOSES.**—1, Mellor Brook Poultry Farming Company. 2, W. Shaw. W. Wilkinson. **ANY OTHER VARIETY.**—1, J. Gardner. 2, G. Richardson. 3, H. Yardley. **SELLING CLASS.**—1, C. E. Chavasse. 2, T. Charnley. 3, A. P. Byford. **RABBITS.**—*Spanish.*—1 and 2, Schofield & Barrett. 3, T. & E. J. Fell. *Any other variety.*—1, J. Jones. 2, R. H. Swain. **HIMALAYAN.**—1, T. & E. J. Fell. 2, S. H. Leach. **SILVER-GRAY.**—1, H. Woods. 2, J. Firth. **WOODS.**—1 and 2, J. R. Noble. **ANY OTHER VARIETY.**—*Buck or Doe.*—1, E. Pilgrim. 2, W. C. Slater. **SELLING CLASS.**—1, Schofield & Barrett. 2, T. M. Atkinson.

**JUDGES.**—*Poultry.*—Mr. E. Hutton. *Pigeons.*—Mr. J. Esquilant. *Rabbits.*—Mr. J. Boyle.

## BIRDS FOR EXHIBITION.

IN answer to "AMATEUR," we reply that one-half the battle is to send birds to the post in a cleanly condition, and not only the birds should be clean but the cages also. Not knowing what birds you wish to exhibit we cannot advise you as to what kind of cage to use. You will perceive by the announcements of exhibitions in the Journal from time to time when they will take place. This will afford you ample scope for the exercise of your fancy. In the advertisements you will notice the closing of the entry days, before which time you must apply to the various secretaries for schedules and certificates of entry. In filling up the certificates make them out yourself according to the printed instructions. Write your name and address distinctly, and state the age, sex, and breed of the bird you may wish to show, and fix a price for the sale of it in case of its being claimed. When sending off your entry forward by post-office order the amount of money entitling you to show, and likewise securing for you a catalogue and list of awards. Be sure and fill up and return the certificate before the expiration of the time specified for the closing of entries. Send off the bird for show so that it may be received in time to be judged, or it will not be noticed or entertained by the judges if it arrives too late for competition. Use a substantial wrapper for your cage, upon which wrapper let your name be attached, or probably it may get mislaid or fall into someone else's hands. When you receive the labels from the secretary (if you are exhibiting above one specimen) see that they are correctly tied on the cages, or your birds will be wrongly classed at the exhibition and will be disqualified, and all your trouble and expense will be in vain. Use tin vessels, and send enough food for the bird or birds during absence from home. Convey your birds carefully to the railway station, and if possible let them travel by night train, for the loss of a little rest will not be so bad as the loss of food during the day-time. Wooden cages with wired fronts can be easier packed than wire cages. It is best when transmitting the latter to a show to have them surrounded by or inserted in a skeleton wooden frame, so that the wires may be protected. But do the best you may, your cages will be subject to rough treatment at times by some railway porters, who pitch and throw hampers and cages about as though they were pillows, regardless of the frail and expensive occupants. And sometimes much delay will be caused in the return of the birds, and each cage being packed separately, thereby laying you in for extra parcels rates, all through the want of a little attention and the use of some extra cord to attach the cages in one parcel.—G. J. BARNESBY.

## HEATHER FOR BEES.

THIS usually begins to open its flowers at the commencement of August, and, weather permitting, will yield honey for a month. If the weather be unexceptionably favourable strong swarms in large hives will gather from 30 lbs. to 60 lbs. in fifteen days. The heather is, I think, rather later this year, and will not be in very good condition till about the 12th. Let me remind beginners of the danger of breakdowns in removing bees in hot weather. Young combs in hot weather are about as soft as new-made butter, and very easily shaken from their holdings. The best time to go to the moors with bees is after they have been kept indoors by weather for a couple of days. If the hives be well ventilated and the combs be fastened to cross-sticks there will be little danger of the combs falling. Every precaution should be adopted. Hives without cross-sticks should have their combs steadied and supported in some way two days before they be removed. Common corks and half corks stuck between the combs, or two sticks laid across the board to touch the bottom of the combs, will assist them very much. Without a run on the heather, swarms will be comparatively light this year in our neighbourhood.—A. PETTIGREW.

## A MODEL POULTRY HOUSE.

THE fowl house illustrated herewith was designed by Mr. J. A. Storm, a prominent breeder of St. Joseph, Mobile, and is now

used by him with satisfaction. It consists of four rooms with runs attached, arranged around one centre room, so that with good light and ventilation the four apartments may be under the control of the attendant, and the fowls fed, watered, and

Fig. 11.—POULTRY HOUSE.

eggs gathered from the centre room without disturbing the fowls. The entire house may be heated from the centre room, which has a trap door to prevent the escape of heat. The par-

titions are of latticework, allowing free ventilation and an unobstructed view of the fowls. The rooms and yards are each supplied with running water

Fig. 12.—SECTION.

from the tank (J), which has four pipes leading to water-pans; twenty in number, and 16 by 20 inches in size. They are so the supply is regulated by means of cocks. The nests (H) are arranged that hens may enter them from the runs or from the

centre room as may be preferred. The tops of the nests are hinged for convenience in collecting eggs and attending to sitting hens.

When the hen wishes to sit, the opening from the run to the nest is closed, and the opening leading from the nest to the centre room is opened, so as to allow the hen to feed and water at pleasure, as in the centre room there is fresh water and food, &c., kept at all times. The object of such an arrangement is to prevent other fowls from laying to your sitting hens.

The roosts (r) are made of 1-by-6-inch pine, placed 2 and 3 feet from the floor, and so arranged that the droppings from the higher roosts cannot fall upon the fowls on the lower, and so far from the wall as to protect the plumage. The size of the building is 20 by 20 feet; the centre room is 8 by 8 feet; the outer rooms 6 by 8 feet; the height of the storey is 8 feet; the windows (w) are 2 by 4 feet, and the doors (d) 2 by 7 feet. The building is made of 1-inch pine boards, sheathed up and down with battened cracks, and lined on the inside with heavy tarred paper to prevent all draughts and cold in winter, and prevent vermin from collecting in summer. The entire building has a rough floor covered with sand, and is kept raked clean. The runs (A) to each room are 40 by 40 feet, and adjoining a grass run 80 by 100 feet for hens and chicks. The small house (L) for hens and chicks has a floor placed 2 inches from the ground, with an open run attached to allow the sun, and to prevent the larger chickens from disturbing them while feeding.

Instead of the door being in the outer end, it is in the end leading to the covered run, and hinged at the bottom so as to lay down on the ground for small chicks to enter, and at night it can be shut to protect from rats or vermin. One side of the roof is hinged so as to open to attend to the hen and chicks. After using this house for three years Mr. Storm considers it the best and most convenient known. The house will accommodate fifty hens, and can be diminished or enlarged at pleasure by changing the number of wings, and still retain all the conveniences.—(*Prairie Farmer*.)

### THE CUCKOO.

LONGLEAT, with its beautifully wooded park, is a favourite resort for the feathered tribes—in fact, some of the kinds are much too numerous, notably Bullfinches and Wood Pigeons; but Swallows, Wagtails, Cuckoos, Hedge Sparrows, and other insect-feeders are ever welcome, for the good they do is incalculable. We generally have several young Cuckoos reared in the neighbourhood. All that I have seen are reared by Wagtails, though occasionally I believe they are found in the nest of the Hedge Sparrow.

Last year, as late as the beginning of August, three of them were in the flower garden close to Longleat House, all tended by Wagtails; and their industrious foster parents had to work exceedingly hard to appease the appetite of their gigantic babies, who were quite strong on the wing, and looked large enough to swallow half a dozen Wagtails at a meal. I noticed at last that the Swallows became exceedingly jealous of them, fearing no doubt that they would cause a famine, and they bullied them a good deal, and I believe ultimately drove them away.

This year we had two Wagtails' nests in Pear trees against walls, each of which contained a Cuckoo's egg. One lot was destroyed, probably by rats; the other was hatched-out, and the Cuckoo kept on the nest long after he was too large to squeeze himself into it, and is now about the neighbouring trees carefully tended by his foster parents, who are evidently very proud of their infant prodigy. Of course the life of the young Wagtails which happen to be in the same nest with the Cuckoo is very short, for from the moment the intruder emerges from his tiny shell his mouth is open for all the insects the old birds can bring, so that if the young Wagtails are suffered for a time to remain in the nest they are certain to be starved. The Cuckoo's egg is very small for so large a bird, being but slightly larger than that of the Wagtail; but as soon as hatched the young bird grows at an immense rate.—WM. TAYLOR.

### ABOUT BEES.

THE extraordinarily hot weather which set in with July, and which had been growing in intensity up to Sunday the 16th ult., where it has not dried-up the flowers, has been magnificent for our bees. Happy those bee-keepers who, hoping against hope, fed and nursed their hives through the very trying winter and spring of 1875-6. Poor as my bees were in April and May, they have picked-up wonderfully, and I had the pleasure (before leaving home on the 10th), of taking off a large super weighing 33 lbs. net of excellent honeycomb from the hybrid Italian stock, which also had given me a swarm. A curious thing occurred in relation to this stock which I never recollect to have observed before in my long experience as a bee-keeper. Although this hive sent out a swarm early in June, of which fully half returned to the parent stock owing to my having put the swarm within a foot of it, and consequently the stock seemed

as full as ever, there was no piping heard at or after the usual time, nor, of course, was there any more swarming. On cutting-out the honeycomb from the super I found several of the combs had had brood, which was almost all hatched, and there were about half a dozen royal cells torn open at the sides as by a young queen. Had a second swarm issued, which I fully expected, it must have been a very large one. The surprising thing is that there was no piping.

As to the super of honeycomb, I had hoped to exhibit it at our coming Weston-super-Mare Show, but I was obliged to take it before it was fully filled owing to my projected absence from home, and the necessity of giving the bees ample additional room. Owing to the lateness of the season all my calculations and plans have been thrown out, and nothing remained but to give all hives and swarms as much room as possible to avoid late and lost swarms. Of late years my bees have chiefly swarmed in July, and many of them have been lost to me. Here in North Wales, I find bees swarming too, but this, perhaps, is the proper time amid the heather.—B. & W.

### MARKETABLE HONEY.

GREAT attention in America is being paid to sectional supers, which are very neatly and cheaply made. The wood is cut by circular saws, and with guide combs attached are sold for less than 1d. each. This is cheap enough to be given away with the honey, although being very light they are usually weighed and charged to the customer like the sugar-paper of the grocer. When the British bee-keeper learns wisdom enough to send his honeycomb to market in fine saleable form there will be no need to cry, "There is no market for honey." In case I am asked what I call fine saleable form I answer, Each comb should be distinct and full, in a frame or at least attached to a bar, cells all sealed over, unbruised and uncontaminated by brood or bee-bread; weight not over 4 lbs.; colour white or clear yellow. Such honeycomb in London is sold retail at from 2s. to 3s. per lb. according to the class of customer, and wholesale from 1s. 3d. to 1s. 6d. per lb. I had the pleasure of taking off this week two of Lee's supers filled with the above description of comb which a west-end grocer bought without demur at 1s. 6d. per lb., at the same time telling me he could buy any quantity of full combs out of hives at 10d. per lb., but the mess and waste was so great he would rather be without it.

Mr. Pettigrew's idea of filling small frames with such combs and then giving them to the bees to clean and fix will be found a failure. The bees' first and only idea would be to fill their hive, and to do this they will very quickly empty the strange combs. I have tried it and know it fails, although I gave them a much better chance than Mr. Pettigrew promises with his unfurnished hive. I will cite two instances. Last autumn I fed-up a stock with sugar syrup, and then when their combs were apparently as full as they would hold of brood and honey I placed over them a super of damaged combs, which I propped up and temporarily fixed where I wanted them to remain. The super was at once taken possession of, but very little repairs went on; the wet honey was quickly gathered up and carried below, and I soon found that as fast as ever bees hatched out or honey was consumed down went my super honey to fill up the vacancy, so that my combs were lighter day by day.

Last week the honey harvest suddenly ceased with me, and in a super over a strong stock I had two outside combs with their corners not full. Careful watching convinced me that some fresh cells were emptied every day, so I slung out some honey from a neighbouring hive and gave 3 lbs. of it in a feeding bottle for the bees to finish their super with. Now the bees carried this all down through the super to the stock hive. Not one ounce did they leave on the way; and when the bottle was quite empty, like little lunatics they tore open the cells and half emptied two combs in twelve hours. This was too much of a joke, so the remainder was at once taken away, and the spoil of the thieves is awaiting a few turns of the extractor and my leisure to increase my store within-doors. I thought I would try what another stock would do; and selecting one where the bees were crowding into a super but doing no work, I placed on the frames without the interposition of any crown board a set of sectional supers, and over them two bottles of new honey. As in the other hive the bees carried this all below, travelling over a nice new empty decoy comb, which they left as empty as they found it. I cannot help chuckling at the future disappointment of the little rogues, for the honey is only lent; ten minutes' work of the extractor will bring it all back.—JOHN HUNTER, *Eaton Rise, Ealing*.

### MODIFICATIONS OF MANAGEMENT.

CIRCUMSTANCES alter cases. Necessity has no laws. The farmer considers the condition of his land and the markets around ere he adopts a three or four-course rotation of crops. The gardener has soil, climate, and the wants of the family of his employer to consider. In bee-farming no hard-and-fast line

should be drawn. Every active open-eyed apiarian seeking profit goes beyond the A B C of his lessons and improves on his own practice. As the houseleek feeds on its own substance, so farmers, gardeners, bee-keepers, &c., grow stronger by feeding on their own experience. There is no end to the variety and modifications of management in the apiary. Within its limits there is scope for unlimited operations and developments of practice. A few hints may, perhaps, be gathered if we now give a little of our treatment this season.

We have turned out the bees from all our stocks and taken their honey, which is excellent, and is being readily sold at 1s. 3d. per lb., comb at 1s. 6d. This first harvest has been moderately bulky—larger than any other early harvest we have had for some years. The greatest yield has been from a hive containing 3600 cubic inches of space—namely, 18 lbs. of pure virgin honeycomb and 17 lbs. of run honey, value £2 8s. The two swarms from this hive are now filling hives containing 4200 cubic inches of space each. The cold weather of the spring months was very unfavourable for both breeding and brood, causing us to fear the beginnings of foul brood. In all the hives taken we found foul brood to a small extent, which would certainly have spread rapidly and spoiled the hives for both keeping and working if the bees had been allowed to remain in them. Now, with two exceptions, our hives have sweet combs not two months old and free from a cell of foul brood. Two large hives with honey in them died in the spring. From these we cut out all the centre combs and put swarms in them. The outside combs containing the honey of these two hives are the only combs that were built last year. The turning-out process is very useful to us, for by it we rid our hives of combs stained by use and cloyed with pollen. The hives yielded about 25s. worth of honey on the average. The combs in most of them, though only twelve months old, were rendered nearly useless by a superabundance of bee bread. In some of the hives five cells out of every six in the breeding-combs contained pollen, and made the combs about as solid as cakes of gingerbread. I cannot understand why anyone can recommend the use of pea flour for bees. Why the bees accumulate such quantities of pollen, and thus prevent healthy progress, is equally difficult to understand. To witness the dissection of a hive as we dissect ours would be enough to convince our readers of the superfluity of pollen existing in hives.

The best time for turning bees from stock hives is about the twenty-first day after first swarming, for then the brood is all hatched and the swarms have time to fill their hives with combs and store up food enough for winter or for a second harvest. When hives are in an unhealthy condition and not thriving we turn their bees into empty hives, where they generally commence house-furnishing with new zest and vigour. The progress of one of our hives this season was so sluggish that I came to the conclusion that the bees were discouraged by the presence of foul brood. On examination I found it was so, and at once turned the bees into an empty hive, in which they are now doing well.

Some late swarmers had queens from early swarmers, and these queens began to lay before the brood in them was all hatched. At the end of fourteen days we drove the bees into empty hives, and thus sacrificed the unhatched brood for the benefit of the swarms. By adopting the turning-out system of management a bee-farmer has flower or clover honey in the market very early, and this to us is a great advantage, for our home customers are exceedingly fond of flower or clover honey; we therefore try to get as much of it as possible before the bees are removed to the heather. In honey seasons our swarms become heavy before they are removed to the moors. Sometimes we use the comb knife and greatly lighten them before removal.

In unfavourable seasons for honey-gathering it is sometimes a stroke of good policy to increase the number of stocks, and in very favourable seasons to reduce their number by taking all the honey possible. Within the last ten years we have had two seasons remarkable for honeydew, which spoiled and discoloured the honey, making it quite unsaleable. What is called honeydew is simply the dirt of an insect, which when gathered by bees is an abomination in hives. It is not healthy food for bees, but they eat it. We take no honey for sale or from bees when they gather honeydew, but increase our stock of hives. On the other hand, when all our hives rise to great weights the temptation to make hay while the sun shines (to use a common expression) is very great. In such seasons it is a stroke of good policy to run a great deal of honey into the money bag.—A. PETTIGREW.

## OUR LETTER BOX.

**POULTRY-KEEPING EXTENSIVELY (H. B. B.).**—We do not believe you will get a living by selling eggs or by keeping poultry in confinement. If you have a farm of thirty acres, affording your fowls a good range, and enabling you to grow the food, and thus get it at the lowest cost, you will find poultry a great help; but like everything else that is intended to pay and contribute to a living, or it may be something more, they must be well attended to,

and not cared for in spare minutes or fed with refuse. Near a town there is always a good demand for eggs; and wherever good poultry is offered for sale there is always a demand for it. The calculation of the number of eggs that will produce enough to keep a man would not be difficult if we knew the sum required.

**CHICKENS FEATHERING BADLY (Amateur).**—We disapprove your feeding altogether. We are almost tired of telling people they will only do well with poultry while they follow nature. We believe in no artificial foods, and where poultry is most successfully kept you will never find any of them. The only good thing you have is lettuce; give them plenty of it. Give ground oats or barley meal slaked with milk. Give them fresh earth moved with a fork. The food you have been giving is heating, and the feathers are dried up before they are entirely formed. Do as we have told you and your birds will soon be feathered.

**CHICKENS DYING (Leyland).**—We do not consider your feeding good enough for chickens, and but for the help they have running about the garden more would have died. Indian meal is bad, possessing nothing but fatty matter, at a time when bone and muscle are wanted. Sharps are bad. Chickens want the best of everything, and if they are stinted when young they never make up the lost way. At five weeks old they should have bread crumbs, ground oats, crushed wheat, chopped egg, cooked meat scraps chopped fine, table sweepings, and oatmeal mixed with milk. These can be diminished as the chickens grow older. All the modern appliances in lieu of good wholesome food tend to loss of power. Fat is not strength, nor does bulk in chickens prove they are doing well, unless it is sure that it is the result of nourishing and plain food, such as birds get in a state of nature. It is feeding such as yours that brings leg-weakness and other maladies.

**CROSS-BREEDING FOWLS (Mrs. P.).**—Houdans and Dorkings can be interbred.

**SEEDS FOR BULLFINCHES (T. R. W.).**—Full directions for feeding them are in our last number. Any grass seeds will do.

**WHITE DRONES (Leyland).**—The sentence which you have quoted from the "Handy Book of Bees" is not absolutely correct, and should have been explained, for it was meant to cover the conduct of the bees before swarming and undisturbed by enlargement. Drone calls are filled with brood in the expectation of swarming, and often when weather brights the hopes of the bees and threatens them with poverty they begin to cast out white drones. In times of prosperity before swarming, or when all is in an advancing condition towards swarming, healthy white drones are not dragged from their cells. Your hive has been doing well, but since you have enlarged it by eking and supering the weather has become much colder, causing the bees to abandon the idea of swarming; hence they have commenced casting out their worthless young—a wise provision in the economy of a bee hive. Towards the end of the summer white drones are frequently cast out of heavy full hives, and even during the summer months one may see the bees dragging out young drones that died in their cells before the time of hatching.—A. P.

**CANARY WITH HEAD ALMOST FEATHERLESS (Theda).**—Red sand is the best, but still the want of it would not cause the bird's head to be bare of feathers. If, where the feathers are off, there should appear any scurf, gently rub or anoint the part affected with oil of sweet almonds, or lard, or fresh butter. Give the patient a drop of castor oil twice each week during illness. Discontinue the use of apple, and so much green food. A little lettuce or watercress every other day will suffice. Let canary seed form its main food, giving still less hemp and rape, and by all means scald the latter before using it. If you could devote a spare room or spacious fly to the bird during the moulting season, supplying a bath daily, perchance your pet would recover its plumage.

## REMARKS.

26th.—A bright fine day, with a cool breeze, especially at morning and evening.  
27th.—Rain for short time in early morning, very fine at 9 A.M.; a beautiful day with pleasant breeze.  
28th.—Rather dull morning; rain began at 1 P.M., and there were frequent showers during the rest of the day.  
29th.—Very bright and pleasant day after the rain of the preceding one.  
30th.—A very bright pleasant day and night.  
31st.—Rainy morning, fine forenoon, but heavy showers in the afternoon; peculiarly storm-like sky at sunset, though it was a very bright one.  
1st.—A very fine day but rather cool.

Like the preceding week, that just closed has gradually decreased in temperature, the maximum in shade which was 92.6° on July 15th was only 69.7° on the 1st of August. The total fall of rain in July was only 0.815 inches, being less than half the average.—G. J. SIMONS.

## COVENT GARDEN MARKET.—AUGUST 2.

A BRISK business has been doing during the past week, and nearly all classes of goods have been easily cleared owing to the falling-off in the supply of soft fruit.

From observations taken near London during forty-three years, the average day temperature of the week is 74.2°; and its night temperature 50.6°.

## WATERING FRUIT TREES.

**U**NQUESTIONABLY a matter of considerable importance is the supply of water to our hardy fruits. It is especially important during seasons when the trees are laden with heavy crops of fruit. It is clear that these fruits cannot be perfected without an adequate supply of water. After an exceedingly productive fruit year how often is the next year barren. The trees cannot perfect their exhausting crops and at the same time

lay up a sufficient store of material for the crop next following.

It is sometimes forgotten that fruit trees have this double function to perform—they must not only carry the crop to perfection, but they must also provide the blossom for the following season. Now a fruit tree will not divide its force equally between these two requirements. With the tree the primary object is to perfect fruit and ripen seed, the production of blossom for the year following being secondary. Its whole resources are appropriated first to satisfy the cravings of the fruit, and only when it has surplus power is this devoted to the extension of the tree and the preparation of future crops. This is seen by an overlaid tree refusing to make growth. How many trees—how many orchards are there—which have a sort of historical notoriety for bearing “every other year?” They are found in almost every parish where fruit is extensively grown—it is hardly fair to say cultivated. Such trees have only power to perfect their fruit, and have no surplusage to provide for the next season’s crop. As masters we must guide and assist the trees, and they will be good servants. We must not work the trees unreasonably, neither must we nurse and pamper, or the position becomes reversed, and the servant is in the position of master, and does what he will and not what we wish.

Now when once a tree is fruitful it is guided to further fruitfulness by the way it is treated. It is not too much to say that thousands of trees are every year over-weighted, and the fruit must be thinned or the roots must be watered. If either or both these aids are not afforded the fruit of the year will not only be excessive, but the trees for next, and it may be future years, will be rendered unprofitable. “But we cannot thin the fruit or water the trees of an orchard,” some may say. Certainly not; but apart from that, a quick decision and setting to work instead of arguing the point of how little can be done will result in immense benefit to many trees within the reach of our means, and which by lethargy, fancied inability to aid, or erroneous reasoning may be left to become debilitated, and neither contribute profit nor credit to the grower.

But besides lethargy there are erroneous notions to combat. It may be held that fruit trees do not require water, simply because excess of moisture by undrained ground is injurious. There are those who have such a horror of water that nothing could induce them to water

a Vine border or a fruit tree. They point to the evils arising from roots reaching the subsoil, and hence refuse to apply water. It is true a wet hungry subsoil is pernicious to fruit trees; but how come the roots there? Trees must have water, and if it is not afforded them near the surface they will ramble in search of it and food into the most sour, ungenerous, and waterlogged soil. They do not rush down there in the winter, but it is in the summer when the sun is exhausting them of life that they strike down for the support which they cannot find near the surface. Unfortunately they cannot in the autumn withdraw their roots, or the evil would be much lessened. Giving trees, including Vines, good support near the surface in the summer is the best preventive of their being in a deleterious medium in the winter. The best Grapes and the finest fruits of all kinds are produced by copious supplies of water. It is surprising how much water a fruit tree in full bearing will appropriate, and never without benefit to its exhaustive crop of fruit.

But all trees do not require to be watered, yet it is easy to determine those which would be benefited by a thorough feeding at the roots. If a tree old or young is making a free growth of wood no stimulant is needed; but if, as is the case with so many trees at the present time, the fruit is appropriating all the support which the roots can supply, and there is no surplus strength to provide healthy spurs and satisfactory extension growth, then the fruit must be further thinned, or support must be given to the roots. Wall trees which are heavily laden and growing in light soil on hot aspects will be much benefited by the application of liquid manure, and over this a surface dressing to arrest evaporation. A day’s work now and then devoted to this matter would be more profitable than is generally understood. Vine borders, the surface of which is impoverished and dry, should be enriched by the same means, for the roots will not be so active to dive down in search of food and moisture if a due supply is afforded them nearer the surface. Pyramid and bush fruit trees crushed to inactivity by a heavy load of fruit will derive great assistance by a thorough application of liquid food. Even a prized old Apple tree, it may be a Ribston Pippin, or any sort the fruit of which has a special value, will have vigour imparted to its weakened frame by a cartload of liquid manure given to the roots. A Pear tree which is carrying pecks of fruit, it may be a Citron des Carmes or other approved sort, from which it is desirable to have all the fruit possible and of good quality, will rejoice in the gift of a liberal supply of liquid manure. It will make all the difference between cracked and deformed fruit and full-sized smooth specimens—between refreshing juiciness and full flavour, and dry mealiness and insipid flesh.

Experience in a dry district enables me to speak with confidence of the great benefit which heavily-laden trees, young and old, on walls or in the open garden, derive from one or two thorough soakings of liquid manure during the swelling season. A liquid-manure tank which takes the drainings from dunghills is a store of great value and a rich larder of food for exhausted fruit trees.

Where such a store is not provided guano affords the most ready means of manufacturing liquid food. It may be applied at considerable strength to aged fruit trees. I have used it at the rate of 3 or 4 ozs. per gallon with the very best results.

But it is only in the case of trees that cannot make wood growth to which applications are needed. If there are 6 inches of healthy extension growth manurial assistance is not necessary; but if there is no such extension growth, or if the foliage is yellow, the wood small, and the fruit not swelling so freely as is desirable, then a copious application cannot fail to be of great benefit to such overworked trees (and they are numerous), not only in improving the present crop of fruit, but in preparing the trees for better service in future years. —A NORTHERN GARDENER.

## LESSONS OF THE SEASON.—No. 1.

### SPRING.

A DREARY spring, cold and wet, with fitful and rare gleams of sunshine, the soil sodden and cold, young and tender vegetation stunted, crippled, and blighted, foliage torn by the wind and hailstorms, blossom most abundant, expanding but to die. Such was the spring of 1876—a season of ungenial severity, a time of trial such as is not often experienced even in our fickle changeable climate. It was emphatically a season of results arising from unmistakable causes—results that were for the most part disastrous, but which are not without their value from the plain teaching which they gave us of lessons hard to learn.

To begin at the beginning, let us first turn to the soil and afterwards to the crops growing therein; for without good soil it is quite useless to plant or sow, however favourable the season may be. The fact is so self-evident that to put it on paper appears almost an absurdity, and yet do we not constantly hear it said that soil is so heavy, stiff, sodden, cold, that timely planting is impossible? Remember, it is not of a field or farm land I am writing, but of those choice morsels of mother earth termed gardens, sometimes defined as “rich well-cultivated spots,” so precious as to be enclosed by costly walls and fences. Now one would naturally suppose that when a portion of land is so enclosed it would forthwith be wrought into the highest possible state of cultivation; but this is very frequently only half done, the unfinished part, the weak point, remains unaltered till it leads to almost total failure. In a cold wet spring like that which we have just experienced soils badly drained or deficient in gritty matter were so saturated that cropping was out of the question; there was nothing for it but to wait for brighter times—a serious matter when a steady unbroken supply of vegetables has to be maintained.

I have soil in various stages of improvement, from a barren crude state up to a light, rich gritty—very gritty—condition, the best of which I consider to be as nearly perfect as is necessary for all practical purposes. It is thoroughly drained, is rich in fertilising substances, and contains so large a proportion of gritty matter—really coal ashes and shattered bricks, that a tool will pass readily through it however wet it may be; so that seeds may be, and in point of fact are, sown on the first fine day in a season of undue wetness. In proof of this I will give one or two dates. On February 24th the rain held up; the sun shone with a drying wind; Canterbury hoes were run through the soil in the morning, and in the afternoon drills were made and seed sown of Brussels Sprouts, Cauliflower, Early Broccolis, Cabbage, Savoy, Leek, Turnip, Carrot, Radish, Lettuce, Spinach, Parsley, and Peas. In due course the crops came up strongly and well without a single failure, all of them proving of the very greatest service. Now this soil, in addition to its high state of culture, had the advantage of being thrown up roughly in autumn, and thus lay ready to my hands when the opportune fine day for which I was on the outlook did occur. To show how important it was to seize that fine day I refer to my journal and find the following entries. February 20th, a wet Sunday; 21st, wet and stormy; 23rd, a rough dull day; 26th, a dull showery day; 27th, another wet Sunday; 28th, a showery morning; 29th, showery all day; March 1st, a wet morning; 2nd, a fine morning, which soon changed to a showery day; 3rd, another day of miserable weather, a high wind with rain all day.

Let not anyone suppose that I possess exceptional advantages, or that what I have done may not be accomplished even in the smallest gardens. The mistake which so many of us make is in trying to do too much in the first instance. To improve the condition of the soil of a single border is a very

different matter to applying a similar process to an entire garden, and yet by having that one border in suitable condition for a seed bed at any time we secure a supply of seedlings ready for transplantation to less favoured spots later on, and yet quite early enough to secure good and seasonable crops. By all means let us cultivate every part of the garden as well as we can, but in doing so let us make sure of having a certain portion in a condition of high excellence, aiming to bring the remainder up to our standard however slowly it may have to be done.

Summer is passing rapidly away. Let me urge upon those who have a bad soil and are aware of its attendant evils, to rival my seed borders by devoting special attention to one or two of theirs in the ensuing autumn. Do not rest content with just putting on manure and throwing up the soil roughly to frost and wind; but first of all dig it over, then put on a layer of old manure and hard grit—road scrapings, coal ashes, stones broken finely, mortar rubbish, burnt clay, or shattered bricks. Any of these will answer admirably provided you use enough, say 6 or 9 inches, of manure and grit. Stir this well into the soil, turning it over till a thorough mixture is effected, then lay it up in slight ridges or in any rough fashion for the winter, and whether next spring prove wet or fine you will have an excellent seed bed, not only because its free open nature will enable you to sow at almost any time, but also because it is that very property, combined with its richness, which will ensure prompt vegetation and a free strong growth.

The foregoing formula applies generally to new rather than to old gardens, yet strictly speaking it is applicable to all soils that are of a poor, close, or heavy texture. In old gardens the soil is very frequently found to contain such a superabundance of humus as to induce a soapy condition in a wet season. The very best corrective for this is a free dressing of lime and coal ashes, after making sure that the drainage is all right. Many a garden suffers in spring from defective drainage, which, in addition to the sodden condition of the soil, or rather for that very reason, induces a low temperature and a moisture-laden atmosphere that is very hurtful—often fatal to tender vegetation.—EDWARD LUCKHURST.

## DOUBLE PYRETHRUMS FROM SEED.

THE value of these as decorative plants in early summer is being recognised, and the beauty of their blooms—varied hues and brightness being combined with form and endurance—enable them to rank high as cut flowers. The “cup” of the Rose and “incurve” of the Chrysanthemum may be wanting; nevertheless, what the Chrysanthemum is in autumn these are in early summer—half balls of loveliness, equalling in size Anemone-flowered Chrysanthemums. The plants commence flowering in May, and are at their best in June, and are by their distinctness of form and diversity of colour likely to meet with a more than ordinary share of patronage. This year, from the end of May to the second week in July, blooms were available for cutting, and a further supply was afforded in late summer and autumn.

The Pyrethrum has been much improved of late years. There are many very fine named varieties, but it is not of those that I wish to descant, for there is a vast majority who would not invest in a dozen plants in variety who need no prompting to speculate in a packet of seed. In the matter of Pyrethrums I have had from packets of seed no more single flowers than are to be found in Ten-week Stocks.

Seed sown early in August in light sandy soil in a warm situation and lightly covered with fine soil kept moist will germinate in a few days, and the seedlings may remain in the bed until spring; but I think it best to prick them out when they are showing the second leaves into rows 6 inches apart and 3 inches apart in the rows, in light moderately rich soil in a sheltered situation, shading for a few days if the weather be bright until established, moving in March or early in April to their flowering positions. A moderately light well-drained soil is desirable, enriched with leaf soil or well-decayed manure. Two feet from plant to plant is a proper distance for them in the mixed border, but I prefer to plant in “trial” beds, putting out the plants in 4-foot beds, four rows in a bed, with a foot distance between plant and plant. When advancing for flowering they are grateful for liberal support in dry weather. Weak liquid manure once or twice a week or oftener, according to the weather, is beneficial. Many plants are pronounced poor because there is nothing in the soil to bring them out differently.

Indifferent and superior cultivation makes the difference between poor and good blooms.

If a plant shows a single flower—a single row of petals with no centre florets—pull the plant up, and mark such flowers as are desirable by their size, doubleness, and colour for continuance. Not unfrequently there will from a packet of seed be a fair proportion of plants in the various shades of colours—white, pink, and rosy shades up to carmine and crimson, with sparse sulphur tints. Save the best of each colour—i.e., if it be wished to go on improving by raising plants from seed, and any not wanted for that purpose may be planted in the mixed border. After flowering the flower stems should be cut away, and in their place will arise others, giving flowers in late summer and autumn. Beyond a liberal dressing of manure, leaf soil, or other compost in autumn as a top-dressing to be pointed-in in early spring, they do not require any further care, and they will last for many years.

Seed sown in spring—in March, in pans, and placed in a hot-bed, keeping near the glass and well ventilated—will produce plants which if well cultivated will flower towards the end of summer, and give a grand bloom in the June succeeding. Seed may also be sown in May in the open ground, the plants being pricked-off when large enough, and finally planted in the blooming beds with the first moist weather in September, and they will flower well the following season.—G. ABBEY.

### THE POTATO DISEASE.

I HAVE read attentively and with great satisfaction and instruction the lucid article of Mr. W. G. Smith, and I consider that article and the admirable illustration accompanying it on pp. 52, 53, and 54, the most clear and intelligible of all the scientific contributions which have ever been published on this subject.

We see now the seeds of the disease clearly and plainly. The working of the disease is now placed beyond the bounds of conjecture. Mr. Smith has, I believe, received the recognition which he has so well merited by his patient and careful research and successful discovery at the hands of the Royal Horticultural Society, and I for one practical gardener congratulate him most cordially.

There is only one sentence in Mr. Smith's letter over which I stumble. It is this—"As the healthy Potato will always take the murrain from these spores as certainly as a healthy man will take the small pox when inoculated for that disease, it is reasonably considered that the Potato fungus will cause the disease." It is the word "always" to which I take exception; for in the year 1872, when the murrain was unusually prevalent, I made several experiments by way of communicating the disease to different varieties of Potatoes, also to the same varieties under different treatment, and the result of my rude experiments was that Potatoes will not "always take the disease." Some varieties took it quicker than others, and some under glass not at all, while others under glass became affected when the artificial treatment to which they were subjected rendered them amenable to its attacks; in other words, when the sap of the plants and the surrounding atmosphere were in a proper state for the germination and spread of the fungus.

I was led to think then, and I think still, that the sap of the plants must be changed and be in some way impure before the fungus-spores find a suitable medium for their development. I think, therefore, that the primary cause of the Potato disease is impure sap. Mr. Smith, like a loyal fungologist, believes that fungus is the cause of Peach blister, but others, and myself amongst the number, think it is only the consequence of an anterior cause. In assuming that the fungus is the cause of the Potato disease Mr. Smith reasons by induction. Nearly any preconceived opinion may be supported by induction. By induction also we may arrive at an exactly opposite conclusion. It is not very unreasonable to consider that the Potato fungus is different in its nature to other fungi. Most if not all of these are by many regarded as Nature's scavengers—feeding on the impure. Mould on jam may be seen, but the jam first "goes bad." We may not perceive the impurity until we see the effects of it in the germination of the fungus spores, and then, perhaps hastily, we confound the cause with the effect.

I have taken Potato haulm reeking with the disease and attached it to healthy plants, and in some instances the disease has "took" at once, while with other varieties or conditions of the same variety it has either "taken" very slowly or not at all. If a Potato plant is perfectly healthy and vigorous it

will not take the disease, unless the atmosphere is unusually moist and the temperature abnormally high. I have proved this on a small scale artificially, and many years and sad loss of crops have proved it on a large scale naturally, but to say that the Potato will "always" take the disease is not a fact.

There cannot be extensive Potato disease without heavy and continued rains in connection with a high temperature. But with either of these conditions alone the murrain does not spread. If it was otherwise, a year notorious for an outbreak of the murrain, and where seed (spores) must have been sown in the greatest abundance, would be followed by another great crop of fungus and consequently disease. But this is not so. Let the disease be ever so virulent, and resting spores be produced in myriads, and that year be followed by ten dry years, the crops will be safe—there will be no disease; but if the eleventh year is a wet year, if rains are protracted and the plants and atmosphere become saturated, and at the same time a high temperature prevails, then will the disease again be of the most violent kind even if no diseased tubers have ever been produced on the same site and in the same soil.

Some years ago I was witness of some careful experiments relative to the Potato disease. A large block of venerable buildings were occupying a low damp position. It was decided to pull them down. The age of the buildings was so great as to date from a period anterior to the distribution of the Potato in this country. Soil (sand) for raising the ground was brought from an Oak wood, which in all probability had been a wood for centuries. This was placed in a heap on the ground and some of it was spread, and the site of the old buildings was planted with Potatoes. The site was still wet—that is, naturally lower and wetter than the surrounding ground. Not a particle of manure was used, and the crop on this "fresh ground" was prodigious. But the month of July was wet and sultry, and the disease was virulent and prevalent, commencing on this wet fresh site, and being there worse than on the older, higher, and drier ground contiguous. But the most striking fact has yet to be mentioned: On that part of the fresh soil that was not spread—a cone-shaped heap in the centre, which was also planted with Potatoes—there was no disease. There was the disease all round, even to the extent of destroying the crop, and yet on the cone-shaped heap every Potato was sound. There the soil was not saturated, the plants remained healthy, the sap pure, and no suitable medium was provided for the germination of the disease-spores. They were not in the site, neither were they brought in with the soil. They must have been introduced with the sets, or have been brought by the wind.

All experience teaches the same lesson. In seasons when disease is rife it is the worst in the wettest and rich soils, and the least severe in upland sandy districts. We learn from this not to manure heavily, and to deeply work and well drain the soil so that superfluous moisture may pass away.

In the instance noted, if the Potato disease was caused by the fungus, the fungus was caused by something else. That "something" was superfluous moisture and excessive heat, rendering, as I suspect, the sap of the plants impure by imperfect elaboration; or why were the plants on the mound free from the malady?

I have seen plants since then on many other mounds free from disease while crops on the surrounding level have been all but ruined. Potatoes do not, therefore, "always take the disease," and further than that I believe they will never take it if extreme wet with excessive heat do not call it into action.

We are brought now to the conclusion that has been so frequently advocated in the pages of this Journal: We cannot control the weather, but we can in a great measure the crops. We can plant kinds that mature early, and thus steal a march on the elements and save our crops from the rains and heats of July. That is what practice teaches, and in corroboration there is the fact that I have not had a diseased Potato in my early crops for twenty years.—A. N. G., *Lincolnshire*.

### OSMASTON MANOR CUCUMBER.

I HAVE grown this variety of Cucumber in a house with several other sorts, and I find it excellent. The plant is a free-grower and produces an abundance of fruit. These are not only of a large size, but are handsome in appearance, and the flavour is very good. The fruits also keep green longer than those of any other variety—in fact, they do not appear to "go yellow" at all. On that account this Cucumber may

be useful for certain purposes, and I believe it to be worthy of notice. I do not, however, consider it quite the best Cucumber in cultivation, for, taking into consideration all points—size, appearance, free cropping, and quality, that honour I must award to Tender and True. Osmaston Manor is nevertheless an excellent variety, and for keeping purposes is the best I have grown or seen.—A MARKET GARDENER.

### ROYAL HORTICULTURAL SOCIETY.

At a meeting of the debenture-holders of the Royal Horticultural Society held on the 1st inst. Mr. Edgar Bowring took exception to a statement we made at page 74, in which we remarked, "As it is well known that there has not been, except in two or three years, any surplus receipts from the gardens, the payment of debenture interest was manifestly most culpable." Mr. Bowring said, "At all events the minutes of the meetings show that up to the last three, or four, or even five years the interest was honestly and fully earned, and therefore to the statement that it was improperly laid out, that I think is a sufficient answer."

Now we do not know what the minutes of the meetings of the Expenses Committee show, nor do we know what statements of accounts were submitted to the Committee, but we are content to accept Mr. Bowring's statement as perfectly correct from what was within his knowledge. Our statement was made from facts gathered from the printed accounts of the Society, which were distributed annually among the Fellows. These accounts show the income and expenditure of the Society for the year, and it is from the surplus receipts of the year that the debenture interest was to have been paid. Let us now see from the following statements whether or not the surplus receipts were sufficient to pay the interest, and that the Council were justified in doing what they did.

In 1862, the year of the Great Exhibition, the Society paid the full amount of rent to the Royal Commissioners for the year, and the full amount of rent in advance for 1863, leaving a profit of £1013 11s. 7d.

	£	s.	d.	£	s.	d.
1863. Liabilities .....	1433	5	8			
1864. Liabilities .....	3546	4	7			
Due to Treasurer .....	2784	10	3			
Deficit after paying interest .....				6390	14	10

In this year the life compositions were sold to meet the deficit, and yet the debenture interest was paid out of surplus receipts!

1865. Liabilities .....	369	2	8			
1866. Liabilities .....	980	10	4			
Balance contra .....	263	17	7			
Deficit after paying interest .....				1134	7	11
1867. Liabilities .....	300	0	0			
Balance contra .....	878	0	11			
Deficit after paying interest .....				673	0	11
1868. Liabilities .....	1166	7	10			
Balance contra .....	1179	5	10			
Deficit after paying interest .....				2945	13	8
1869. Liabilities .....	2409	12	10			
Balance contra .....	1331	18	11			
Deficit after paying interest .....				8741	11	9
1870. Liabilities .....	1592	1	7			
Balance contra .....	1813	9	6			
Deficit after paying interest .....				2905	11	1
1871. Liabilities .....	1597	0	3			
Balance Cr. ....	155	15	0			
Deficit after paying one year's rent and interest .....				1441	5	3
1872. Liabilities .....	1865	4	1			
Balance contra .....	876	19	9			
Deficit after paying interest .....				2242	3	10
1873. Liabilities .....	3487	6	1			
Balance contra .....	1136	1	2			
Deficit after paying interest .....				4623	7	3

1874. It is impossible from the published statements to arrive at what the actual receipts and expenditure really were in this year, for it is well known that entries were made of payments under the head of expenditure which had never been made.

1875. Balance contra ..... £3210 16 11

It appears, therefore, that in no year since the Society entered into the agreement with the Royal Commissioners have the surplus receipts ever been sufficient to pay the debenture interest except in 1862.

### SIR J. PAXTON STRAWBERRY.

My experience of it here may be of value. Last year I had fifty plants and forced them; they did fairly well. I raised

a hundred from them, and obtained the largest, particularly forced Strawberries, I have ever seen. Some few were 2½ inches by 1½ inch, and of proportionate thickness. I planted out the plants from which the runners were obtained that produced the fine fruit, and they have been perfectly barren. Other old forced plants of other varieties treated similarly have borne well.—EDWIN CHILD, Gardener to J. P. Heywood, Esq.

### ROSES UNDER DIFFICULTIES.

A BROTHER of mine who lives in the West Riding has for years been cultivating Roses, and until this year has had most indifferent success. His rosery lies very low, not far from a running stream called in Yorkshire a beck, which is the receptacle of every kind of filth. He is surrounded by mill chimneys, and the climate is severe. But, on the other hand, he has a magnificent soil, I should say there could be no soil more suitable for Rose cultivation. The frosts there continue so long that they often cut back his plants after the Crystal Palace Rose Show is over; this year, indeed, on the 4th of July the thermometer was only 3° above freezing point.

Year after year have I been to see his Roses, and have always been disappointed, but this year he has had some very fine blooms. I staged for him a box of twelve Roses for the Brighthouse Show which were exceedingly fine; but unfortunately he had omitted to enter them, so he could not compete; The judges, however, admired them so much that they highly commended them. My object in writing this letter is to help any rosarian who is placed in a similar difficult position by relating my brother's experience.

First, then, the great secret is to prune very late. For years he has pruned early in March, and for years he has failed. This year it was nearly the end of April before he touched his Roses with a knife, and they have done well. The reason is obvious. If you prune early your plants are only just recovered from their stagnant condition or period of rest, and are not sufficiently established to withstand any sudden check, so when the frosts come the Roses are cut down almost to the ground, and have to be pruned again; but if you leave them the frost kills the tops of the shoots, which the pruning knife would in due course remove, and when you do prune your plants will start at once without being much injured, but only retarded by the late frosts.

Secondly, do not syringe more than you possibly can help. My brother formerly had the hose going all day, but to no purpose; the blacks fastened on the foliage persistently, and he could not keep them under. This year his foliage is comparatively clean and bright, and the growth wonderful. The constant use of water on foliage in smoky neighbourhoods causes the leaves to suck in the smoke and soot, and they are worse than they would be if water never came near them; at least that is his experience, and I give it for what it is worth.

And now as to selection. My brother formerly had all the best varieties, but many would not live; however, some of the very best fortunately stand his climate, and these do very well, notably Mdle. Eugénie Verdier. I have been delighted with this lovely Rose in Yorkshire, also my particular pet "the Baroness." Marie Baumann, Charles Lefebvre, and Louis Van Houtte all do well there; and Général Jacqueminot and Duke of Edinburgh grow like weeds and bloom like Daisies. La France is sometimes good, but she has too much of the China or Tea Rose to do well in the north. Edward Morren does splendidly there, and many others too numerous to mention here.

In conclusion I am convinced that there is no part of England where an ardent lover of the Rose may not cultivate with confidence the queen of flowers, and although as a rule the blooms come too late for the great shows, yet they are in time for the autumn exhibitions.—WILD SAVAGE.

### ALL THE YEAR ROUND LETTUCE.

My garden soil is very light and thin, and the subsoil is gravel, and has not received more than six hours' rain during the past three months. Vegetables are consequently very scarce, and the greatest difficulty is experienced in meeting the demands of the kitchen. Lettuces have "piped" for seed before being half ready for cutting, and I should not have been able to produce salads but for the variety above-named, which has been the only one to "heart" under the extreme heat and drought. I can now cut excellent Lettuces of this variety, while three other sorts growing on the same plot of ground are

worthless. I think this fact worthy of being mentioned, as the information may be useful to others residing in dry districts.—J. B. S., *Clapham Park*.

### THE FLOWER GARDEN AT BISHOPSTOWE.

THIS flower garden is effective, yet simple is its design and the mode of planting. The designs of many flower gardens are so elaborate that the beds can only be formed and their ornamentation carried out by those trained in the advanced school of flower gardening. The flower garden at Bishopstowe, on the contrary, can be "laid down" by anyone who can describe a circle and draw a few straight lines. It is also suitable for being carried out on a large or a small scale. At Bishopstowe it is on a large scale, and the effect very imposing. We have figured only a portion—one-half—of the plan. The design may be carried out to any length desired, the beds being planted in duplicate. The plants, as a rule, are easily raised in large numbers.

*Iresine Lindenii* associates well with Golden Feather, and

up its first shoots as fine as a horsehair, and these are very easily damaged to the ruin of the plant. It is said to be particularly partial to gravel.

I would advise "D., Deal," to plant some on a gravel walk or drive if he can conveniently do so, and in different aspects, and should the summer be particularly dry to water it occasionally (I have left mine unwatered as a test), but, above all, to protect the tender shoots from being hoed-off or destroyed.—H. C. RIPLEY, *Minster Lovell, Oxon.*

SOME years since when travelling in Scotland I was greatly struck with the plant, and on my return I endeavoured to obtain it, but was assured that it would not grow in this part of the kingdom, every attempt to acclimatise it having failed.

In May last a friend brought me a root of the coveted *Tropeolum* from Ayrshire, and I had it planted in a sheltered nook exposed only to the west with a wall at the back, and the root of the plant is protected from the extreme heat of the sun by a piece of coarse zinc wirework, into the meshes of which a few green twigs are loosely interwoven. The ground is kept

Fig. 13.—BISHOPSTOWE—PLAN OF THE FLOWER GARDEN.

#### MODE OF PLANTING THE BEDS.

- |  |   |   |
|--|---|---|
| 1, 1, Centre, <i>Iresine Lindenii</i> , a band of Golden Feather, and edged with blue Lobelia. | 3, 3, Centre, Purple King Geranium, edged with Golden Feather.                                | 6, 6, Centre, <i>Vesuvius Geranium</i> , edged with <i>Tagetes signata</i> pumila.  |
| 2, 2, Centre, Flower of Spring Geranium, edged with <i>Iresine Lindenii</i> .                  | 4, Centre, white Geranium, surrounded with scarlet Geranium and edged with Golden Thyme.      | 7, Centre, <i>Dracena indivisa</i> , surrounded with <i>Eucymus radicans variegata</i> , edged with a double row of <i>Echeveria secunda glauca</i> . |
|  | 5, Centre, <i>Coleus Verschaffeltii</i> , edged with <i>Polemonium carolinum variegatum</i> . |   |

the blue Lobelia surrounding the Pyrethrum is always agreeable. The Flower of Spring Geranium and the *Iresine* are also extremely effective, and especially so is the combination of the two plants, *Coleus Verschaffeltii* and *Polemonium carolinum variegatum*. This design is worthy of attention at this season for propagating plants for future displays.

### TROPEOLUM SPECIOSUM.

IN answer to my friend, "D., Deal's," inquiries, allow me to say that *Tropeolum speciosum* is growing in perfection at Laggan House, Maidenhead. I should think, therefore, that it would grow in Kent. I have seen it in perfection in Perthshire, Selkirkshire, and Roxburghshire, where cold and frost is keen enough for anything. I have a plant established against the wall of this house, due south, in the gravel drive. I brought it from Scotland at the end of June last year. It has never been watered, but has suffered a little from the extreme heat and drought which we have had here for some time.

It has been found difficult to establish at gentlemen's houses in Scotland as well as in England; whilst, perhaps, it was growing in luxuriance at that gentleman's lodge, simply, I believe, because it was let alone at the cottage, but destroyed by frequent hoseings, rakings, and weedings at the gentleman's place. The root is like pieces of round macaroni. It throws

constantly moist by frequent waterings. The plant is now in a perfectly healthy state; it has made a growth of nearly 4 feet, has thrown up suckers, and the upper branches are now covered with flower buds.—E. L. P., *Richmond, Surrey*.

### CALANDRINIA UMBELLATA.

IN the wild race of the horticulturist after novelties, good old things far more worthy of his attention and care are too often heedlessly passed over or altogether ignored. Here is an instance of it. Where in flower ground or in rockwork do we meet at this season a bed or patch of *Calandrinia umbellata*? Echo answers, Where? and yet for striking effect in either situation we scarcely know anything to equal this lowly but dazzlingly brilliant little plant, as it spreads its umbels of lovely flowers in the full blaze of a July sun. If we were to take at this season, and on a fine sunny day, an admirer of hardy herbaceous plants into a choice and most extensive collection of his favourites, and that among the said collection was a patch of *Calandrinia umbellata*, we firmly believe it would be the first to arrest his eye and challenge admiration. We should be glad to see it more largely availed of for summer decoration. For a few pence seed sufficient to raise any quantity of plants may be obtained, and it is most accommodating as to treatment. It is naturally a perennial, and may be grown and treated as such or as an

annual or biennial. Seed may be sown next month or the following, and the plants allowed to winter in the open well-drained dry beds, to which they have transferred from the seed-bed, or they may be potted into small pots, and kept over in a cold airy house or frame for next season's bedding. Like other Portulacaceous plants, it loves to display its beauties in dry exposed spots, and under strong sunshine. The colour of the flowers, rich purple magenta, is intensely brilliant, and the quantity of colouring matter in the stalk of one of its little flower umbels is quite remarkable. One of them placed in a small glass vase will dye the water of a most beautiful magenta tint.—(*Irish Farmers' Gazette*.)

## ROYAL HORTICULTURAL SOCIETY.

AUGUST 2ND.

On Wednesday the 2nd inst. a special general meeting of the Fellows of the Royal Horticultural Society—a summary of which appeared in last week's *Journal of Horticulture*—was held in the Council Room, South Kensington, "for the purpose of hearing a statement by the President as to the financial position of the Society." The chair was taken at three o'clock by Lord Aberdare, the President, who was supported by the following members of the Council:—Lord Alfred S. Churchill, Mr. Henry Webb (Treasurer), Dr. Hogg (Secretary), Mr. Haughton, Dr. Denny, and Mr. Campion. There was a large attendance of Fellows, and amongst them were the Hon. C. S. Butler, Mr. H. Guedalla, Mr. Grote, Mr. Dyer Edwards, Mr. Liggins, Mr. Barr, Dr. Masters, Mr. Shirley Hibberd, Mr. I. I. Wheble, Mr. S. H. Godson, Mr. Alfred Smee, Mr. Godwin, Mr. Edgar Bowring, Mr. J. Lee, &c.

The President said:—When last we parted in this room, ladies and gentlemen, it was in the hope that through restored harmony by means of a common and united effort we should be enabled to provide a sufficient income for the maintenance and support of the Society. We thought the Royal Commissioners would assist us, and they did make offers of assistance, accompanied no doubt by certain specific conditions. The Commissioners made offers to the Society, giving us, so to speak, three years' grace as to rent, but binding us to have raised, or to exert ourselves to raise, during those three years the subscriptions to the amount of £10,000, which would have been ample for all purposes. Well, animated by the appearance of restored good feeling on all sides, we exerted ourselves to the utmost to raise the subscriptions to the amount of £10,000 annually; but I now very much regret to have to state that the result has not answered the expectation we had when last we met, or the hopes we certainly held out to the Fellows. We have received since the beginning of the year about £4500, and we have now in hand only the sum of £1000 to enable us to carry on until the close of the year, and in order to do that we must very materially reduce our expenditure, so that we shall close the gardens without dishonour. Committees have been appointed both by the Royal Commissioners and by the Society, but, unfortunately, they have never met. Well, under all these distressing circumstances we addressed the following letter to the Secretary of Her Majesty's Commissioners of 1851:—

"Royal Horticultural Society, South Kensington, S.W.

July 25th, 1876.

"SIR,—I am directed by the Council of the Royal Horticultural Society to inform you that their efforts to raise subscriptions sufficient for the maintenance of the gardens have failed, and that the amount obtained will not enable them to continue their present expenditure to the end of the year. Under these circumstances they would have been prepared to surrender the lease of the gardens at South Kensington to the Commissioners if they could have done so with propriety and safety to the Society. They are, however, advised that the debenture-holders, whose only security for the payment of their interest is the continued maintenance of the gardens, may object to this surrender, and may take legal measures to prevent it.

"This being the case, the Council have decided upon holding a meeting of the debenture-holders on the 1st August, and of the Fellows of the Society on the 2nd August, in order to acquaint them with the position of the Society, and to inform them that the Society may be compelled in future to abstain from all expenditure on the gardens, and virtually to close them.

"The Council, however, are unwilling to take this grave step without previously informing the Commissioners of their intention to hold these meetings.

"I am also desired to add, that the committee of the Council which was appointed to discuss with the committee of the Commissioners any arrangements for the future which it might be expedient to make, is prepared and desirous to meet your committee on as early a day as possible.—I have the honour to be, sir, your obedient servant, ROBERT HOGG, Secretary.

"Secretary H.M. Commissioners, Exhibition of 1851."

Now that being the state of the case let me say one word as to the cause of it. One gentleman in a very short sentence, yesterday at a meeting of the debenture-holders, suggested that the Society was unable to carry on its proceedings because it did not receive sufficient subscriptions. Well, we unfortunately know it is too true. Since the last meeting—and I will gladly bear testimony to the excellent temper shown by the Fellows on that occasion—the fact has been brought out that there is a very great unwillingness on the part of the inhabitants of this

neighbourhood to subscribe anything to these gardens as long as they are connected with the Horticultural Society. It was only the other day one gentleman assured me he had in his possession some three hundred letters from persons who live in this neighbourhood, in which was expressed their willingness to subscribe to these gardens as soon as their connection with the Royal Horticultural Society was severed. That shows pretty well the state of feeling which exists. Then, on the other side of the question, we are also aware that there is no inconsiderable number of persons who take an interest in horticulture, who hold back from this Society so long as it is connected with South Kensington. They think that the interests of horticulture are sacrificed to those of South Kensington [hear, hear]. Whether that be so or not, this feeling is very strong and deep among many horticulturists, and there cannot be a doubt it has been very much increased by the dissensions of last year [hear, hear]. I think you will agree with me that, considering the position in which the Society is placed, the Council have not called you together one moment too early in order that the affairs of the Society may be placed before you. Indeed, you should have been called together sooner if we had not had a hope that those who suggested this union between South Kensington and horticulture, and who are entrusted with a large amount for the promotion of science and art, would to some extent at least do what they have hitherto done. They have decided. They consider they have given us as much assistance as they can. It is not for me to find fault with their decision, but I tell you plainly you cannot look to them for assistance. Well, then, on the other side, we cannot, with only £1000 in hand, meet the ordinary expenditure of the gardens up to the end of the year. In order to carry on the gardens to the end of the year we must reduce our expenditure. Speaking for myself as a resident, I am not without hope that arrangements may be made with the Royal Commissioners under which some portion of the gardens shall be kept as an open space—an ornamental space. The Society, partly through the substance of the unfortunate debenture-holders, spent £73,000 on the gardens. The Royal Commissioners themselves have spent no less a sum than £63,000, and so it seems to me pretty obvious that there has been £140,000 expended on these gardens. I therefore do not think they will be absolutely destroyed, but that some arrangement will be made between the Society and the Commissioners to keep as much of them as an open space as they think proper. As regards the Royal Horticultural Society, I should be extremely sorry the union between the members should end. I should indeed be extremely sorry it should end. I know many persons connected with the Society who are extremely hopeful that if this connection with South Kensington should be dissolved they can start again on a broad basis. No doubt they might maintain the gardens at Chiswick. There is an increasing interest in horticultural subjects. There are a number of persons who bear strong testimony to the services to horticulture rendered by the Royal Horticultural Society. I do hope, however disastrous may be the end of this union which has now existed some fifteen or sixteen years, it will not be fatal to the interests of the residents of South Kensington on the one hand or of the Society on the other. I sincerely hope it may fall to my lot to make a more cheerful and satisfactory statement on some future occasion [applause].

Mr. S. H. GODSON.—My lord, I rise on the present occasion to submit a resolution to the meeting, and it will be something to this effect, that a committee should be appointed—make it as large as you please—to go through the accounts of the Society, and to discover the amount of money advanced to the Commissioners of 1851 for certain works—earthworks and arcades—which had to be carried out under agreements made with the Society. The fact, my lord, is that this Society has paid £125,000 to the Royal Commissioners, who at the time were in want of funds. All these points connected with the accounts, and the money advanced by this Society, should be made the subject of strict investigation by a committee. As to the present Council I exonerate them from all blame for the position in which the Society is placed. I have asserted nothing which cannot be proved. I then beg to move, my lord—

"That a committee of five Fellows be appointed to go through the accounts of the Society to discover the amount of money advanced to the Commissioners of 1851 to pay for certain works, earthworks and arcades, which the latter had to carry out under their agreements with the Society, and which they were not able to pay for in consequence of their being in want of funds at the time, and which sums are still owing by them to the Society.

"That the committee report to the Council the amount so owing, and that the Council shall then at once call upon the Commissioners of 1851 to refund with interest thereon such sums of money so ascertained to be still owing by them to this Society."

I think if that resolution is agreed to and acted upon it will result in some advantage to the Society.

A FELLOW seconded the resolution, and said he thought there was some truth in what Mr. Godson said. At all events the Society's property at Chiswick had been shamefully misused, so that it was really necessary to have a committee of investigation appointed [hear, hear].

The PRESIDENT.—At the present moment I do not know what is the opinion of the meeting on this question. I assure you there is nothing would give me greater pleasure than to find this large sum was due to us by the Commissioners. I am certainly glad to say we have some claim upon them, but it is impossible for me to hold out any hope of there being a successful result to such an investigation as that which has been proposed. At the same time it is not for us to resist any proposal which comes from the Fellows. I would much rather they were freely given to the Council [hear, hear]. I have been informed that the whole of the arcades were built at the expense of the Commissioners, and you heard, no doubt, of the agreements which were entered into. By the first agreement there was, as a matter of fact, £50,000 spent upon the Society. Then £70,000 was raised by life subscriptions, and in addition there was the sum of £60,000, consisting partly of donations, and that was spent upon the capital expenditure of the Society. Then, on the other hand, the Commissioners themselves having expended their £40,000 sought fresh powers to raise an additional sum of money, and it was in consequence of that the annual expenditure, the rent paid to the Commissioners by the Society, which stood at £2145 per annum, was raised to £2400. With regard to the future, that is a question I should be very sorry to refer to, especially as it is impossible to say what the conditions of the future may be. As I take it, there is no use in referring to what was done with respect to the Society ten or fifteen years ago. Let all that be buried; but I am sorry to say, although I can well appreciate the motives of the mover of the resolution, that I cannot hold out to you the very faintest hope that any good—that any practical result will arise from the appointment of the committee of investigation which has been proposed. I cannot see that it will lead to any useful or practical result. It might do some good with respect to small sums, but as to these large sums referred to by the mover of the resolution, I cannot hold out the slightest prospect of any substantial result—any substantial benefit coming from the adoption of the resolution, which, I have no doubt with the very best intention, has been submitted to you. It is, however, for you, gentlemen, to say how far it meets or does not meet with your approval.

Mr. H. GUELLA.—My lord, I take it that we are met here to protest in the strongest manner possible, to protest against these magnificent gardens being closed without an effort—a great effort on our part [hear, hear]. The recommendation submitted to you now is that a committee of the whole house should be appointed in order to have—not a committee of five only, but a mixed committee, composed of horticulturists and residents of the neighbourhood. “In a multitude of counsellors there is wisdom” [hear, hear]; and this committee could very well consider whether we should separate the Chiswick Gardens from the South Kensington connection, and also report upon the nature of the attractions which would be likely to ensure to us an increase of revenue. It is, I must say, a very astonishing thing that a kindred institution to this is able to keep itself above board, I mean the Botanical Gardens, and that chiefly through the influence of Prince Teck. These gardens of ours are totally neglected by royalty [hear, hear]. I am sorry to say that, in consequence of a vote given against the Council some years ago, we turned royalty against us. Why in a learned society like this should we not be received by our worthy President? I should be glad, my lord, to see you holding a reception. I consider you cannot discuss the improvements it is necessary to make in our arrangements until the Fellows are prepared to talk the matter over, and that can best be done by a committee. I hold that we should not, after an existence of twenty-five years, allow the gardens to be closed, especially as, if the matter was calmly discussed, we must eventually get money from the Commissioners. From many points of view it is most desirable that these gardens should be kept up [hear, hear]. For my own part I always had a shrewd suspicion that the Commissioners had ulterior views with respect to these gardens [cries of “hear” and applause]. I think that in conjunction with the debenture-holders—and I think we should cement a union with them—and with the residents in the neighbourhood, and by providing proper attractions we would gain an immense increase of revenue; and if there was any possibility of our working in unison with the Commissioners, through which we would be again favoured by royalty, in a few seasons we should be all right again. Something has been said as to the sum requisite to keep the gardens up to the end of the year; I should like I know what that sum is.

The PRESIDENT.—At the present scale of our expenditure, I think the sum requisite would be about £2000.

Mr. GUELLA.—Well, that is a very serious sum of money. I should propose that a committee of nine, composed of the various classes of horticulturists and Fellows, be appointed for the purpose of a general investigation of the accounts and affairs of the Society, and of securing to us these gardens.

The PRESIDENT.—I wish at once to say this. I hope the meeting will disembarass themselves of the idea that there is any desire on the part of Her Majesty's Commissioners to obtain

possession of these gardens. If there is anything they are anxious for in the matter, it is that the Royal Horticultural Society should flourish and fulfil the original intention of its founders; but, as to the possession of the gardens, I can assure you it is not a question with them at all. My belief is that the Commissioners would like to open a sort of square. Now, in a very good-tempered sort of way, a gentleman suggested that the Fellows did not see as much of the President as they desired; but I am informed that only on one occasion was there a reception of royalty, and that was unfortunately in the absence of the President.

Mr. LIGGINS.—I assure you, my lord, I have had the opportunity of being received by his Grace the Duke of Buccleuch.

The PRESIDENT.—Everyone who knows the extreme courtesy of the Duke of Buccleuch must feel what a pleasure it was to have been received by his Grace, but I was told at the Council there was but one attempt made at a “reception.”

Mr. LIGGINS.—I remember the reception by the Duke of Buccleuch as well as I do seeing your lordship to-day, and our most honoured guests were the Prince of Wales and the Duke of Edinburgh.

The PRESIDENT.—Oh, that is quite sufficient. You state to me what you saw, and that is worth fifty other statements which perhaps are only mere rumours.

Mr. GODWIN.—I should like to ask your lordship whether the Council have prepared any definite plan to lay before the Fellows.

The PRESIDENT.—The Council have done their best, and have no further proposal to make.

Mr. GODWIN.—In that case there is nothing farther to be done but to appoint a committee and go on with the business ourselves [hear, hear].

The PRESIDENT.—The question before the meeting now really is whether the committee proposed is to be appointed.

Several FELLOWS.—No, no.

Mr. SHIRLEY HIBBERD.—Why should such a committee be appointed? Its deliberations would lead to nothing [hear, hear].

The Hon. C. S. BUTLER.—As the statement made by your lordship evidently expresses the unanimous opinion of the Council I think to appoint a committee would be simply stepping out of the frying-pan into the fire [cries of “hear.”]. I do not think any committee could make a better business of the matter than the Council. The appearance of the gardens is more like that of a cemetery than of the gardens of a horticultural society [a laugh]. They looked as if we were determined to die respectably [laughter]; and undoubtedly it is better to die in a quiet and respectable manner before disgrace is brought upon us [hear, and a laugh]. Therefore to appoint a new committee would be of no earthly benefit [hear, hear]. The only way is to die respectably. Let these gardens be made public gardens, and not have them gardens which must cast gloom and melancholy upon anyone unfortunate enough to go into them [laughter]. It does not appear that your lordship or the Council have any proposition to make to us.

The PRESIDENT.—I have distinctly stated what is the policy of the Council, and, moreover, I have stated that the Council have no feasible proposal to place before the Fellows.

Mr. C. MORGAN.—One great result, my lord, will be obtained from what we may call the crisis which has taken place, and that is that we shall feel it incumbent on us to make a great effort to keep these gardens, at least for the use of the inhabitants of the neighbourhood. I feel that some further exertions should be made by us, and if nothing better is submitted to us I should certainly vote for the suggestion of the honourable proprietor to appoint a committee.

Lord ALFRED S. CHURCHILL.—The Chairman has explained to you the financial position of the Society. The ordinary expenditure of the Society has hitherto been something like £5000 and over or £6000. You have got £1000 left, and of course it will be the object of the Council to spin that amount out to the end of the year as well as we can; but even then, in order to keep the gardens going, we must make a great reduction in our expenditure. I may say that the gardens will not be actually closed [hear, hear], and that one entrance—one only—will be kept up. The expenditure on the gardens will be reduced to a minimum—of course it must be. I should like to observe that at the time your Chairman made an appeal to you some months ago our average income amounted to about £7000, or indeed I may say a little over. By the noble Chairman's appeal it was proposed to raise the income of the Society to £10,000 a-year in accordance with the arrangements made with the Commissioners, and although the meeting to which I refer was strongly in favour of this course, there was great difficulty in even attempting to carry out the proposition; and for this reason—that when it came to the point nobody could be found willing to go round to the houses, because there had to be made a sort of *ad misericordiam* appeal, and the result was that many members left the Society and sent in their resignations. I was induced to join the Society, but I joined it from a horticultural point of view, and I thought at the time that the period had arrived when an absolutely strong alliance would be cemented between horti-

culture and South Kensington. At the present moment our position is this: We have informed the Commissioners that we are unable to go on, that our expenditure must be reduced, and that we are willing to surrender the lease of the gardens to the Commissioners, provided we can do so with honour to ourselves [hear, hear], and in a manner in some way satisfactory to the debenture-holders who are by far the most pecuniarily interested persons in the transaction. If the Commissioners would only come to terms with the debenture-holders the Council would surrender the lease. We are willing to do so, no matter what it costs [hear, hear]. What is our object? It is to start again with Chiswick, with this difference—that we should be determined to make the Society an absolutely pure horticultural society instead of a local one [applause]. I wish to point out that we have got no definite resolution to lay before the meeting, as we are waiting for the Commissioners to settle with the debenture-holders. If they do not do so, we who spent the money will be drifted into bankruptcy, and then no one will get anything at all; and all others connected with the Society will suffer unless pressure is brought to bear upon the Commissioners to settle with the debenture-holders.

Mr. GUEBALIA.—We must have a meeting to propose our dissolution.

Lord A. S. CHURCHILL.—We cannot propose our dissolution until we find what the Commissioners say. We must call you together again.

Mr. ALFRED SMEE.—I quite agree with Lord Alfred Churchill that there never was wanted more than now a national horticultural society [hear, hear]. It was never more needed than now that if the Horticultural Society is to be maintained in its proper position we must dissolve our connection with these gardens. We have something like 17 or 20 acres. How are we to dissolve our connection? It is quite true that since we have had this amalgamation the whole affair has been an entire failure. I really do not blame anyone for it. The experiment was tried with the best of intentions, and the Commissioners thought that horticulture exhibited within these buildings would constitute this a useful place of resort for the residents of the neighbourhood. That has been an entire failure, and I am rejoiced to find the Council are determined to take those steps by which we may act as a national horticultural society [applause]. Without horticulture there can be no horticultural society [hear, hear]. The sooner we are dissolved from this connection the better. The Commissioners asserted that a large amount of money has been spent on the Society. Well, the money was spent upon the decoration and ornamentation of buildings around us. What would they be only for them? but are we to pay for these stucco figures? What have they to do with horticulture? I do say that wherever these gardens may be, an important obligation devolves upon us—viz., to keep up a national horticultural society [hear, hear]. In every country in Europe there is such a society, and this is the only one mixed up with nurserymen. I hope and trust, my lord, you will take every possible means to have this question settled by severing our connection with South Kensington [hear, hear].

A FELLOW.—We all knew that when we laid out our money there was nothing here but gravel. The value of the gardens has been doubled and trebled. It was very hard on the debenture-holders that their money should have been laid out for the benefit of the residents in the neighbourhood.

Mr. LIGGINS.—It is very hard, no doubt, that those who live in this neighbourhood should be deprived of the use of these gardens and of attending the flower shows of the Royal Horticultural Society, but I can look back to bygone times when this was purely and simply a scientific Society. It was to revivify the Society that the union was brought about. That being the case, I think it only requires a large amount of money to come in to enable a really good management to make the Society prosperous. Indeed it was prosperous and successful pecuniarily up to a short time since. What is the reason that royalty never shines upon us? It was thought we should see the Prince of Wales amongst us upon his return from India. He would have got a hearty reception from us, but he has not come. It cannot be that His Royal Highness has any dislike to the Horticultural Society, or that he has been surfeited with the flowers of India. We ought, at any rate, to make a great effort to save our position, and therefore I think a committee ought to be appointed.

The PRESIDENT.—I now put to the meeting the motion that a committee be appointed to go through the accounts.

The resolution was then put, and lost by an overwhelming majority.

The Hon. C. S. BUTLER.—My lord, I am an original shareholder of this Society which I have seen gradually decline, but for that result I do not blame anyone. As to think of canvassing people, no doubt friends to the number of twenty, thirty, or forty might be got, but then hundreds more would not set matters afloat. It takes thousands of people to meet the expenses of the Society, and it will take more than any amount of canvassing will do to get back that which we have lost. I am

really of opinion that horticulture will profit by the dissolution of the connection which is now contemplated. It is, therefore, that with pleasure I beg to propose this resolution:—

"This meeting approves the policy of the Council in endeavouring to effect a separation of interests between Her Majesty's Commissioners and the Royal Horticultural Society upon equitable terms with the debenture-holders and life Fellows, and requests the Council to urge an early settlement with Her Majesty's Commissioners."

Mr. SHIRLEY HIBBERD.—I beg to second that motion, and I do so in the hope that it will bring about a speedy dissolution of the arrangements between this Society and the Commissioners [hear, hear]. Over and over again it has been proved that oil and water will not mix unless some medium be combined with them. In our case the requisite medium wanting was the medium of sympathy, which would have brought the two classes together; but we have found no such medium, and so the conflicting elements can never be united [hear, hear]. We must take the world as we find it. For my own part I am not disposed to blame the inhabitants of this district for not supporting the gardens, and I think it would be as well not to cast any blame on Her Majesty's Commissioners. The best thing we can do is to gather up our traps and take our departure to some more congenial clime [hear, and laughter]. There is no use in us talking of canvassing or appealing to royalty. This Society, if it is to live, must live upon its merits [applause]. We have had the experiment of connection with the Commissioners tried. We have been well represented on the Council [hear, hear]. In the midst of many difficulties which have arisen we have had some exciting and unpleasant debates in this room, but from first to last we have been well represented. From first to last our Council must have had much more work and anxiety than any body of gentlemen would undertake except by being well paid for [hear, hear]. They have done their best in the interests of the Society. There is but one course open to us now, and that is to see once more—believing in our horticultural functions, in their truth and entirety, and trusting to what the process of time may effect—to see, I say, what we shall do in the future [hear, hear]. As to the effecting a separation, that is a matter this meeting cannot settle. It is for the Council to lay down proposals under which the separation of interests would be effected, and therefore, my lord, we are bound to impose this task upon your lordship and the Council. Certainly there is no glory to be gained out of it. I feel assured our Council will make the best terms possible to have the debenture debt cleared away [hear, hear]. Let us see that disposed of honourably. It is a happy circumstance that in other respects the Society is not in debt. There is not a penny owing by it [applause]. I feel assured that so soon as we are removed from South Kensington the Society will become really useful to the science of horticulture generally [hear, hear].

The PRESIDENT.—The resolution proposed so exactly, so precisely, represents what the Council have been about for the last two years without success. The resolution expresses exactly what we wanted to do when we saw it was not possible to gain sufficient means to support the gardens. We saw it was necessary a separation should take place, and we were very anxious in addressing the letter read for you to the Commissioners that the two gardens should be separated. We took legal advice upon the question, and found separation could not take place without the dissolution of the Charter, and that that dissolution could not take place as long as the debenture-holders had a lien upon the gardens; so that unless the debenture-holders are satisfied I do not see how a legal termination can be put to the Charter. I do not at all see how that is to be done. At the meeting of the debenture-holders held yesterday in this room a committee was formed, but with what result I cannot say. If the debenture-holders pressed their claims upon the Commissioners, and some equitable settlement was come to, the Society might start upon a new basis; but there is at present a serious legal difficulty in our way. It would be just possible for us to accept the resolution before the meeting, but I cannot hold out any hope that we can do more than we have done. We have no objection to the resolution because, as I said, it represents our policy exactly. I think we have done as much as we can do, and I assure you I should rejoice were I able to say we possessed more hope than we have of a successful result to our efforts [cheers].

A FELLOW.—Will your lordship let us know what is the proposition of the Council?

The PRESIDENT.—What is now before you represents it [applause].

The FELLOW.—Then is the resolution satisfactory to the Council?

The PRESIDENT.—I have no objection to receive it, but I do not hold out any hope of action being taken on it.

Lord A. S. CHURCHILL.—One thing the resolution may do, and that is to strengthen our hands [hear, hear].

Mr. WM. HAUGHTON.—There is one fact which ought to be kept before the minds of the Fellows, and that is—if you desire to abandon these gardens it will be necessary to get the consent

of the debenture-holders to do so. Without that consent we cannot stir one step, and even if we could it is open to doubt whether the debenture-holders could not follow us, as far as their claims are concerned, to Chiswick gardens. That is the legal position of the question. As to practical action, the Council do not see their way to go to the Commissioners and ask them to take any. The Royal Commissioners have positively declined to take upon themselves the burden of the debenture debt. The negotiations tending to that result have fallen through, and whether they will be re-opened or not we cannot say, but under the circumstances by which you are surrounded the first thing you have to do is to make up your minds either to keep these gardens or to lose them altogether [hear, hear]. One thing is certain, that if you want to keep the gardens you must put your hands in your pockets, or you must give a guarantee to provide for the expenses of the year 1877. With the sum of £4500 actual subscriptions we cannot go on with the maintenance of the gardens for next year, and you should understand that the meaning of a guarantee is that each person puts down his or her name for a certain sum, which he or she guarantees to be responsible for. If it should unfortunately happen that no more new subscribers should come in, the guarantors for the sum of £4500 would have to pay the whole of it. If you really do wish to appoint a committee, do not appoint one to investigate matters which have been looked into over and over again [hear, hear], but appoint one whose duty it will be to see how you can raise the money to keep the gardens next year. If that is not done we must only shut up the gardens.

After a short desultory conversation the resolution was carried with a couple of dissentients, and amid some cheering.

A FELLOW asked the President how it was proposed, in case of dissolution, the interests or tastes of the two classes of Fellows—the horticultural and the resident, should be consulted?

THE PRESIDENT.—It will, I believe, be open to the two portions of them to take two different courses—that is to say, the horticulturists proper can form themselves into a society for the promotion of horticulture, whilst the inhabitants of this neighbourhood can place themselves in communication with the Commissioners and see whether these gardens cannot be kept up. It seems to me that is the only course to be pursued by either party. I should mislead you if I led you to think that by anything we could do we could get the inhabitants of this neighbourhood to do anything more for the maintenance of the gardens. For myself I know a number of gentlemen who have done their best in the business, but the disaffection and dissatisfaction are so deeply seated that there is no chance of anything further being done. We are doing the best we can in closing this connection, to close it not with discredit [cheers]. In the meantime all we can do is to keep the Horticultural Society afloat by our own efforts and those of the Fellows. As far as I am concerned myself I am largely interested in this locality; but quite apart from that I shall be most anxious to do all I can to keep these gardens for the benefit of the neighbourhood, which would suffer a great deprivation were they closed [loud cheers].

MR. S. H. GODSON.—Gentlemen, I rise to propose a vote of thanks to our Chairman for his able conduct in the chair as our President, not only on this but on many former occasions, and with respect to whom it is difficult to say whether his ability or great courtesy is the more deserving of admiration [cheers].

MR. BATEMAN.—I have very great pleasure indeed in seconding the vote of thanks, and I do not think any man in the kingdom could have occupied the position of Chairman of this meeting more dispassionately, more courteously, or more thoroughly honestly [cheers].

The motion was put by the mover, Mr. Godson, and carried with expressions of hearty assent.

THE PRESIDENT.—I thank you very heartily, the more so because it is not very often that a society on the point of dissolution gives to its President a vote of thanks. It is, I can assure you, very pleasing to me that it is so. We have exerted ourselves to the utmost to prevent this catastrophe, and if we have failed ours is not the fault [applause].

Thereupon the meeting terminated.

### FLOWER SHOW AT HEWORTH.

FINE weather only was required to make the third annual exhibition of the Heworth Horticultural Society, which was held on the 2nd inst., by the kind permission of Mrs. Starkey in the grounds of Tang Hall at Heworth near York, a complete success. Through the strenuous and untiring efforts of Mr. R. H. Feltoe, the Honorary Secretary, this Society has gained during its short existence a foremost place amongst local shows, and although last year's show was one of the most successful held in this district, yet it is thoroughly eclipsed by the exhibition of this year. Mr. Feltoe and the Committee gathered together a numerous and excellent collection of plants, flowers, fruits, and vegetables. The entries were about double those of 1875, and

comprised 118 classes, all of which, with the exception of about thirteen, were fully represented, in many instances there being as many as five and six competitors in each class. The marquee was crowded in every part, some of the plants being arranged under the higher stands. All the plants and flowers shown were for competition. There was a splendid display of plants, and occupying a conspicuous position in the centre of the tent were a number of beautiful Ferns. For the President's (Captain E. C. Starkey's) special prize for collections of eight exotic Ferns there were four entries, each of which was excellent. Mr. R. E. Noble, Clifton Lawn, York, obtained the first prize, and Mrs. Starkey of Tang Hall was awarded the second. British Ferns were also a capital show, as were also the Lillium lancifolium. The Geraniums were a very fair lot, the double-flowered Geraniums being especially worthy of commendation. In the Coleus classes there were many specimens exhibited, the colour of which was richly shaded, especially that of those belonging to Mr. Noble, which were very beautifully tinted. Decorative plants were also good. The specimens of cut flowers were numerous, and altogether the show in this department was most creditable. There was only one collection of eighteen Dahlias in the marquee, but this was fairly good for the season. The Roses formed an excellent show. Taken altogether the different varieties of fruit were well represented, while vegetables were of a really excellent description. The exhibits forwarded by the cottagers were creditable throughout, and if they excelled in any portion more than another it was amongst the vegetables.

### A WEST RIDING FLOWER SHOW.

"LOVE surmounts all difficulties." Such was my conviction as I saw the really wonderful display of flowers brought together at the Brighouse Horticultural Society's annual Show. The difficulties of cultivation are so great in that district that nothing but the most persistent labour, inspired by the most ardent love, can overcome them. Smoke day and night proceeding from hundreds of mills, poisonous vapours from numbers of chemical works, a naturally cold temperature, long winters, prolonged often till the middle of June—all these combined and many others make the pursuit of horticulture a most arduous one. And yet I know of no district where flowers are more loved, and where better results are obtained, at least from plants under glass.

The exhibition of stove and greenhouse plants at Brighouse, both in the open and amateur classes, was equal to anything I have yet seen, except at the London, Exeter, and Taunton shows. Mr. Joseph Fox of Clayton near Bradford took the first prize for eight splendid specimens. His *Dipladenia amabilis* and *Allamanda Hendersonii* reminded me of those staged by Messrs. Lucombe & Pince at Exeter. *Vinca oculata*, too, was shown wonderfully well, and also *Stephanotis floribunda* and *Bougainvillea spectabilis*. In the amateur classes some very fine specimens were shown. I was talking to the man who won the first prize for six stove and greenhouse plants, and asked him whether he was not a gentleman's gardener. "Nay, I am nobbut a tinner." "A tinner?" "Yes, I live at Mirfield, in a little place near the station." His name is James Manchester, and from a very small greenhouse he brought *Stephanotis*, *Dipladenia amabilis*, *Vinca oculata*, and *Allamanda Hendersonii*, which were wonderfully good. All honour to him and such as he, who, instead of spending their money in the public house, save it up till they can build a little glass house which will defy the climate of the north and enable them to have flowers all the year round.

I was very much surprised to see several good collections of Hollyhocks staged, for the red spider had made such raids on these flowers last year that many nurserymen were unable to send any plants out this spring; but here we had these flowers shown in perfection. *Verbenas*, were, however, very weak. After seeing Mr. Charles Turner's marvellous blooms at South Kensington it was hard to believe that the trusses exhibited here belonged to the same class of flowers.

The vegetables were very fair, but were not so good as I expected to see. The Committee accepted any number and kind of extra prizes, and a wonderful miscellaneous collection of articles these were. Among them I saw a whole salmon and two pieces of meat exposed all day in the tent (fortunately the weather was cool), two rocking chairs, a dozen of beer, a piece of cloth, a box of cigars, &c.

The arrangements were much better than last year, and the crowd was enormous. It did me good to see the crowds crushing round the flowers, and to listen to their original remarks was great fun. I never yet saw so enthusiastic a multitude, and the amount of squeezing the people submitted to in order to see the flowers would have finished-off most of our southern friends. The receipts must have been great, and I only hope that next year the Committee will spend more money in prizes for flowers and less in cups for horses, and brass bands. The Committee of course know their own neighbourhood best, but I am confident

from the enthusiasm which the visitors evinced for the flowers that the Brighthouse Horticultural Society could stand on its own merits, and not be what it is now—an *olla podrida*.—WYLD SAVAGE.

### MOMORDICA BALSAMEA.

THE above is the name of the specimen submitted by "D. T. S.," and of which we are able to give a figure. It is as our correspondent suspects that the plant has no particular claims to beauty, and is seldom to be found in this country except in botanical collections. It is a stove plant belonging to the family of Cucurbitaceæ, and grows freely in ordinary garden soil in a well-heated structure. We cannot give better information in reference to the Momordicas than the following, which is quoted from Dr. Hogg's "Vegetable Kingdom":—"Momordica balsamea, or Balsam Apple, grows in Syria, and is famous for curing wounds. The unripe fruit is infused in

Fig. 14.—*Momordica balsamea*.

sweet oil, and exposed to the sun some days till it becomes red. This, applied on cotton to a fresh wound, is esteemed by the Syrians next to Balsam of Mecca. The plant is also used to form arbours. *M. mixta*, called in India Gol-kakra, produces a large, red, and thorny fruit, containing a yellow insipid pulp, totally inert as a medicine, and is occasionally used for food in Bengal. *M. echinata* produces a round fruit covered with bristles, the size and appearance of a large hairy Gooseberry. It is sometimes seen in Covent Garden under the name of Gooseberry Gourd, and is pickled when green, as Cucumbers are, in vinegar."

### THE HAILSTORM RELIEF FUND FOR NURSERYMEN AND FLORISTS.

An energetic movement has been set on foot towards raising a fund for the relief of the necessitous nurserymen and florists, sufferers by the violent hailstorm of Sunday evening, July 23rd. An influential and thoroughly representative Committee has been appointed, of which Mr. John Fraser, Lea Bridge Road, is Chairman; Mr. Shirley Hibberd, Stoke Newington, Treasurer; and Mr. Richard Dean, Ealing, Secretary, and they are now engaged in issuing a circular to the whole of

the nursery and seed trades, asking for subscriptions to the fund. The circular sets forth that the destruction of glass erections, and stock in the form of plants and trees, has been extensive and complete, that many persons in a small way of business are actually deprived thereby of the means of subsistence, and the Committee state that the sum of £4000 will be required to meet the many pressing demands made upon the fund.

Towards this sum Messrs. Veitch & Sons, and Messrs. Hurst and Son, subscribe £25 each; Messrs. Jno. Fraser, and W. Bull, £10 10s. each; while Messrs. B. S. Williams, E. G. Henderson & Son, Nutting & Sons, T. S. Ware, H. Low & Co., Jno. Wills, P. & S. Kay, H. Stroud, Parsons, Rowbridge, Jno. Turtle, Jno. Matter, J. Sweet, Oddy, and W. E. Gumbleton, subscribe five guineas each; and there are many subscribers of two guineas and one guinea, as well as smaller sums. Already over £200 has been subscribed, and the Committee confidently appeal to all charitably disposed persons for assistance under this grievous calamity. Inspections of the damage sustained in most cases have been made, and the results prove much worse than has generally been conceived.

### ASPECTS OF NATURE.—JULY.

"The mead is our study, and Nature our book."

In the early weeks of spring, when the first flowers come to deck the ground with beauty and brighten the bare bosom of earth with blossoms, they are, we might say, petted and made much of. Everyone knows them by name; but as the season advances, and the woods and fields, the hillsides and depths of the valleys, become the habitats of more numerous varieties of flowers, they are not sought out so eagerly, nor are their beauties so well known. They appear in such profusion that all, save the botanist and enthusiastic lover of nature, pass by them, looking upon them only as part of the full development of the floral season, but scarcely knowing one from the other, nor ever dreaming of their marvellous beauty when closely examined. July is indeed the month of the full blush of Flora's matronly charms.

"A gracious mother art thou, kind July,  
Thy lap all laden with most precious things;  
Earth seems to mingle with the distant sky  
That sheds a hallow'd light upon thy wings."

In the deep shade of thickly planted woods the stately Fox-glove uprears its tapering point hung with its many-speckled bells, which send a fairy tinkle forth with every breeze.

In favoured spots in south Devon and many similar places the Flowering Fern grows near at hand, and attains a size and beauty that well entitle it to the distinctive title of *Osmunda regalis*. Not only are the woods full of greenery, but the heaths and commons display their greatest wealth of waving foliage and gorgeous blossom, for now in some districts the Gorse is brilliant with flowers, and their honey-laden nectaries invite the visits of hundreds of busy bees; while the Broom, scarcely less brilliant in hue, will bloom not only on wild lands, but find a resting-place in the clefts of rocks and the mortar of old ruins, where it grows as luxuriantly as its rival the golden Gorse on rich common lands.

While Scotland displays the Broom "yellow and bright as bullion unalloyed" on her hill sides, and the purple of the Heather on her moors, sunnier climes cannot rival the brilliancy of her summer landscape, though the fields be clothed with the gorgeous flowers of tropical vegetation.

"Their groves of sweet Myrtle let foreign lands reckon,  
Whose bright beaming summers exalt the perfume;  
Far dearer to me yon lone glen of green Bracken,  
Wi' the burn stealing under the long yellow Broom."

"Far dearer to me are yon humble Broom bowers,  
Where the Bluebell and Gowan lurk lowly unseen,  
For there lightly tripping among the wild flowers,  
A listening the linnet, oft wanders my Jean."

But with all its beauty and usefulness the Broom must bow before the Furze in respect of colour, perfume, and the amount of honey secreted in its blossoms; and the enthusiasm of the great Linnaeus may well be understood when he saw this latter on Wimbledon Common, as it was some years since, a blaze of gold in a July sun. The Heath is generally associated with the Highlands of Scotland, the home of the grouse; but our own island has many spots where the beautiful purple carpet is spread out during the whole of the autumn season. The Yorkshire wolds, the Cornish moors, and many other parts are scarcely less lovely than the lake and mountain scenery of the sister land.

At this season every spot of uncultivated ground has its complement of vegetable life—its display of bright plants. Those by the meadow and the waterside are less brilliant, perhaps, in colour, but they bear a multitude of flowers which, taken individually, display none the less the wondrous works of creation and the Infinite Wisdom which has created each for a purpose and a place. Among the most striking objects of meadow scenery during the month are the giant Reeds which fringe nearly every stream and river bank and bend their plumed heads proudly over the water. In similar places scarcely less conspicuous, but certainly not so elegant in appearance, are the Teazles, which stand up boldly, bending to neither breeze nor storm; and holding a supply of water in the cup-like base of their leaves, they almost defy the droughts which often dry up the sides of the stream or ditch on which they grow, and leave the water but a silver thread between the parched banks.

Beneath the shade of the Reeds the exquisitely scented Meadow-sweet is generally to be found, less brilliant in colour than the Creeping Jenny and azure blue Myosotis, which are still to be seen beneath the umbrageous shade of the many varieties of aquatic plants fringing the banks of streamlet and lake. The Meadow-sweet is dear to everyone, for its delicate cream-coloured flowers seem to have caught the sweetest perfume of the new-mown hay so recently cut in their vicinity. But perhaps the most striking of all our native weeds is the giant Hemlock, which is at the present time in the very zenith of its beauty, its magnificent deeply lacinated foliage rivaling the rich leafage of tropical forests, and its large handsome umbel of white flowers being in keeping with the size of the leaf.

Along the hedgebank the wild Bryony twines its graceful glossy foliage up the stems and branches of Hawthorn and Briar, and these display its pale green blossoms, which are scarcely noticed nor give any promise of the handsome cluster of berries the plant will display later in the year. A long season of dryness during this month fully realises the poet's description—

"Deep to the root  
Of vegetation parch'd, the cleaving fields  
And slipp'ry lawn an arid hue disclose.  
Echo no more returns the cheerful sound  
Of sharp'ning scythe."

The cattle also feel the oppressive heat, and

"On the grassy bank  
Some ruminating lie; while others stand  
Half in the flood, and, often bending, sip  
The circling surface. In the middle droops  
The strong laborious ox of honest front,  
Which incomposed he shakes; and from his sides  
The troublous insects lashes with his tail,  
Returning still.  
In rueful gaze the cattle stand."

In Derbyshire and the northern counties the children now go forth in merry parties, can in hand, to gather the fragrant harvest of wild Raspberries, which, if not so plentiful as that of the Blackberries they will seek later on, is fully appreciated by the careful housewife, who finds the luscious fruit no mean addition to the produce of the Currant and Gooseberry bushes of her garden.

So long is the list of wild flowers of July that we cannot essay even to enumerate them, but the wild Clematis or Traveller's Joy deserves a word, covering as it does in many places every hedge in our southern and midland counties, growing often in close companionship with the wild Hop. They garland together the quickest fence and stems of hedgerow trees, and form a graceful feature in the wayside landscape. Clematis, besides its common name of Traveller's Joy, bears also that of Virgin's Bower, both being accounted for by Gerard in the following manner:—"Traviler's Joie is this same plant termed as decking and adorning waies and hedges where people travell; Virgin's Bower, by reason of the goodly shadowe which they make with their thick bushing and climbing, as also for the beantie of the flowers, and the pleasant scent and savour of the same; and by country folks 'Old Man's Beard,' from the hoary appearance of the seeds, which remain long on the hedges."

The corn fields, which are now so golden in the sun, are full of bright flowers, which we shall be better able to identify when the harvest is cut and the many-coloured flowers rear their heads above the stubble; but in the woods, and even in shady spots on heath and moor, the gentle Woodruff may still be gathered, though none, save those acquainted with it, would stoop to gather so small and inconspicuous a flower. Our

grandams, more versed in Nature's lore than we, never neglected to gather a store of this plant for the sake of the perfume it emits when pressed, a perfume which is only perceived after the plant has been gathered.

The Ferns are now in full beauty, the common Bracken filling up the woods and covering many a common and wild expanse, forming a covert for the hare and the timid young of the fallow deer.

"Ferns that grow the stream beside,  
Where the leveret loves to hide,"

are among the most elegant and graceful forms of native vegetation;—but Ferns are as various in their habitats as they are in their beauty. We have the graceful and well-marked Beech Fern and the broad Hart's Tongue; the elegant Maiden-hair, which affects moist places and finds a congenial home at the fall of "The Lady's Well" on the borders of Dartmoor, and the common Polypody which grows in every county, and is most frequently seen near the habitations of man, on old walls, and the broad banks that divide some fields, and finds a home in the fissures of old trees, Hazel or Thorn stumps, and similar places.

Although less noticeable and less sought after than the Ferns, the numerous Mosses now carpet as with a velvet pile the damp woods, and clothe with verdure every moist spot where they can find a resting place. During the dewy eves that generally mark the close of warm July days the merry chirrupings of the nimble grasshopper are heard in place of those songs with which in spring the birds were wont to make night musical. Nor does the grasshopper sing a vesper song only; in the early morning before the sun has risen the merry insect is abroad to greet the wakening day with his cheerful notes.

"The poetry of earth is never dead;  
When all the birds are faint with the hot sun,  
And hide in cooling trees, a voice will run  
From hedge to hedge about the new-mown mead.  
That is the grasshopper! He takes the lead  
In summer luxury; he has never done  
With his delights, for when tired out with fun  
He rests at ease beneath some pleasant weed."

The lady-birds are now engaged clearing the Hop vine of the aphides which so generally infest the plant. These pretty little spotted insects seem, like the robin, to bear a charmed life, for although children will sport with, they hardly ever harm them; and in France lady-birds are looked upon as sacred to the Virgin, and have gained from this fact the name of "Our Lady's Sheep"—indeed, the French peasants are so careful of them that they will stoop to put them aside rather than run the risk of trampling on them. During the summer of 1868, when the Hop plants were terribly blighted, a most wonderful swarm of lady-birds suddenly appeared in the fields and surrounding districts; so numerous were they in parts of Kent that they could be swept up by thousands. Thus we see throughout creation wherever an evil exists Nature provides the remedy, and through every stage of life one creature lives by the destruction of another.

The study of Nature in all her aspects is of absorbing interest, and the universal charm of rural life and scenes is delightfully touched upon by Cowper:—

"'Tis born with all. The love of Nature's works  
Is an ingredient in the compound man,  
Infus'd at the creation of the kind.  
And though the Almighty Maker has throughout  
Discriminated each from each by strokes  
And touches of His hand, with so much art  
Diversified that two were never found  
Twins at all points; yet this obtains in all—  
That all discern a beauty in His works,  
And all can taste them: minds that have been form'd  
And tutor'd, with a relish more exact,  
But none without some relish, none unmov'd."

—T. S. J.

#### OUR BORDER FLOWERS—LIPWORTS.

No collection of herbaceous plants should be without a selection of this most accommodating race of plants. Their noble habit, their attractive appearance, their beautiful and curious-looking flowers are traits in their character that cannot easily be passed by. For many of our choicest border flowers we are indebted to distant lands. Our present subjects are from the Levant, Cashmere, Armenia, Europe, Siberia, and other countries.

These are among the very best plants we have for what is termed half-wild places, if only they can have light and air afforded them. In large borders when established they pro-

duce a grand effect when they have room to develop themselves. A good loam mixed with coarse grit well broken up is a good medium for them to grow in. They should be supplied with water when they need it. The taller-growing kinds require staking to prevent the wind from beating them about, for if left to themselves they soon become unsightly objects. They are readily increased by seed and division after growth has commenced.

*Phlomis gigantea* is one of the strongest growers of the family, and is a fine plant for the third or fourth row in a large border. *P. tuberosa* is another tall-growing kind, under favourable circumstances attaining the height of from 3 to 4 feet. *P. Russelliana* with its wrinkled downy leaves and purple flowers is a very effective border plant. *P. laciniata* should also have a place in our borders. Then there is *P. pungens*, *P. herba venti*, *P. simplex* and others that might be named. Perhaps the one most commonly met with is *Phlomis fruticosa*, or as it is called, Jerusalem Sage, but it belongs to the shrubby department, as does *P. lanata*.—*VERITAS*.

### AUTUMN PRUNING.

YEAR by year the importance of early pruning becomes more and more admitted, and the benefits resulting therefrom more acknowledged when the work is skillfully done; but still in large establishments I believe there is always some pruning left later than it should be, and in many smaller places it is not even thought about till long after it ought to be finished. No one can be more thoroughly convinced than I am that not a tree in the garden or orchard ought to be touched with the knife a day later than Christmas, and yet with all my efforts it has so far always been three weeks at least later than that time before all has been finished. This season at any rate I hope to have all done by the stipulated time, for certainly the fruit will not interfere with us much either by being in the way or taking up time in gathering, and I have already commenced operations.

Do not let my readers be startled and think I am going to cut all the foliage off my trees by shortening all wood back to two or three eyes. I never prune so hard as that even in late autumn if it can be avoided, being convinced from experience, although for a long time I was very stubborn about it, that the most perfect fruit is produced on plants which are allowed to increase in size annually to a reasonable extent. Call it the extension system if you will, although I do not hold with a system which would produce the greatest quantity of timber in our gardens in the shortest possible time. The object is to produce a fair quantity of fruit of the best possible quality. Where quantity alone is considered I do not hesitate to say that standard trees produce in a given number of years the most when allowed to grow without any pruning whatever, and there are varieties in each class of fruits which from their habit of bearing only moderate crops would also produce fruit of good quality if untouched with the knife; but as a rule the best quality and the most regular cropping is to be found in well-managed gardens or orchards attached to them where the trees are moderately pruned. Mind, I say moderately, for I believe there is more harm than good done by pruning in the present day, hence the outcry in some quarters against pruning altogether; but if sheep-shearing were done by unskilful men who took some of the skin as well as the wool off the animal's back, it would not prove conclusively it was wrong practice to shear sheep.

Nothing is commoner to hear than that an orchard which is left to grow its own way fruits every other year. The reason is that the trees generally fruit too freely when they do bear, and exhaust themselves, while at the same time the fruit produced is comparatively small and only of medium quality. In well-managed gardens, on the other hand, we do not recognise such an event as a fruitful season or an unfruitful one—I mean such results do not recur regularly; of course, if we have the weather in May which properly belonged to January nothing short of ample protection will insure us a crop of fruit. The fruit buds were there this season, bad as the preceding summer was, and a sufficient number of the flowers were perfect, and could have been saved by protection, as was proved by the abundant crop of Peaches saved only by broad coping-boards and a complete covering of frigid domo almost every night from the beginning of March to the beginning of June. I will not say that it pays to grow even Peaches in this way, but as long as I am expected to grow the trees on the open walls I shall endeavour to have fruit on them. But to the pruning.

Such trees as are liable to bleed or emit gum suffer the most from late pruning. Figs, Peaches, and Plums should all be finished so soon as there is no more chance of ripening, say by the end of November, and thinning as far as possible to admit light to the permanent branches without taking off too much foliage should be commenced on all fruit trees as soon after midsummer as the pressure of other work will allow. Do not be afraid to cut into the old wood to remove naked branches or weak unfruitful spurs. Wounds never heal so well or so quickly as when the tree is full of healthy partly matured foliage.

Black Currants have had all the pruning that will be necessary for them—that is, all the weak and as much of the old wood as can be spared has been cut clean away. Raspberries are having all the canes which have done duty this season cut clean out and the young canes thinned to about half a dozen; shortening of these will be deferred till growth has nearly ceased. Pear trees on walls are having all weak spurs cut close off, and the green growth of the remaining shoots pinched a second time. Standard trees of all sorts will have branches cut out where they are too thick or cross each other, and the smaller trees will have the weak useless growth removed so as to admit light and air to that which is intended to remain, thereby lessening the work for November, for unfortunately that is not only the month for pruning, but also for planting and clearing away leaves.—*WM. TAYLOR*.

### FLOWERS WITHIN OUR DWELLINGS.

FLOWERS in the humblest apartments have a delightful effect. Even luxuriously appointed saloons are rendered more enjoyable, and their elegance is increased by a judicious introduction of flowers and foliage. The odour of the flowers, the dark green leaves of some species, and the beautiful tints and varied forms of others, are singularly gratifying and refreshing. Plants of the commonest kinds offer lines of beauty which the eye delights in following and loves to rest upon. So we must have flowers upon our tables if they are ever so common; even a handful of Daisies, Buttercups, or a bunch of Clover, or a few tesselled spikes of feathery Grasses. Have a nosegay if you can morning, noon, and night, for flowers in the morning are especially suitable, they look like the happy waking of creation; in fact, they are always in season, and to arrange them artistically is an elegant attainment. The growing taste for cut flowers for indoor decorations, with nosegays and bouquets as floral ornaments, adds greatly to the charm of both public and private assemblies, for there is no ornament to equal well-arranged flowers.

A growing taste for plants and flowers is doing much for the community both in town and country. Most of the principal towns now have their flower marts, and the flower markets are well stocked with the choicest specimens. The principal one, Covent Garden, is a glorious sight of a spring morning—vanloads coming in from the country, and vanloads going out to furnish the dwellings of the metropolis. Of these flowers so tastefully spread many are tempted to take home a plant or a bunch of flowers, and so the taste for flowers spreads, and spreading, benefits. There is something so alluring in the way in which those floral gems are arranged that they become refreshing objects of admiration, and one of the most pleasing features in the "taste of the times" is the increasing desire for "flowers within our dwellings."—*N. COLE*.

### NOTES OF A SCOTTISH TOUR.—No. 2.

CASTLE KENNEDY—LOUGH INCH CASTLE, THE SEAT OF THE EARL OF STAIR, WIGTONSHIRE.

It is necessary to place these two names together for this reason—Castle Kennedy is so much better known by name, yet it is in ruins and has been so for many years; while Lough Inch is the modern residence, separated from Castle Kennedy by the pinetum, and deriving its name from the lough which lies at the foot of the hill on which it is built. Everyone has heard of Castle Kennedy and its able and intelligent gardener Mr. Archibald Fowler, but few know of Lough Inch, the very fine baronial residence of the Earl of Stair.

Castle Kennedy, like many of the estates of other families, came to the Dalrymples by marriage. It was formerly in the possession of the Kennedys, whose stronghold was on an island in the other lake (called the White Loch) in the demesne, and, like many of the heads of families in those semi-civilised times, were a terror to their neighbours and defiers of the laws. At

last a sort of compromise was made, the stronghold was given up, and the Kennedy of that day engaged to be on his good behaviour. The fort was levelled to the ground, but in a little while a far stronger hold was erected on the mainland. Before, however, it could materially interfere with its neighbours more peaceable times arrived, and a massive ruin alone testifies to a strength long since departed.

The family of Dalrymple has made for itself a name, not merely as the possessor of broad acres, but as having been borne by men of eminence in various walks of life. James Dalrymple, the first Viscount Stair, was a man of philosophic mind, and his work, "The Institutions of the Law of Scotland," remains to this day the guide of Scottish lawyers. John Dalrymple, the second Earl of Stair, was born in 1673, was a companion of Marlborough, and held high command at

the great battles of Oudenarde, Malplaquet, and Ramillies. He was afterwards sent on a diplomatic mission to France, which he conducted with success and in a style of great magnificence. It was of him, I think, that Louis XIV. said he was the truest gentleman he had ever seen; for once on their setting out together the king motioned to him to enter the carriage first. This he did at once; one who was not a true gentleman, the king remarked, would have held back. But he has more claim on our notice from his having been a good horticulturist, and during twenty-two years devoted himself at Newliston to the pursuit of gardening and its sister agriculture. He is said to have planted groups of trees to represent the positions of the British troops at the victories in which he had been engaged, and he was the first to plant Cabbages and Turnips in the open fields in Scotland. Another

Fig. 15.—CASTLE KENNEDY—LOUGH INCH CASTLE.

man of note was Sir David Dalrymple, Lord Hales, who was the author of several works on jurisprudence and also of several volumes of poems; while yet another able member of the family was Alexander Dalrymple the hydrographer, who was much engaged in the Eastern Archipelago, and whose charts were for a long time of much authority. The present Earl seems to have inherited the gardening tastes and business habits of some of his ancestors, and as the property has greatly increased he has been enabled to do much.

In order to understand the position of the place and its general character it is necessary to say that the two places of Castle Kennedy and Lough Inch, although in one demesne, are essentially distinct in character, and have wisely been kept so. Castle Kennedy has for its surroundings a walled garden, which, however, is very much in the way of the view, and will, it is most probable, be ere long removed; while another garden lower down in the grounds and quite out of sight serves the purpose of supplying the family with its requirements in fruit and vegetables. All around this are to be found trees of considerable size, and an immense series of grass terraces, of which fourteen miles in length have to be kept in order. The ruined Castle is situated on an eminence between the two lochs; and at the bottom of it, and in the hollow between it and the other eminence on which the pinetum is mainly placed, is a smaller piece of water, a sort of American valley for *Rhododendrons*, *Azaleas*, *Kalmias*, &c. With regard to the more modern part it is to be remembered that thirty-five years ago,

when Mr. Fowler undertook the duties of gardener, there was nothing but a barren waste; so that Lord Stair and he, working hand in hand, have had the pleasure of seeing the place growing under their fostering care. It already is one of the most interesting places I have ever seen, and in another generation will be something for our grandchildren to see and talk of. Between the pinetum and the Castle there is a piece of waste ground, or rather undressed ground, which will probably some of these days be altered, while at the side of the Castle is the very beautiful parterre arranged in the present style of gardening, represented in the engraving. From the Castle a fine view is had of the White Loch, with its heronry on the island, the pinetum, the old ruins of Castle Kennedy, while Lough Inch lies beneath—the whole encompassed by a line of mountains, low indeed for Scotland, and not of the "stern and wild" character which is said by Scott to mark Caledonia, but carefully planted in some places, in others affording cover for the grouse and blackcock.

It was on the morning of a lovely July day, the very perfection of a day for seeing mountain scenery—a fresh breeze blowing, and fleecy clouds casting their shadows on the mountains, that Mr. Fowler kindly met us in his "machine," the name always given to a carriage here, and drove us round the park, thus giving us a general view of the place. We entered by a neat and unpretending gate and passed some good clumps of Conifers, &c., carefully placed, while cottages belonging to the gamekeepers, &c., are studded about,

Lord Stair not rejoicing in seeing a waste, but preferring to see well-built and solid cottages peeping out from amongst the foliage in various parts of the demesne. We then skirted the shores of Lough Inch, gaining fine views of the mansion at every turn, the long line of grass terraces, the banks of splendid Rhododendrons mingled with huge trees of Fuchsias, which now that the former were over were glowing with their rich scarlet flowers. We caught of course occasional glimpses of the old ruins of Castle Kennedy; and having noted many matters of interest in the details of the planting, of which more anon, we were met at the end of the loch by a lad who took the "machine," and we set out on our journey on foot to view in detail the subjects of interest which had made our drive so agreeable, and with Mr. Fowler as our guide it could not fail to be one of instruction and profit; but as I have personally a strong objection to long papers and imagine that others have also, I must reserve these details for another week's Journal.—D., *Deal*.

#### MR. RIVERS'S NURSERIES, SAWBRIDGEWORTH.

As a grower of fruit trees and a raiser of new kinds of fruit, as the author of works pertaining to fruit-cultivation, and as popularising, so to speak, the subject of fruit-production, as fostering a taste for that pursuit in which he has long delighted to indulge, and promoting the spread of a work both profitable and enjoyable, Mr. Rivers's name is held in esteem by those of kindred tastes in this and other countries, and his nurseries at Sawbridgeworth have become of world-wide fame. They cannot be visited in the fruit season without affording instruction by conveying useful hints and practical lessons. These nurseries are essentially practical. There is no outward display, not even the name of "T. Rivers & Son, Nurserymen," being inscribed at the entrance. Even the fruit trees and orchard houses are as much as possible hidden by a fringe of Conifers; and the visitor, being a stranger, might pass by one of the most famous of English nurseries without supposing that any such establishment existed in the vicinity which he was traversing.

Harlow, on the Great Eastern Railway, is the most convenient station from London for visiting these nurseries. The district is a pleasant one. The roads are flanked by hedges almost of tree-like magnitude, and the undulated pasture lands and corn fields proclaim the neighbourhood decidedly agricultural. The district is well wooded, and the trees, like the hedges, are large and luxuriant, and speak in unmistakeable terms of a fertile and generous soil. To this good soil—good for fruit as well as for forest trees—Mr. Rivers is primarily indebted for his position, but then it required skill to turn it to account so fully and successfully as has here been accomplished.

This has been a nursery for 150 years, and consists now of about as many acres, and continues to increase in size yearly. The greater part of it is freehold, and nearly all is occupied with fruit trees, and contiguous fields have been "taken" and devoted to the same style of cropping to meet the great and ever-growing demands for the commodities of this great pomological farm.

The site of the nursery is boldly undulated, is in fact a series of hills and valleys, and far almost as the eye can reach are "trees, trees everywhere"—trees of almost all kinds and shapes, but not quite of all sizes, for it is remarkable to note that excepting a plantation of Plums and another of Pears for growing fruit for market purposes the stock is all young, and that it is self-evident that great as are the numbers of trees that are raised yearly they are sold off, and that others still younger reign their short reign in their stead. There are trained trees, pyramids, bushes, and cordons, but all young and portable. Trees in pots there are by thousands, Peaches, Nectarines, Plums, Pears, Cherries, and Apricots, and yet this is only one of many great fruit-tree establishments, and the fact is suggestive of the magnitude of English fruit-tree culture.

It is not, however, the increase of old standard kinds of fruit that has made Sawbridgeworth famous so much as the raising and distribution of new varieties, the sterling qualities of which are not only widely recognised in this country, but equally so on the continent of Europe and in America. In the raising of new fruits Mr. Rivers was ahead of his fellows in appreciating the importance of one point—earliness, and to that supreme point he has directed his attention. To be "first in the market" is the desideratum of all mercantile men, and especially to be "first" with fruits is an advantage of the

greatest moment. A week, or even half a week, in advance is a most fortunate position to secure, for in that or less than that time fruit will depreciate in value quite 50 per cent. A striking instance of this is afforded by Early Rivers or Rivers' Early Prolific Plum. This Plum realises double and treble the price of other Plums, principally on account of its earliness combined with its superior quality. Of this Plum eight hundred bushels were sent to market from Sawbridgeworth last year, and commanded more than double the price of other Plums then offered in Covent Garden. Similarly is the advantage of earliness demonstrated with Peaches—a fact which the English have not been quite so wide awake to as our continental neighbours and American friends. They provided themselves largely with these advanced varieties as soon as their character was proved, and now the French and Belgians are "first" in the English market with foreign-grown fruit of English-raised seedlings. In some parts of America where Peach culture is carried on on a scale of great magnitude the value of the Sawbridgeworth seedlings is being freely recognised, and large numbers of such sorts as Early Beatrice and Early Louise have to be provided to meet the great export demand, for these sorts are assuredly "first in the market" wherever they are grown. They supersede Early Rivers, for the latter is prone to crack at the stone—a warning which its raiser can afford to honestly aver in his catalogue. On a small scale as well as on a large one the importance of gaining a week in delicious and perishable fruit is a matter of great consequence, and hence no garden is considered complete which does not contain the earliest as well as the best of everything in season.

But fruit trees are not only grown on a scale of great magnitude in the open air, but they are also cultivated under glass in greater numbers than are to be found in any other establishment. The quantity of fruit produced in the orchard houses at Sawbridgeworth is enormous, and is unquestionably a source of great profit to the owners. The structures devoted to fruit-growing are both numerous and extensive. There are thirty-five houses—not, like many of the trees, "miniatures," but several are 100 feet in length by 24 feet in width, span-roofs; and lean-tos range from that up to nearly 300 feet in length. It is not necessary to notice each house separately, for their contents are constantly being changed to advance or retard the different crops, and in otherwise carrying out the routine of the establishment. These houses, as is generally well known, were not built to "look at." They are home-made structures, erected in the first instance as experimental, but have long since proved their worth and value in a manner quite indisputable; and that they are not fragile their long years of service and their present substantial state is sufficient testimony; and that they also answer their purpose as well as more elaborate and costly-built houses the fruit which they have produced, and which they now contain, affords substantial evidence. Many of these houses are heated and many are unheated. Their sides, where there are sides, are formed of boards supported by oak posts, some of the posts being encased in iron sockets, and other houses have brick foundations; but all have been erected on principles of economy and usefulness, and as proving how large and certain crops of fruit may be produced at the least cost. Mr. Rivers has not indulged in the "luxury of building," but his object has been fruit-growing, and he has succeeded.

The trees are grown in pots with but a few exceptions. Let us take as a sample of many others one of the large span-roofed houses. There are two rows of trees along the centre. These trees are 10 to 12 feet high, and are furnished almost down to the pots with foliage, and are laden with fruit. There are two other rows of trees along each side of the house, trees of lower stature but also heavily cropped. Some of these trees have been cultivated in pots for upwards of twenty years and have branches gaunt and scraggy, but the foliage is as healthy as ever, and the growth is as free and the fruit as good as on younger trees. The soil is removed from the pots to two-thirds of their depth annually, and the fresh soil is supplemented by rich top-dressings, and this practice with freedom from insects preserves the trees in their healthy fruitful state. But a few trees are planted out, standards, and are wonderful by their mode of growth and productiveness. Their stems are about 6 feet in height and 6 inches in diameter, and their heads are 6 to 8 feet in diameter. The trees were planted in the ordinary soil many years ago, and it is as healthy as ever, dressed, or watered. The surface is almost as dry as dust, yet the trees are in perfect health.

crop of Peaches is most abundant, the trees requiring no "pulleys" to "bring down" the branches. Trees of Royal George, Noblesse, and other sorts produce ten to twelve dozens of Peaches annually of first size and quality. The roots of these trees have evidently penetrated to the soil outside the house, and the soil inside receives some water which passes through the soil of the trees in pots, but beyond this the roots are not watered. There can be no doubt whatever that this house produces many more Peaches and Nectarines than could be produced were the house trellised and every part covered with fruitful branches. The fruit on these planted-out trees hangs almost in clusters, and the trees require only the smallest possible amount of attention. Neither training nor pinching is resorted to; all that they require and receive is one severe pruning annually, and that in winter. In consequence of this close pruning the terminal shoots are strong and luxuriant, and cause a free flow of sap to the fruit which is produced by the twiglets. The term "twiglets" is used in contradistinction to spurs, for the small internal growths of the trees are not pinched but are left to mature to their full length of 6 to 9 inches. It is found that more air is permitted to circulate in the interior of the trees by this system than is the case by the pinching; labour is also saved, and profitable crops of fruit are produced. It is the simplest of all modes of Peach-growing—is, in fact, a counterpart of Apple-growing in well-kept orchards. Besides Peaches and Nectarines, Apricots are largely cultivated in pots, and heavy crops of superior fruit have been gathered, the remnant of the harvest being now in course of ripening. Mulberries are also grown, the fruit being now ripe and greatly superior in size and quality to fruit which is produced in the open air. A good-sized bush produces many dishes of fruit. Other houses the same size as the one described are similarly occupied with a few modifications, such as having more trees planted out or the houses being partially trellised, for trees are grown under all forms of treatment and systems of training.

Another old house is noteworthy as showing how every place is turned to account in this nursery. It had been a vinery for thirty years, and is now a trellised Peach house. The Vines were removed and standard Peach trees were planted in the outside borders, bringing their heads inside the house, and without any more border preparation excellent crops of Early Beatrice, Early Louise, and other sorts are now being gathered. Thus a plain structure which cost a mere trifle in its erection more than a quarter of a century ago cannot fail to be highly remunerative for several years to come. Another old house near it is still devoted to Vines, which bear heavily. For a number of years they were pruned on the spur system and eventually failed, when young rods were trained up, and the house is again filled with Grapes. Under the Vines Figs are grown on bushes, and good crops are produced.

Here may well be noted a few of the best kinds of Peaches and Nectarines. The earliest Peach is undoubtedly Early Beatrice. The fruit is somewhat small, but is of excellent quality. It was raised from the white Nectarine. Closely following it is Early Louise, a larger and darker fruit, melting, juicy, and excellent; a most valuable Peach, raised from Early Albert. The next in order of ripening is Hale's Early, a fine American kind above medium size, handsome and excellent. Then comes Condor, a large, fine, and good Peach. Ripening about the same time is Rivers' Early York, a medium-sized delicious Peach, superior to its parent Early York in not being liable to mildew. This is followed by Dr. Hogg, a full-sized dark, handsome fruit of excellent quality, the tree being a vigorous grower and productive. A fine Peach to follow is Princess of Wales, very large, handsome, and superior; and still later are the two fine kinds, the Nectarine Peach and Alexandra Noblesse, two of the finest Peaches in cultivation, but not always ripening in the open air in cold seasons and districts. The kinds named will with orchard-house culture provide a supply of fruit of the first quality over a period of at least five months. In the nursery are many unnamed seedlings, one of which, a most productive kind, has the quality of Grosse Mignonne, the size and shape of Bellegarde, and the colour of Noblesse; a distinct and valuable Peach, worthy of a good name.

The best Nectarines arranged as nearly as possible in the order of ripening are the following:—Advance—this is a new early Nectarine, ripening a fortnight before Lord Napier, and on that account is specially valuable. The fruit is, perhaps, rather small, but possesses a rich Stanwick flavour. Next comes Lord Napier, one of the most important Nectarines

which has ever been offered to the public. It is early, hardy, productive, large, and of excellent quality. It was raised from the Early Albert Peach. This is followed by Rivers' Orange, a large melting Nectarine of first quality, a week earlier than its parent Pitmaston Orange. Stanwick Elruge comes next, a large rich fruit, possessing the peculiar flavour of the Stanwick, and is earlier than its parent the Elruge. A fine Nectarine following is Humboldt. This is very large, rich, and productive; it was raised from Pine Apple, and is almost or quite equal in flavour to that fine kind which comes next on the list. Pine Apple is a prince among Nectarines. Fruits of it have this year ripened in the orchard house 9 inches in circumference. The colour is orange and crimson, and in quality it is extremely rich. In ripening it is a week or so later than Pitmaston Orange. The last to notice is the late kind, Victoria. This requires a warm climate or the aid of glass to ripen perfectly, it is then very large and excellent. The few kinds named are selected as affording a long succession of fruit of the best quality. If only one tree can be grown choose Lord Napier; if two, add Pine Apple. These are two of the best Nectarines at present in cultivation, and will be standard kinds for a long time to come.

We pass to the Cherry house. Than Cherries no fruit is more worthy of the protection of glass, and none more certainly and profitably cultivated. Indeed it is seldom that the Cherry can be perfectly ripened in the open air—birds, wasps, &c., preventing the fruit from hanging sufficiently long to bring out its full qualities. Many kinds of Cherries require to hang almost to the shrivelling point before they can be perfected, and this can only be the case when trees are grown under glass. The size and colour of the fruit is also as much superior as is its quality over fruit that is produced in the open air. Of this convincing proof is afforded by the fruit at the great exhibitions, the prizes invariably being secured by gardeners who grow their fruit under glass. The Cherry house at Sawbridgeworth is a span-roofed structure, light and well ventilated. The trees are grown in pots, and they have been heavily laden with splendid fruit. Some fruit still remains, and in its partially shrivelled state is most delicious. Some of the best sorts for cultivation in pots are Early Rivers, a seedling from Early Purple Gean, early, hardy, and rich; Empress Eugénie, the earliest and the best of the May Duke type; Bedford Prolific, similar to the Black Tartarian; Bigarreau de Schmidt, very large and rich; Governor Wood, a valuable light red American kind; Monstruense de Mezel, a monstrous red fruit of excellent quality; and Florence, a very large Cherry with a firm crackling flesh, and which hangs a long time after it has ripened. The above Cherries will provide a supply of superior fruit over a long period of time, and are highly worthy of being grown under glass.

Vines are grown in enormous numbers, house after house being devoted to them. There are probably five thousand in pots, hundreds of them—early fruiting canes—being grown on the hot-water pipes, so that there can be no rooting through the pots. All the best kinds in cultivation are cultivated in numbers proportionate to the demand for each. The most popular by far are the Black Hamburgh and Muscat of Alexandria. That fine Grape Madresfield Court is also in great request; so also amongst the later are Alicante, and especially Lady Downe's Seedling. There are moderate numbers of Mrs. Pince's Black Muscat, Gros Colman, and other sorts. Amongst white Grapes Foster's White Seedling and Buckland Sweetwater are the most popular. The Frontignans are also in great demand; and for early Grapes of superior quality few can surpass such sorts as the Early Smyrna, Primavis, and Tokay Frontignans. For exhibition purposes they are unsuitable, but for table quality they are unsurpassable. Mr. Pearson's and Mr. Thomson's Grapes are also grown freely—Dr. Hogg, Golden Queen, and Mrs. Pearson of the former raiser, and Golden Champion and Duke of Buccleuch of the latter. Very many kinds are planted out and fruiting, and amongst these the Duke of Buccleuch. The berries are very large and sweet, and are remarkably thin-skinned. Ryton Muscat as grown here is evidently a superior Grape. In quality it is similar to Muscat of Alexandria, but the berries set better and the Vine is more hardy. Orange trees are largely grown, and are sold as fast as they arrive at a fruitful size. The plants are consequently small, but were bearing fruit of excellent quality.

In the outside quarters the trees of all kinds of fruit in pots are remarkable for their numbers, health, and cleanliness.

Scarcely an insect or a speck of mildew was to be seen. Pure cold spring water is the only cleansing medium resorted to, and with this the trees are syringed freely. The plantations of miniature bush and pyramid Pears, Apples, and Plums are many of them bearing freely. Noticeable amongst the latter was The Czar, a new, fine, dark, and most productive Plum, ripening immediately after Early Rivers. These with Oullin's Golden Gage and Prince Englebert are considered to be amongst the profitable Plums at Sawbridgeworth, and are largely planted for market purposes—that is, for producing fruit for sale. Some of the most profitable Apples for dwarf trees are Cox's Orange Pippin, Lord Suffield, Duchess of Oldenburg, Stirling Castle, and Ecklinville Seedling.

The espalier orchard is also noteworthy. The trees are trained in various forms to wire trellises 6 feet in height, the trellises being about 4 feet in diameter. These are so arranged that they can be covered with glass if needed. Undoubtedly a great quantity of fruit can be quickly obtained off a given piece of ground by this mode of culture, and the trees can be conveniently protected from spring frosts.

Roses are grown by the acre of all the standard varieties, and there are good collections of Conifers. Flowers are only sparsely represented. Yuccas grow most vigorously in clay, and there is a large plantation of Chinese Peonies. On the lawn are good Wellingtonias and standard Nuts, which are ornamental and productive. One of the best Nuts is the Atlas Cob (*Corylus algeriensis*), the clusters being of immense size and produced in great profusion.

The heating of the various houses is mostly done by small boilers, one being placed outside each house, and can be moved when necessary by sacrificing a couple of indiarubber rings, and be placed where required and connected with the piping inside. These are coil boilers such as are manufactured by Mr. Read and Mr. Deard, and it is astonishing to see how powerful they are—one apparatus of four 1½-inch coils, forming a cylinder 8 inches in diameter, being sufficient to heat 250 feet of 3-inch pipes. Mr. Rivers's foreman spoke most highly of these boilers, of their economy and efficiency.

To Mr. Rivers, jun., and his competent foreman, Mr. Elsdon, I am indebted for much courtesy and attention—A VISITOR.

### ROTATION OF CROPS.

WE know it to be true, as "A CORRESPONDENT" states, that Potatoes have been grown on the same plot for several successive years, but there was always a crop of Cabbageworts intervened and manured for. The manure, we think, was not the only source of nourishment to the Potatoes, but these also derived nourishment from matters given out by the roots of the Cabbages. We have always found that Potatoes do well after them, and that the roots of Cabbages and all the Brassica tribe give out peculiar excretes to the soil we have often noticed. Mr. Cuthbert Johnson has in the "Journal of the Bath and West of England Society" the following notes on "the excreta from roots":—"In reply to my inquiries, Mr. Purser remarks:—

"I have much pleasure in answering your inquiries as to the continued success of mixing the Turnip with both the Mangold and the Kohl Rabi.

"We have tried it now for some years, and have been most successful, having escaped the loss of plant from graping, or, as the disease is better known, from branching out into fingers and toes, and the Turnip rotting away altogether. This season has been a very trying one, as we have scarcely had a shower for many weeks, and the Turnips are the best sown with the Kohl Rabi this year, having been a month later sown than with the Mangolds, but both have escaped disease, and the later ones are now bulbing well.

"The Turnips have been grown upon the same ground with both Mangold and Kohl Rabi, and grow well still, and to a great weight. The quality this year with Mangolds, owing to the fearful drought, will not be so good, but free from disease."

"The conclusions at which we may reasonably arrive, then, are that plants probably excrete matters into the soil that are nutritious to certain plants of a different kind to themselves, and that these excreted matters are but very imperfectly known to us."

### FRUIT FARMING.

AT a meeting of members of the Midland Farmers' Club, held in Birmingham, the Rev. W. Lea read a paper on "Fruit Farming." He said the chief point to bring forward for dis-

cussion was, "Will it pay a farmer in the present day to make the growth of fruit a portion of the regular work of his farm?"

A few years ago he should have answered without any hesitation in the affirmative; but before he did so now he should first inquire into the condition of the labour market in the district in which it was proposed to plant. Fruit was an article which must go off when it was ripe; if it was not gathered and marketed some sorts would be spoiled, and to gather it a certain amount of women's and children's labour was required. If this was at command one difficulty would be removed. The question of soil and situation should, of course, be considered. There were few soils, even the lightest sands, which would not bear some variety of fruit. But before a man began to plant he should ascertain from a careful inspection and inquiry in the neighbourhood what fruits were congenial to the soil, and confine himself, of course, to those sorts. There was no certain rule to be laid down on the subject. Some districts were most suitable for the Apple, others for the Pear, others for different kinds of Plums or Damsons; and sometimes in one field the soil varied so much as to make it desirable to plant one variety of fruit at one end of it and a different one at the other.

Next came the question whether the landlord or the tenant should plant; if the latter, would it pay him to plant on a seven, fourteen, or on a twenty-one-years lease? and if he left at the end of these terms, what compensation should he receive, and from whom should he receive it—from the landlord or from the incoming tenant? He was of opinion that the best arrangement would be for the tenant to plant, and for the landlord to undertake to pay at the end of the lease the cost price of all trees left in healthy condition, and interest upon the outlay at 5 per cent. per annum. Fruit planting was profitable both to landlord and tenant if properly done and the sorts well selected.

The advisableness of planting young fruit trees in a hedge-row must depend a good deal on the age and strength and nature of the hedge. If it was of old, vigorous Quick, the roots would probably have taken such an entire possession of the soil that a stock newly introduced into it would only lead a sort of languishing existence for several years; perhaps, and then die away. But if anyone wished to try the experiment, he should recommend him to plant wild stocks, and graft them with the sorts desired. If a hedge were being planted there would be no such difficulty; the fruit trees would have the same chance as the Quick, and both would grow up side by side together. This plan would be worth trying, or, indeed, the first-mentioned, provided the hedge was between two arable fields. If it were between two grass fields, or with a grass field even on one side, the advantage would be questionable; for the cattle, in trying to get at the fruit—of which they are very fond—would probably do as much harm in breaking the fences as would be covered by the profit of the fruit. Some damage, too, would unavoidably be done to the hedge in the gathering of the fruit.

Planting an orchard on turf was comparatively expensive, which was a point requiring to be taken into account. A good deal of labour was required to do it well, and if it was not done well it was better not attempted at all. On the whole it was questionable whether it would pay to plant an orchard on turf, except on some banky sloping fields with a south aspect, which seemed specially adapted to the purpose. Then came the third alternative, which seemed to him the most desirable—to plant an orchard on a well-fenced piece of arable, as near as may be to the house, and from which cattle of all kinds are to be entirely excluded. Here it might be done at much less expense, as no protection would be required except against ground game. Supposing an acre to be square it might be cultivated in two ways—(1), by planting standard fruit trees in rows 30 feet apart, and by filling up the space between with rows of Plums and bushes; (2), by standards—Apples, Pears, and Cherries, by Plums or Damsons, by bushes, Currants either Black or Red, and Gooseberries. According to this plan the whole field would have to be cultivated with the spade, and would take pretty well the whole time of one man if it were three or four acres in extent.

What was called "pot fruit" was required now as a rule. The Apples and Pears which paid best were those which came in earliest and which kept latest. These last probably brought the highest price. But when the cost of storage and of picking over had been deducted, he doubted if they paid so well as the first. If they were going to buy trees, let them go to the nurseries themselves, select and mark the trees to be sent in

planting season. They were not necessarily to pick out the biggest, but rather vigorous, healthy, young stocks, which showed no sign of having been checked or stunted in their growth. They should not go in for too many varieties of fruit. On his three acres he had more than one hundred sorts of Pears, forty of Apples, thirty of Plums, to say nothing of Currants and Gooseberries. From his own point of view this variety was necessary; for he was experimenting to see what sorts would best suit the locality and pay the best; but to farmers this endless variety would be very troublesome, especially if the specimens were dotted about in different parts. The best plan, if they were planting a hedgerow, was to plant it all with one sort of fruit. Then, one going over the ground, or at most two gatherings sufficed, and a vast deal of labour and confusion were saved. So, too, in orchards, whether on turf or arable. If they had several sorts let them keep each sort in a separate row; or if more than one row of the same sort was desired they should have the rows together, so that that portion of the ground might be cleared at once of its produce. They should be very careful about the pruning for the first three or four years until the heads were got into shape. After this the trees might be left to themselves, merely cutting out the branches which interlaced from time to time.

### NOTES AND GLEANINGS.

We omitted to notice that at the last meeting of the Floral Committee at South Kensington twelve varieties of cut blooms of DOUBLE PELARGONIUMS were exhibited by Mr. Cannell, Swanley, Kent. The varieties were *Jacobæa* (Laxton), *Lucie Lemoine* (Lemoine), *Eugène Bandowin* (Keteleer), *Henri Beurrier* (Alegatiere), *Konig Albert*, Ivy-leaved (Liebman), *C. H. Wagner* (Alegatiere), *Figaro* (Lemoine), *Louis Boutard* (Boutard), *Louis Buchner* (Buchner), *M. Buchner* (Lemoine), *Mdme. Amelio Baltet* (Lemoine), and *Meteor Flag* (Turner). This was the finest collection of double Pelargoniums that has come under our notice. The colours varied from pure white to rich crimson. A vote of thanks was awarded for them.

— NEVER CUT FLOWERS during intense sunshine, nor keep them exposed to the sun or wind. Neither collect them in large bundles, nor tie them tightly together, as it hastens their decay. Do not pull them, but cut them cleanly off the stems with a sharp knife, not with a pair of scissors. When taken indoors place them in the shade, and reduce them to the required length of stalk with a sharp knife, by which means the tubes through which they draw up the water will be left open, and the water will ascend freely; whereas if the stems are bruised or lacerated, these pores will be closed up. Use pure water to set them in, or pure white sand in a state of saturation, sticking the ends of the stalks in it, but not in a crowded manner. If the stems are put in water alone it ought to be changed daily, and a thin slice should be cut off the ends of the stalks at every change of water.

— ONE of the most brilliant of hardy border plants is the DOUBLE SCARLET LYCHNIS. We lately saw plants flowering in the collection of Mr. Ware of Tottenham, and the remnants of the flowers which had been left by the hailstorm were quite dazzling. The individual pips are as large as those of double Pelargoniums, and the colour is brighter than the brightest of the Pelargoniums. For distinct effect few plants are more conspicuous than this double Lychnis, and the flowers also will bear the closest examination. As a companion plant the double white Lychnis is also worthy of culture. The plants are perfectly hardy, will flourish in almost any kind of soil, and require little attention beyond thinning-out the shoots and staking to prevent them being broken by the wind.

— THE double-flowered Ivy-leaved PELARGONIUM KONIG ALBERT is likely to prove the forerunner of other valuable varieties of the same type. Already Mr. Bull of Chelsea has raised some seedlings, which are perfectly double and varied in colour, and which can hardly fail to be sought after. Unlike the doubles of the Zonal type, the new Ivy-leaved varieties possess the same free-flowering habit as the single varieties; and as the colours are pleasing and distinct from those of the Zonals, and the trusses have long and stout footstalks, they will be valuable for bouquets and other purposes to which cut flowers are devoted.

— IN another column it is noted that a subscription list is organised for the relief of the sufferers by the late HAILSTORMS which recently devastated the districts in the north and north-east of London. We have lately passed through those districts,

and seen how extreme is the injury which has been done to nurseries, gardens, and glass structures. In some places scarcely a vestige of foliage is left on the crops and plants. More than 90 per cent. of the glass has been broken in green-houses which were exposed to the violence of the storm, and we can testify that the losses are fully as great as have been represented.

— THE number of persons who visited the Royal Horticultural Society's Gardens on Bank Holiday, August 7th, at 2d. each, was 5705 = £47 10s. 10d.

— JUST on the eve of going to press we have received a box of blooms of single Petunias from Mr. Cannell, Swanley, Kent, which for size, richness of colour, and purity of markings, surpass all that have previously come under our notice.

— ARUNDO DONAX is growing luxuriantly in the nurseries at Sawbridgeworth, and its stems are turned to profitable account as supports for the training of fruit trees and other useful purposes. It is perfectly hardy, requiring no protection whatever during the winter or spring. This plant is a native of the south of Europe, growing in moist places, and its canes are employed for fishing-rods and for the training of Vines. Planted by the sides of water in the southern parts of England this fine Reed would have an ornamental effect, and the dried canes could be turned to account in providing straight and neat supports for plants in the flower garden. The young shoots of this plant have been recommended to be eaten as Asparagus.

— OWING to the extreme heat and drought, and the dry gravelly subsoil, many of the LIME TREES in the neighbourhood of London, notably on Clapham Common, are entirely denuded of their foliage, and present quite a cheerless appearance. It is the fashion now to plant Limes somewhat freely as ornamental trees on account of their free growth, but their short period of leafage in dry soils is a matter worthy of being remembered. In strong moist soils they will remain green and fresh for some weeks to come.

— THE pomological display in connection with the PHILADELPHIA INTERNATIONAL EXHIBITION will take place from September 11th to September 16th, in a special annex to the Agricultural Hall. Tables and dishes will be provided free of charge, and the contributions will also be received, unpacked, and labelled by the department. The display will consist of sixteen classes, from Nos. 881 to 896. No. 881, summer Apples; 882, autumn Apples; 883, winter Apples; 884, summer Pears; 885, autumn Pears; 886, winter Pears; 887, freestone Peaches; 888, cling Peaches; 889, Apricots; 890, Nectarines; 891, Plums; 892, native Grapes; 893, foreign Grapes; 894, Water Melons; 895, Citron Melons; 896, tropical plants. Intending exhibitors should apply without delay to the offices of the British executive, 5, Craig's Court, Charing Cross.

### ROSE JOHN BRIGHT.

MR. CAMM, at page 91 of the present volume of the *Journal of Horticulture*, is under a misapprehension in making me the foster parent of H.P. Rose John Bright, which is one of Mr. George Paul's seedlings; I am not, therefore, responsible for the alliance he makes between imperialism and democracy. Empress of India is one of my seedlings, and sent out by Mr. G. Paul. It is a very fine dark show Rose, but I fail to see its likeness to Reynolds Hole. The worthy namesake of that Rose says, "It is a commixture of Pierre Notting and Louis Van Houtte, though quite distinct from both, and seems to me full of promise." The wood of the Empress is spiny, and the petals somewhat overlap in the way of Louis XIV. Her Majesty was raised to the dignity of Empress, and received a first-class certificate from the Royal Horticultural Society long before the mention of the imperial title met with hostility.—THOMAS LAXTON, Stamford.

### CHEAP AND EFFECTIVE ICE HOUSE.

AN ice house made of rails on the top of the ground in the open sun will preserve ice all summer if rain is kept from it, and a foot of sawdust is kept between it and the earth. The ice must be closely packed to prevent a continuous contact with air at every point. My ice house stands in the sun on a dry knoll, is made of rough boards about 12 by 16 feet half-board length, 8 feet high, has a steep board roof, a north window, never shut in summer, with 8 or 12-inch upright studding inside; inside horizontal boarding, and filled between these two boardings with sawdust pounded down. The floor is made

of pieces of rails, boards, &c., laid on the ground and cross-laid, and covered with a foot of sawdust. On this a layer of ice cakes is placed, leaving a foot or more on the outside for sawdust, and sawdust is placed between the cakes that do not fit closely, and the last layer is well covered with the same non-conductor. In summer the sawdust is occasionally packed down, and large ice blocks when wanted sawed into smaller pieces and repacked. This ice house cost me about \$5 labour and \$15 to \$20 for hemlock lumber, \$2 for saved sawdust, \$3 to \$5 a-year for six to ten loads of ice blocks from the lake, and when ice-gathering has failed one or two seasons ice has been found in good condition the second summer. A chunk of it will last half a day in a covered tin pail in dog days; it cools our milk and cream, and, in short, is winter saved for use in summer.—W. W. NEWMAN.—(*New York Tribune*).

## PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

**BONGARDIA RAUWOLFII.** *Nat. ord., Berberidaceæ. Linn., Hexandria Monogynia.*—"Bongardia Rauwolfii has a very wide range in geographical distribution, from the islands of the Greek Archipelago (Chios and Rhodes), through Asia Minor, Syria, and Persia, to Afghanistan and Beluchistan. In Syria and Persia it is said to be found in cornfields and to be used as an acid pot-herb. Plants of it have been received at Kew from Max Leichtlin of Carlsruhe; and from N. Elwes, Esq., the latter of which flowered in the spring of the present year in the open border."—(*Bot. Mag., t. 6244*).

**DUVALIA POLITA.** *Nat. ord., Asclepiadæ. Linn., Pentandria Digynia.*—"This flowered in the Royal Gardens, Kew, in the summer of 1874, and is now coming into flower again. Its history and the precise locality from which it came are unknown, although not uncommonly cultivated by Stapelia growers under the names *Stapelia polita* and *S. echinata*. With the exception of *Duvalia Corderoyi* it is the finest of the genus, and is remarkable on account of its regularly six-angled stems and very shining corolla, the lobes of which are less replicate than those of any other species in the genus."—(*Ibid., t. 6245*).

**EULOPHIA MACROSTACHYA.** *Nat. ord., Orchidaceæ. Linn., Gynandria Monandria.*—"A very graceful Orchid, introduced into the Horticultural Gardens from those of Peradenia by Mr. Watson, their then superintendent, so long ago as 1837, and more recently sent to England by Dr. Thwaites, from whose specimens cultivated at Kew the drawing now reproduced was made in 1860, and who states that it is not uncommon in the central province of the island, ascending to 4000 feet. It is also, according to Wight, a native of the eastern slopes of the Neilgherry Mountains. Lindley describes it as one of the easiest-grown of Orchids, flowering late, and producing fresh flowers till Christmas; ours bloomed first in January, 1864."—(*Ibid., t. 6246*).

**LEUCOTHOE DAVISLE.** *Nat. ord., Ericaceæ. Linn., Octandria Monogynia.*—"This handsome evergreen Ericaceous shrub was discovered in 1853 by Mr. William Lobb on the Sierra Nevada Mountains of California at an elevation of 5000 feet. It was sent by him to Messrs. Veitch, and distributed by them under the name of *Leucothoe Lobbii*. It was gathered again in the same tract by Miss N. J. Davis, after whom it was named by Dr. Torrey, and this name has been adopted by Dr. Asa Gray in the Proceedings of the American Academy, and in the valuable work on the botany of California, of which we have just received the first volume. It is the only species of the genus which has been found on the western side of the American continent. From the two well-known and long-cultivated species of the Eastern States (*L. axillaris* and *Catesbeii*), it differs by its shorter nearly entire much less-pointed leaves, and by having its larger and handsomer flowers aggregated into a panicle at the end of the branches. So that, horticulturally, it is a decidedly finer plant, and of course, coming from such an elevation, it may be safely relied upon as quite hardy."—(*Ibid., t. 6247*).

**AGAVE BOTTERII.** *Nat. ord., Amaryllidaceæ. Linn., Hexandria Monogynia.*—"This plant was sent a long time ago from Mexico by M. Botteri to Mr. Wilson Saunders. When this was dispersed it was purchased by Mr. J. T. Peacock, with whom it flowered at Sudbury House, Hammersmith, in the spring of 1875. It is a *Littæa* as regards inflorescence, and, according to his classification, founded on characters, falls into the group "Subcoriaceæ," which combines the small teeth of the "Aloideæ," with a much thinner leaf, with the firmer texture of the large-spined panicked species of the series

of which *A. americana* and *Scolymus* are best known representatives."—(*Ibid., t. 6248*).

**GAMOLEPIS EURYOPOIDES.** *Nat. ord., Compositæ. Linn., Syngenesia Necessaria.*—"G. euryopoides is a native of the mountains of British Caffraria, Uitenhage, and Albany, at about 2000 feet elevation. It was raised at Kew from seed sent by Mr. Tuck of the Grahamstown Botanic Gardens in 1865, and flowers annually on the Cape shelf of the temperate house."—(*Ibid., t. 6249*).

**APPLE.**—*Peasgood's Nonesuch.*—"This is without doubt one of the handsomest autumn Apples in cultivation, and is besides an Apple of good quality. It was raised by Mr. Peasgood of Stamford, and when exhibited at South Kensington in September, 1872, was awarded a first-class certificate by the Fruit Committee of the Royal Horticultural Society. We take Dr. Hogg's description of it from the 'Fruit Manual,' which runs as follows:—'This is very like a very large Nonesuch, and not unlike the Blenheim Pippin when well grown. It is large, 3½ inches wide and 3 inches high, roundish, somewhat oblate, and very handsome. The skin is yellow, overspread on the sunny side with red, and copiously streaked with bright darker crimson streaks. Eye very large and open, set in a deep, round, and even basin, and with short stunted calyx. Stalk short, deeply inserted. Flesh yellowish, tender, very juicy, with an agreeably acid flavour. A fine culinary and dessert Apple.' This noble-looking Apple has been recently sent out by Messrs. W. & J. Brown of Stamford. Besides the certificate at South Kensington above referred to, it gained a first-class certificate at the Show held at the Crystal Palace in September, 1874."—(*Flor. and Pom., 3 s., ix., 181*).

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### HARDY FRUIT GARDEN.

WALL trees have been looked over, and all the foreright shoots have been cut off to a leaf or two from the base of each shoot. The very dry weather has rather checked their growth; but there is very little fruit upon either Plums or Pears, so the growth has been sufficient. The Pear trees are trained on what gardeners call the horizontal system of training. Each branch is a cordon, and is spurred in closely, none of the side branches being nailed-in to the wall. There is no summer nailing with these trees, and a man accustomed to the work can go over their dressing very rapidly. The shoots are taken between the thumb and the edge of a sharp knife and are broken off. Some gardeners partially sever the shoots and leave them hanging. This is supposed to prevent the eyes from starting, and it does to a certain extent; but the shoots hanging loose are untidy, and there is not much gain from it, as the eyes at the base of the young wood are not likely to become fruit buds.

Plum, Peach, Nectarine, Apricot, and Cherry trees are trained on the fan system, and this requires a certain amount of young wood to be laid-in annually. This has already been done; but many of the shoots are apt to become loosened by the wind, and some of them grow considerably after the first nailing. These must be nailed-in this month, as not only does it make the trees have a more neat appearance, but the fruit becomes more exposed to the ripening agency of the sun and air. Where Peaches and Nectarines are shaded by the leaves these ought either to be removed or laid aside. If the latter cannot be done the leaves ought not to be stripped off, as this would be injurious to the buds at the base; but they may be cut, leaving part of the leaf, which will perform the same function that the whole one would have done.

Fig trees also require a little attention at this time. The fruit is now approaching the ripening stage, and ought to be exposed to the sun to bring out the flavour. We have always seen the best crops of Figs from trees that have been trained very loosely, the shoots being allowed to hang from the wall. This is perhaps objectionable in some gardens, as loosely hanging shoots are always considered a mark of untidiness. If they are nailed closely in to the wall the knife must be used as little as possible, as the shoots that are trained in now will carry a crop next season.

Vines trained to walls must not be neglected. The lateral growths require a final stopping, and the young wood intended to bear fruit next year should also be stopped if it has grown to the prescribed limit. All such young rods should have sufficient space to develop the leaves fully and allow of some lateral growth. All laterals to be stopped at the first leaf. Dust with sulphur to destroy mildew, and syringe to prevent red spider.

The Strawberry plants are now quite free from red spider and mildew, and a little rain having fallen the plants have been put out in the beds, and we shall water them freely if no more falls. A shallow depression is formed around each plant, and the water is applied through a coarse rose. The plants must not be

neglected at this time, as they require to make a good growth before the month of October. By that time the crowns will be formed. All the plants for forcing have been potted, and the pots placed on bricks in a sunny position.

#### VINERIES.

The early Vines are better furnished with leaves this season than they were last year at the same time. The wood is perfectly ripe; but the longer we can keep the leaves in a healthy state the better for the future welfare of the Vines, for while they are healthy they continue to nourish the buds at their base. If the leaves should be removed from the earliest Vines they must be kept as cool as possible. The weather is now somewhat cooler, but it is still unnecessary to apply artificial heat to late vineries. It is well to have the fruit fairly ripe by the end of August, and if it is seen that this will not be the case artificial heat must be applied, and the ventilators should be open a little night and day. If there is any appearance of mildew paint the pipes with flowers of sulphur made into a paint with soapy water. The pipes must be made rather hot afterwards, just sufficient to fill the air with the sulphur fumes. Sulphur is by far the best agent to destroy mildew; but when the fungus has spread over the leaves and fruit very extensively, all the affected parts ought to be touched with the sulphur. But no good gardener would allow his Vines to get into such a state, but on the first appearance of the enemy he would take steps to check its advance.

The trellises of our late vineries are quite covered with the growth of the Vines, and all lateral growths that are made now are removed by pinching them closely. Both outside and inside borders should be watered if necessary. The Grapes will not colour well, nor will they be of good flavour if the Vines suffer for want of water. Ripe Grapes are a prey to wasps and bluebottle flies at this season, and we have tried different ways to protect them from their attacks. Medicated bags or bags of any material are bad; the Grapes are more liable to decay in them, and you require to be constantly taking the bags off to examine the fruit, else you may find some of the best bunches a mass of decay. Beer in bottles wasps do not prefer to ripe Muscats; indeed no syrups are so attractive as the ripe fruit. Scott's poison is no use whatever. By far the best way—and it is most effectual—is to keep the wasps outside the house, and this is easily done by fastening gauze over the ventilators. Hexagon netting lasts a long time, and the meshes are large enough to admit plenty of air, and sufficiently small to keep out flies of the bluebottle type. All decaying berries are promptly removed.

#### CUCUMBER AND MELON HOUSES.

Melons sown last month will have made rapid growth, and when the roots have fairly filled the small pots into which they were potted the plants may be turned out into the border. They are usually about 6 inches or a foot high when they are planted. Some sorts, such as Turner's Scarlet Gem, make compact short-jointed growth; others, as Trentham Hybrid, make long-jointed weakly growth, and the one would be much taller than the other at planting-out time. For the latest planting it is better not to have any manure in the soil, nor should the beds be very large. Good turfy loam of a medium clayey texture pressed in firmly will grow the plants well. If the loam is of a retentive nature a little leaf mould mixed with it will be very beneficial. When the soil is rich the fruit is not likely to be highly flavoured. In summer a richer loam is desirable. Plants in full growth and on which the fruit is set should have the laterals thinned out, and those that remain should be stopped a leaf or two beyond the fruit, and this must be done before they become crowded; the fewer the leaves and growths that are removed at one time the better. Ripening fruit must not be entirely shaded by the leaves; in northern districts it may be fully exposed to the sun, but a slight shade is better with us in the south.

Our Cucumbers have been in bearing since March. We shall now either sow seeds and have the old plants removed, or raise plants from cuttings. If only one house can be devoted to Cucumbers it will be necessary to grow the plants on in large pots, say 10 or 11-inch, until they are nearly in a bearing state, so that there may be no break in the supply. We do not give the plants a very rich compost at this season; if it is found that more support is necessary it may be given in the form of surface-dressings. The Cucumber plants when growing freely greatly enjoy this surface stimulant, the young roots working into it at a rapid rate.

#### PLANT STOVE AND ORCHID HOUSES.

We have now a change from the scorching hot weather of July. On several days the weather has been cloudy with rain occasionally, and the nights are colder, the atmosphere is heavier and moist, a different treatment is therefore necessary. The shading requires to be removed earlier at night, nor is it necessary to shade so early in the morning. Plants with leathery leaves, such as *Stephanotis floribunda*, *Ixoras*, &c., ought not to be shaded at all after this; and to do such plants justice a house ought to be devoted to them at this season, as the largest proportion of stove plants cannot safely be exposed to the direct

rays of the sun; those that can be so exposed require it to ripen the wood, so that it may the more perfectly produce flowers next season.

We have still been repotting specimen plants, but it is now time that all such work be brought to a close, as the pots ought to be pretty well filled with roots before the cold damp days of autumn set in. Amongst others *Anthurium Scherzerianum* has been repotted. This plant has thick fleshy roots, and they ought to be preserved as much as possible during the operation. The plant requires plenty of pot room, and about 2 inches of space should be allowed between the pot and ball of roots. The best potting material is tough fibrous peat, to which has been added a third part of fresh-chopped sphagnum, some potsherds, and pieces of charcoal; the pot ought also to be filled quite one-third of its depth with clean drainage. We do not care to repot Orchids after this time, but some of the species may require fresh compost. The best time to pot Orchids is when the roots start into active growth. Like the rest of the stove plants, they do not require so much moisture at this season, and to ripen their growth they have as much sunshine as they will bear with impunity.—J. DOUGLAS.

### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

- FILEY. August 11th. Mr. Walter Fisher, Hon. Sec.  
 OTLEY. August 12th. Mr. Alfred Suttle, Hon. Sec.  
 CLAY CROSS. August 15th. Mr. J. Stallard, Clay Cross, near Chesterfield, Sec.  
 EMSWORTH. August 15th. Mr. H. Moore, Hon. Sec.  
 WESTON-SUPER-MARE. August 15th and 16th. Mr. W. B. Frampton, Sec.  
 PRESTON. August 16th and 17th. Mr. W. Troughon, Hon. Sec.  
 SHREWSBURY. August 16th and 17th. Admitt & Naunton, Hon. Secs.  
 LEDBURY. August 17th. Mr. J. B. Masfield, Hon. Sec.  
 NORTON, NEAR STOCKTON-ON-TEES. August 18th. Mr. C. Turner, Sec.  
 MIFFIELD. August 19th. Mr. G. Senior and Mr. J. Rushforth, Hon. Secs.  
 CALNE (Wilts). August 22nd. Mr. H. Blackford, Sec.  
 NEWBURY. August 22nd. Mr. H. Seymour, Hon. Sec.  
 BAWTRY. August 22nd. Mr. J. W. Fritchley, Hon. Sec.  
 DORSET COUNTY. August 23rd (at Dorchester). Mr. A. Pope and Mr. C. Parsons, Secs.  
 CHEPSTOW. August 23rd. Mr. R. Thorn, Hon. Sec.  
 CARSHALTON, WALLINGTON, AND BEDDINGTON. August 24th. Mr. J. Baines, Leicester House, Carshalton, and Mr. W. Clark, the Nurseries, Wallington, Hon. Secs.  
 LARGS AND FAIRLIE. August 25th. Mr. D. G. Glen, Hon. Sec.  
 SANDY. August 25th. Mr. E. T. Smith, Hon. Sec.  
 SEATON BURN. August 26th. Mr. R. Richardson and Mr. W. Elliott, Secs.  
 ISLE OF THANET (MARGATE). August 30th. Mr. C. D. Smith, 8, Marine Terrace, Margate, Sec.  
 SHIRLEY, MILLBROOK, AND FREEMANTLE. August 30th. Mr. Jennings and Mr. Squibb, Hon. Secs.  
 POCKLINGTON. August 31st. Sec., Mr. J. E. Ross.  
 YARMOUTH. August 31st. Mr. S. Aldred, Hon. Sec.  
 THORNTON HEATH. September 1st and 2nd. Mr. W. Raines, 10, St. John's Villas, Bengeham Manor Road, Thornton Heath, Hon. Sec.  
 MONTROSE. September 1st and 2nd. Mr. Alex. Burnett, 2, High Street, Sec.  
 DUNDEE (International). September 7th, 8th, and 9th. Mr. W. R. McKelvie, 25, Euclid Crescent, Sec.  
 GLASGOW. September 12th and 13th. Mr. F. Gilb. Doughall, 167, Canning Street, Sec.  
 ROYAL CALEDONIAN HORTICULTURAL SOCIETY. September 13th.  
 KILMARNOCK. September 14th. Mr. M. Smith, 11, King Street, Sec.  
 IPSWICH. September 17th. Sec., Mr. W. B. Jeffries, Henley Road, Ipswich.  
 NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.  
 LOUGHBOROUGH (Chrysanthemums and Fruit). November 21st. Mr. John West, Chapman Street, Loughborough, Sec.

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

LIST OF ROSES IN POTS (*I. A. P.*).—You will find a list with cultural directions in a recent number, No. 791 New Series.

TACSONIA FLOWER BUDS FALLING (*A Lady Amateur*).—Want of moisture in the soil and air is the probable cause.

EARTHENWARE LABELS (*Newton*).—We have just seen some which are manufactured by Messrs. Hooper & Co., Covent Garden. They are white and handsome, and an indelible ink is provided, but they can be written on with a lead pencil.

DARK ROSE.—SOIL FOR ROSES (*X. Y. Z.*).—Alphonse Damaizin is deep crimson; Triomphe de Paris is purplish crimson. The best soil is a rather strong loam; the deeper it is the better. It should be well drained. Such land as will grow good Wheat or good Hops will grow fine Roses. Next, it

should be rich to grow them fine; if not already so, it ought to have thoroughly decayed dung added to it. A portion of superphosphate of lime (bones dissolved in oil of vitriol) will be of great benefit to them.

**CIDER (J. F.).**—Its quality varies as much as that of wine, and the variation is occasioned by the soil and climate as well as the kind of Apple from which it is made. Five centuries ago cider made from the Pearmain was preferred. Thus in the reign of Edward I. "Walter de Heven held the manor of Runham in the county of Norfolk of the king, rendering to him two measures (mutarum) of wine made of Pearnains."

**SEEDLING GLOXINIA (J. W. A.).**—The colour is crimson, but no one could say it is meritorious without seeing the plant.

**POTATOES SPROUTING (Somerset).**—Take them up at once and dry them before storing.

**WOODLICE ON CUCUMBERS (W. P.).**—Put slices of potato and a little moss in garden pots in the frame, and kill the vermin that resort to them.

**PETUNIA CUTTINGS (Idem).**—Petunias are easily propagated by cuttings from February to October. The best cuttings are the young tops of rather weakly-growing plants. In spring the cuttings require a gentle hobbed, but in summer and autumn they strike root readily enough in a cold pit or frame. The cutting pots should be drained in the usual way; then place a layer of rich, light, very sandy compost nearly up to the rim of the pot; and lastly, fill up the pot with fine silver sand; then give a gentle watering to make it firm. For the cuttings choose young weak shoots, and cut them off close to a joint, dress off the lower leaves so as to allow about an inch to be planted in the sand, and not more than three or four leaves at the top. Plant them with a short stick, pressing the sand closely to each. The pot may be filled with cuttings in rows across it, or, if space is plentiful, place them out round the edge. Observe that the holes made by the planting stick are filled up with dry sand; it runs more readily into the holes than moist sand would do; then give a gentle watering again, which firmly fastens the sand round each cutting; leave them on the bench for an hour to dry off the surface moisture. After that place them, if in spring, in a gentle hobbed, or if in summer or autumn in a pit or frame; shade from bright sunshine, and water when the surface becomes quite dry. Mind the watering-pot, and do not use it too freely upon cuttings until they are fairly rooted and show evident signs of having made roots and growth. Then give plenty of air and expose them fully. The spring and summer cuttings should be potted-off immediately when rooted; but those struck late in the year may remain in the cutting pots through the winter. When they are potted, whatever may be the period, they should be placed in a frame or pit where they can be shaded and kept close for a few days until fresh roots are produced; let them then be gradually inured to bear the full light and air.

**SEEDLING PANSIES FOR BEDDING-OUT (N. B.).**—The Pansies which you now have in bloom in a cold frame will not be available for making a bed for next year's blooming except by cutting away the flowering shoots gradually, which will encourage shoots from the bottom; but we should take cuttings of the side shoots—not the old hollow flowering stems—at the end of this month or beginning of September, inserting them in good light soil with a free admixture of sand under a hand-glass or in a cold frame, keeping moderately moist and shaded from bright sun. They may be potted off singly in 3-inch pots and wintered in a cold frame, planting them out in spring.

**STOPPING TOMATOES (Alex. Boyle).**—With due supplies of water and liquid manure every bunch of bloom and fruit now produced may remain. We should allow all fruit setting up to the early part of September to remain, as such will swell to a good size, and the fruit, though green, will ripen in a warm room. The fruit remaining after the plants go off from cold should be so treated. After the early part of September we should keep closely stopped.

**COMPOST FOR CYCLAMENS—SEEDLINGS (H. S.).**—Three parts of turfy loam, one part of leaf soil, one part of sandy peat, and half a part each of small charcoal and silver sand, will form a suitable compost. The loam and peat should be broken up small but not sifted, though it may be passed through an inch sieve, and the rough portion used for placing over the drainage in the pots. The plants may now be potted, the size of the pots being regulated by the size of the corms. The pots should be sufficiently large to admit of an inch to 1½ inch of space from the corms to the sides of the pot. They should be placed in a cold frame, kept moist, and shaded from bright sun, with moderate ventilation. The seedlings should be potted off singly and placed in a gentle heat in a frame kept moist and shaded, or in a cold frame kept rather close, removing them to a greenhouse in September or early October. Potted singly in 3-inch pots they will need a shift in the autumn into pots a size larger, and the strongest will flower next spring; but to do this the plants will require a warm greenhouse.

**CULTURE OF BERTOLONIA SPERBERISSIA (A Novice).**—It will only succeed without a glass in a moist and warm stove. If the stove be very airy it will be desirable to confine the glass, as this plant is impatient of a dry atmosphere. Bright light is also prejudicial to it, a subdued light being necessary to bring out its colours. It is one of the most beautiful of fine-foliage plants, and we have never seen it so well grown as under a bell-glass in Mr. Bull's nursery.

**PINE PLANTS NOT SHOWING FRUIT (C. B.).**—The reason that your Pines do not show for fruit is either that you have grown them on without a resting period or overpotted them. If the bottom heat is kept up at the highest point the plants have no resting period. They ought to be kept rather dry at the roots, and in a temperature of about 55° for six weeks or two months before starting them into growth. Ten and eleven-inch pots are quite large enough for Queens. This sort is about the worst for fruiting in winter. Smooth-leaved Cayenne and Black Jamaica are the best.

**VINES NOT FRUITING (A. G.).**—If the growth is very strong this year and the wood well ripened you will have plenty of bunches next season. It is not good culture to allow the laterals to grow as much as they like; you should pinch them back, as has been so frequently recommended in this Journal. When there is too much lateral growth the eyes from which the fruit will come next year have a lean and starved appearance instead of being plump and well developed.

**VINES ATTACKED BY RED SPIDER (A. B. V.).**—This pest can be destroyed in two ways—either by washing it off by syringing the Vines, or by painting the hot-water pipes with flowers of sulphur mixed in warm soapy water to the consistency of thin paint. The pipes should be heated so hot that the hand cannot be held on them more than a second or two; but the right degree of heat must be learned from experience. Thomson on the Vine is the best practical treatise for a young beginner.

**FAIRY RING (N. J. M.).**—As you propose to remove the turf, if you remove

2 or 3 inches of the soil beneath it also, that will eradicate the fungus which causes the ring. If you sprinkled common salt over the ring it would destroy the fungus; it would make the grass brown also, but this would gradually become green again.

**NAMES OF FRUITS (R. C. C.).**—The Pear is Doyenné d'Été.

**NAMES OF PLANTS (L. J.).**—*Funkia grandiflora*. (Harry Vidler).—*Sedum purpureum* probably. (Climber).—*Boussaingaultia baseloides*. (T. R.).—1, *Pellaea cordata* var. *flexuosa*; 2, small cristate var. of *Filix-femina*; 3, *Lycopodium japonicum*; 4, *Nephrodium decursivo-pinnatum*; 5, *Nephrodium Filix-mas* var. *abbreviatum*; 6, *Scelopendrium vulgare*. (G. H.).—They are Begonias, but there are too many varieties for us to name them.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### HEDGEHOGS v. CHICKENS.

I CAN give a similar experience with regard to hedgehogs as "W. W." has detailed on page 83. For some weeks past one old and two young hedgehogs had established themselves in my garden. Thinking they might be of service in killing slugs, &c., I carefully protected them from the attacks of my terrier, which used to hunt them out and carry them on to the lawn for my approval. At last they seemed thoroughly domesticated, and might be seen any evening about dusk patrolling the lawn in search of worms. A few nights ago just before going to bed I heard a great commotion in my fowl yard, where a hen used to brood her ten-weeks-old chickens in a corner on a heap of rubbish. On rushing out with a light I found chickens squatting all about the yard in a great state of fright, and the hen groping her way to the hen house with some of her brood, the rest being huddled in the corner where they slept, screaming vigorously. Close to them on the heap stood one of my young protégés, so ashamed of himself at being caught in such an ungrateful act that he forgot to roll himself up. I killed him, and on his forepaws I found evidence of his guilt. They were quite covered with mortar and rubbish from scratching to get under the hen, while his hind feet were quite clean. There could be no slugs or food fitted for his palate in a heap of broken bricks and lime; and the hen was a particularly bold and fond mother, and I am sure would have never stirred unless a direct attack had been made. It is needless to say that the mother hedgehog and her surviving child were hunted out next night, and safely transferred to a field on the other side of the river, where they can indulge their useful propensities and do no harm to anyone. A neighbour has since informed me that some years ago he also found a hedgehog with a dead chicken in his fowl house. I have often argued with keepers for their preservation, but I am afraid now I must include them among the foes to game.—C. K. E.

### HEWORTH SHOW OF POULTRY, &c.

THIS was held in connection with the horticultural exhibition in the grounds of Tang Hall, which had been kindly placed by Mrs. Starkey at the disposal of the Committee. The poultry, besides being more numerous than last year, was also superior in quality. Last year the entries numbered 106, while this year they increased to 212. A commendable class of Cochin-Chinas was penned, the other varieties being well up to the mark. A large number of commended cards were required when the Pigeons were judged. The class for Pouters or Carriers was generally commended, while many cages in the Barbs were similarly ticketed. The class for Fantails or Trumpeters, though a small collection, contained some pretty birds, while the show of Antwerps or Dragons was a very fair one. The Rabbits were good. Amongst the class for buck or doe of any variety as many as nine commended cards were distributed. The Cage Birds were, on the whole, not a first-class lot, though the Dark-crested Canaries were very good. The evenly-marked Canaries were only moderate, but the Clear Yellow and Buff were superior birds. The prize birds in the class for Crested Yellow or Buff richly deserved the honour awarded them, as did also the two birds which formed the Bullfinch class. Though a success in the number and quality of the exhibits in each department, the financial success of the Show was considerably marred by the unpropitious weather which prevailed in the afternoon.

**JUDGES.—Poultry:** Mr. Joseph Walker, Birstwith, Ripley. **Pigeons:** Mr. George Fletcher, Acomb Landing. **Rabbits:** Mr. R. Dobson, York. **Cage Birds:** Mr. George Clarke, Scarborough.

### DRIFFIELD AGRICULTURAL SOCIETY'S SHOW OF POULTRY, &c.

THIS was a good Show, and the greatest improvement had been effected by securing Turner's pens in place of the dirty old skeps which had been used previously. Unfortunately the weather was wet, and there being no covering the birds were sadly wetted while judging, and it would be well to secure a tent for future shows.

*Brahmas*, first Light, and second Darks. *Spanish* poor, but the prize-winning *Game* good. In *Hamburgs* were a few good birds, notably the first Gold-pencils. *Bantams*, first and second Blacks. In the Variety class Gold Polish were first, Black *Hamburgs* second, and Guinea Fowls third. *Ducks* nothing of special note except Messrs. Sylvester's birds of the ornamental variety.

*Pigeons* suffered much from exposure and were very difficult to judge. Mr. Baker, taking the Show on his way from Bramley, made the Show much better. Carriers, Mr. Baker was first and third with well-known birds. Pouters, first Blacks, second Whites, and third Blues, very good and well placed. Jacobins, Red, good in hood and chain properties, but rather low out. Fantails a nice lot. Tumblers, first and third Almonds, and second Whites. Dragons, first and second Blues, and third Silvers. In Turbits a local breeder had eleven entries, but Mr. Baker ran away with the first with grand Silvers. In the Variety, first were Trumpeters, second African Owls, and third Barbs.

**POULTRY.**—*BRAHMAS*.—1, T. P. Carver. 2, W. H. Garford. *COCK*.—1, J. Walker. *DORKINGS*.—1, W. Lesson. 2, R. Smith, jun. *COCK*.—1, D. White. *SPANISH*.—1, R. Stabler. 2, G. Mr. Cannan judged all except Game and Game Bantams, which were judged by Mr. Smith.

## HORTON SHOW OF POULTRY, &c.

THE annual Show was held on the 5th inst., and was in all respects similar to its predecessors. Fortunately the weather was much better than last year, and the birds being shown in the open field this was very fortunate.

*Game* were a moderate lot, the cup going to a pretty good Black Red cock that has often won of late. Cockerel and pullet *Game* were first Duckwings, and second Brown Reds; the first a nice well-grown pair. *Spanish* and *Bantams* pretty good. The Blacks were first and second. *Hamburgs* were small entries, but the birds very good. The cup given by Mr. Ackroyd was awarded to a pen of Buff Cochins.

*Pigeons* had more entries than poultry, the cup being awarded to a Yellow Barb cock. Blacks won in Carriers. The cup birds at Saltaire were rightly left with only a commendation. Dragons—first Silver and second Blue. English Owls a fair lot, Blues winning. Turbits—first Silver and second Yellow, the latter the best. Antwerps with six classes had only thirty-four entries, which we look upon as very poor with £1 and 10s. as prizes in each class; the birds were, however, the pick of the Yorkshire birds. The Variety class had twenty entries—first, a Mottled Tumbler and second Red Jacobin.

*Rabbits* had three classes, with twenty-four entries. Lops were poor. Himalayans were very good. Pen 3 (highly commended) was very small and young, but otherwise best. Any other variety—first a young Silver-Grey buck, second an Angora. One Dutch was shown, and the rest were Angora and Silver-Grey, the latter very good. Mr. Firth's well-known doe was left out.

**POULTRY.**—*GAME*.—*Brown Red*.—*Cock*.—1, E. Lund. 2, C. Thornton. *Black Red*.—*Cock*.—Cup and 1, R. Hemingway. 2, H. C. & W. J. Mason. *Black or Brown Red*.—*Hen*.—1, J. W. Thornton. 2, E. Lund. *Any other variety*.—*Cock*.—1, H. C. & W. J. Mason. 2, W. Milner. *Hen*.—1, H. C. & W. J. Mason. 2, H. Wood. *Any variety—CHICKENS*.—1, T. Dyson. 2, W. A. Fenwick. *SPANISH*.—*Black*.—1, J. Powell. 2, H. Beldon. *COCHIN-CHINA*.—1, W. Mitchell. 2, C. Sedgwick. *BRAHMA FOOTER*.—1 and 2, W. Schofield. *ANY VARIETY EXCEPT GAME AND HAMBURGS—CHICKENS*.—*Extra* and 1, C. Sedgwick. 2, J. M. S. Karratt. *HAMBURGS—Silver-spangled*.—1 and 2, H. Beldon. *Silver-pencilled*.—1 and 2, H. Beldon. *Golden-spangled*.—1 and 2, H. Beldon. *Golden-pencilled*.—1 and 2, H. Beldon. *Black*.—1 and 2, H. Beldon. *Any variety—CHICKENS*.—1, C. Sedgwick. 2, G. Moore. *ANY OTHER VARIETY*.—1 and 2, H. Beldon. *BANTAMS—Game*.—1, W. F. Entwistle. 2, A. S. Sugden. *COCK*.—1, J. Blamires. 2, H. Wood. *Any other variety*.—1 and 2, C. & J. Hingworth. *DUCKS*.—1, J. Newland. 2, J. R. Pollard.

*PIGEONS*.—*CARRIERS*.—*Cock or Hen*.—1, H. Yardley. 2, J. Cockitt. *DRAGONS*.—*Cock or Hen*.—1 and 2, R. Woods. *OWLS—English*.—*Cock or Hen*.—1, E. Thresh. 2, W. Ward. 3, R. Woods. *TURBITS—Cock or Hen*.—1 and

2, R. Woods. *TUMBLERS—Long-faced*.—*Cock or Hen*.—1, B. Rawnsley. 2, R. Woods. *BARBS—Cock or Hen*.—1 and 2, H. Yardley. *ANTWERPS—Long-faced*.—*Cock*.—1, W. Ellis. 2, S. Wall. *Hen*.—1, H. Jennings. 2, J. Cockitt. *Short-faced*.—*Cock*.—1 and 2, W. F. Entwistle. *Hen*.—1, J. Ackroyd. 2, W. F. Entwistle. *Medium-faced*.—*Cock*.—1, W. F. Entwistle. 2, W. Ellis. *Hen*.—1 and 2, W. Ellis. *BIRD FOR FLYING PURPOSES*.—1, H. Jennings. 2, W. Ellis. *ANY OTHER VARIETY*.—1, H. Yardley. 2, T. Holt.

*RABBITS*.—*LOP-EARED*.—*Buck or Doe*.—1, W. T. Millett. 2, A. Hawley. *HIMALAYAN—Buck or Doe*.—1, Townell & Chappel. 2, H. Berry. *ANY OTHER VARIETY*.—1, Miss Firth, J. Firth. 2, R. Margatroyd.

JUDGES.—Messrs. Dixon and Charlton.

## CLEVELAND SHOW OF POULTRY, &c.

THIS Show was held at South Stockton on the 27th ult. in connection with that of agriculture. The list was a fair one, but other shows interfering the entries were not numerous. As usual a tent was provided, and the pens were well arranged.

*Spanish* were a fair lot. The first-prize *Dorkings* were very good; and in *Cochins* were three splendid pens. In *Game* Reds the winners were Brown Reds, and in single cocks first was a capital Brown Red. *Game Bantams*, first very stylish Black Reds. In *Hamburgs* first Gold-pencils very good, the Silvers only moderate. Variety class first Malays, and second Houdans, the latter very large.

**POULTRY.**—*SPANISH—Black*.—1, H. Dale. 2, T. Flintoff. *DORKINGS*.—1, T. P. Carver. 2, E. Barker. *COCHINS*.—1 and 2, G. H. Prestor. *BRAHMAS*.—1, T. P. Carver. 2, G. B. Bell. *GAME—Reds*.—1, G. Holmes. 2, H. E. Brown. *Any other variety*.—1, G. Holmes. 2, W. Scott. *COCK*.—1, G. Holmes. 2, Blackburn & Maynard. *BANTAMS—Game*.—1, W. Britain. 2, G. Holmes. *Any other variety*.—1, R. H. Ashton. 2, Rev. H. A. Hawkins. *COCK*.—1, R. H. Ashton. 2, G. Pounder. *HAMBURGS—Golden-pencilled*.—1, T. P. Carver. 2, T. & G. Kidson. *Silver-pencilled*.—1, G. Holmes. 2, W. Storey. *Golden-spangled*.—1, G. Holmes. 2, T. P. Carver. *Silver-spangled*.—1, G. Holmes. 2, J. Ashworth. *POLISH*.—1, J. T. Freud. 2, Rev. J. G. Milner. *ANY OTHER VARIETY*.—1, R. Hawkins. 2, Rev. J. G. Milner. *ANY VARIETY OF CROSS*.—1 and 2, G. Foster. *DUCKS—Aylesbury*.—1, F. Waller. 2, W. Stonehouse. *Rouen*.—1, T. P. Carver. 2, Rev. J. G. Milner. *Any other variety*.—1, R. H. Ashton. 2, Rev. J. G. Milner. *GEES*.—1, Miss E. Stephenson. 2, G. Pounder. *GOSLINGS*.—1, G. Pounder. 2, C. J. Young. *TURKEYS*.—1, Miss Kirk. 2, T. P. Carver. *POULTS*.—1, Miss Kirk. 2, R. Dodsworth.

*RABBITS*.—*LOP-EARED*.—1, W. Bulmer. *ANY FANCY BREED*.—1, S. S. Robinson. 2, W. Bulmer.

Mr. Cannan judged.

## OSWESTRY POULTRY SHOW.

UNDER great patronage the Oswestry Show was held this year in Brynlyn Park in a large tent. The pens were all on one tier, and their inmates were well cared for, the birds coming from a distance being speedily packed-up and dispatched at the close of the Show.

*Game* were as usual strong classes, and the quality was good, though many birds were out of feather from the time of year. The Brown Reds were better than the Black Reds, a good pair winning, the cock stylish and smart in head. The cock in the third-prize pen was a good undubbed bird. In Duckwings a smart pen was first, the cock good in shape and style; good chickens won third. *Dorkings* mustered fairly; the first-prize were a fine pair of dark birds, but the earlobes rather too white; the second-prize pen had a moderately good cockerel; 26 (Darby) was empty. In variety *Dorkings* excellent Silver chickens were first, the pullet a very promising bird; second also went to Silvers, the cock being of fine colour for the time of year, though not a large bird; 32 (Badger) empty. Partridge *Cochins* only mustered two pens of moderate quality. In Buffs the first cock was very shapely, but rather pale on wing; his companion was also good in shape, but had a very ugly comb. Second went to well-grown chickens; the pullet, however, seemed loose in wing. The third cock was pale in colour, and we liked either of the highly commended pens quite as well. In the next *Cochin* class good Blacks won first and second with really very little between them. The first cock was a little high in tail, and his hen not sufficiently leg-feathered. Third went to Whites; the cock the fine bird which won first at Bristol, with a hen of much quality, but not very clean; 41 (Boissier) a moderate pen only. *Spanish* were only small in numbers; first and second good pens, but rather wrinkled in face; third not superior, and of bad colour in face. In Dark *Brahmas* we found a good pullet in the second pen. Lights were good, and the first were large and well feathered; second went to capital chickens; third also a good pen, but the cock was too yellow. In Pencilled *Hamburgs* a smart pen of chickens (Silvers) were first. In Spangles Gold were first and third, Silvers second. In *Houdans* the first were large, but the cock had a swollen toe; 68 (Naylor) empty; second prize went to forward chickens. In the Variety class all the prizes went to White-crested Black Polands, and capital pens they were. This well illustrates our remark of last week, that the breed is rapidly gaining ground in quality and popularity. The first cock was a gem; he had the most perfect crest for colour and shape possible, and was in fine trim; second were also good, but the cock rather yellow in crest; the third contained an exquisite hen with a perfect crest. In *Game Bantams* a good pen of Brown Reds won first, Black Reds of fair quality second, and Duckwings third; while in the next class capital Silver-laced were first and

loosens and rots the quills, and encourages a continual pecking at and mutilation of the feathers by the birds. When meat is supplied (only occasionally) it should be either on the bone of a rabbit or fowl, which said bone should be pretty well polished of the meat before it is given to the Parrot, for the trouble and exercise it would afford Polly in denuding the bone of what little it had on would really do the bird more good than if a free use of meat was otherwise placed before it.

Those who keep Parrots for their amusement should understand that it is their duty to amuse them and make the birds as familiar as possible. Let the word "kindness" be the keeper's watchword in guiding them in their duty, allowing no one to disconcert or harshly treat "poor Polly." One matter which we have often noticed neglected is the placing of a Parrot in a cage with only a bare perch for it to amuse itself with. In a cage where there is much woodwork a Parrot will soon show proof of its wood-carving propensity. Indestructible metal cages are preferable, with a swing for the bird. One of the most amusing Parrots we have come across (a tolerable chatty bird too) had suspended from the top part of the cage a couple of chains, each a foot long, with which it was interesting to see the bird climb up and swing by. The chains were first suspended inside the cage by chance, owing to them slipping betwixt the wires when the cage was detached from the ceiling to be cleaned out. They were ever afterwards allowed to hang inside the cage, much to the pleasure of the Parrot. The bird found continual amusement thereby, and was kept in good action by its irregular movements. No doubt this conduced to its general good health.

We have not much fault to find as to your general treatment, but we would prefer soaked Indian corn and bread and milk as the staple food, with meat or fruit occasionally for a change. Some use their birds to hemp seed, others to bread and milk, and we have noticed, out of many hundreds we have come across, birds apparently enjoying good health under various treatment as to diet. We much approve of occasional shower baths for Parrots. By all means discontinue the use of butter; bread soaked in milk is far preferable. The stomach of your bird is in a weak condition, and butter will increase the vomiting which occurs over the disease your bird is suffering from. Give the sufferer two or three drops of castor oil twice a week, and a shower bath every other day, after which latter administer a little weak brandy and water, and then dry the bird gently before a fire. If the bird will permit you to handle it, all well and good, but if it bites cover your hand with a cloth and lay firm hold of the back part of the bird's neck whilst giving it the castor oil. A little piece of pine apple or other ripe fruit may also be given.—GEO. J. BARNESBY.]

## POULTRY AND BEE NEWS AND QUERIES.

**SEPARATING HONEY FROM WAX.**—Put the honey, comb and all, in a tin pan on a moderately warm stove, adding to each pound of honey a tablespoonful of water. Stir it occasionally with a piece of wire when the contents of the pan are perfectly liquified. It must not boil. Set it where it can cool undisturbed; then pass a knife carefully around the pan to detach the cake of wax on the top, and rapidly with great care lift off the cake. Don't let it drain into the pan an instant, but place it in another utensil. Anyone thus clarifying honey will find, on putting aside the cake of wax, that the impurities that would otherwise have to be strained from the honey will have adhered to the cake of wax, while the honey beneath is clear. If the honey should in time candy, heat it again with a very little water and brown sugar. Keep it in jars tied up in a cool place. Break up the wax cake and wash it in cold water till cleansed of honey; then melt and strain it. To bleach the wax, boil it, after straining for an hour in plenty of water, in which use a few drops of chloride of soda. When quite cold lift off the wax and leave it to dry and whiten in the open air.—(Housekeeper.)

## HONEY HARVEST.

To commence the season I had four stocks in round wooden hives 16 inches by 12, and five of last year's swarms in home-made bar-frame hives 18 by 16 inches, and 11 inches deep; and the weather last summer was so bad about here that after June went out the bees could not gather as much as would keep them. Consequently my new hives were not nearly half filled with comb; but I lost none during the winter, and by feeding this spring till the middle of May I managed to keep them all alive. But there was very little done with them till the third week in June, and then they began to work in earnest. The round hives that were already full of comb were quite filled with honey and brood by the end of the month. I put glasses on three old hives the last week in June, and the bees began working in them at once. I had the first swarm on the 3rd of July, and two other old hives about ten days later.

I have seen it stated in bee books that after the bees have swarmed it is no use leaving the glasses on; but I left mine on,

and they have filled two of them since. The one that swarmed on the 3rd of July I drove on the 23rd, and as it was the first time I have tried driving I was agreeably surprised to find it such easy work. The contents of the hive weighed 49 lbs., and there was 23 lbs. of splendid honey in the glass, making 72 lbs. for that lot of bees. The same day I took a 10-inch glass off one of the other old hives and put another one on. It was quite filled with beautiful white comb, sealed all over, and weighed 18 lbs. nett. I intend driving the bees from that hive and the other one that has swarmed this week, and they feel quite as heavy as the first one. My bar-frame hives are all quite full, and are very heavy, but only two of them have begun work in the super. When would be the best time to take some honey from them? And last Sunday I saw that one of the others had cast out some young unhatched drones, and last night I saw some outside another hive.

Your readers do not need to be at a loss for a pair of good bee gloves. My wife made me a pair in five minutes at a cost of about one penny, and with them I am quite safe from bee stings, and besides can handle and use anything I may require in my operations with the bees. They are simply two strong calico bags made wide enough to spread the fingers inside, and long enough to tie well over the cuff of the coat, with a pad of wadding or any similar material stretched inside to come over the back of the hand. They are not very handsome to look at, but they can be taken off sooner than one can reduce the swelling from bee stings.—G. G., Billinge, near Wigan.

## FRAME HIVES AND THE EXTRACTOR.

FROM all parts come the glorious news of an extraordinary glut of honey, one gentleman (of whom probably more anon) writes to me that he has sent away 500 lbs., 200 lbs. just going, and he has twice as much left! Up to the middle of June the bees did nothing (except in favoured localities from the fruit blossoms), then all at once with the brilliant summer weather the hives and supers filled fast, and until towards the third week of July the busy little workers literally toiled themselves to death. Now with us, where there is no heather, the harvest is over, and the sooner it is gathered the larger it will be found.

Now comes the advantage of frame hives and the extractor. Our American friends incline to the opinion that stocks that are wintered on sugar syrup are much more likely to survive till spring than stocks which are allowed their own stores. There is probably reason in this, as much honey is infected with the germs of foul brood, and when extracted and replaced by pure sugar the latter is, of course, likely to be more wholesome for the bees. Independent of this theory, we know that syrup is acceptable and good food, and as at the present free-trade price of sugar it can be made at less than 3d. per lb., and honey is saleable at three or four times that price, it is true economy to make the exchange. The extractor has been familiar to me in the hands of others for two or three years, but this season for the first time I have owned one, which was exhibited last year at the Crystal Palace by Mr. Cowan, and right well has it done its work. The combs subjected to its influence have been completely emptied of honey, and with proper care no injury need be done to the brood. Of course, a careless workman may turn so fast that the unlucky brood will come out with the honey, or so slowly that nothing comes out; but there is a rate of speed soon discovered which is sufficient to fling out the heavy liquid and not interfere with the lighter larvae. My machine having done duty at home is now on its travels to my friends, several of whom have expressed their delight and satisfaction at the abundance of honey it places at their command.

There is another advantage which is very patent after using the extractor to strong stocks. I speak of the impetus it gives to breeding, and I will instance a stock which had given me a super, on the removal of which I found the combs below full to repletion of brood and honey; the latter I at once extracted. The now emptied outside combs which had no brood were placed nearer the middle, and also a judicious distribution was made of the other combs that had many empty cells. In a few days the queen had taken possession and filled nearly every cell with eggs, so that the hive is now full from end to end of the embryo population for the winter, one of the most essential things for wintering being that the bees shall be young and vigorous, for a stock to be made-up of old bees for winter is simply dooming it to destruction. By keeping a hive full of brood in this manner it is easy by exchange of combs from it to assist a weaker stock, or one where the queen is not sufficiently prolific.

In regard to many queens I feel convinced their breeding powers are not utilised to the utmost, and that they lay vast numbers of eggs out of the cells, which fall to the ground and are wasted. This is especially the case where empty cells are scarce. I have many times seen a queen hopelessly walking about apparently dazed, and presently an egg would appear and drop from her. I have seen it directed as a means of ascertaining if a stock or swarm has a queen, to set it overnight on a black

cloth, and if a queen is there eggs will be found in the morning on the black ground. Certain it is that in June last I found abundance of such dropped eggs in a cloth that had been tied round a skep containing a swarm.—JOHN HUNTER, *Eaton Rise, Ealing.*

### FILLING SUPERS AND FRAMES WITH HONEYCOMB.

MR. HUNTER says that "Mr. Pettigrew's idea of filling small frames with such combs [honeycombs cut from honey hives] and then giving them to the bees to clean and fix will be found a failure. The bees' first and only idea would be to fill their hive, and to do this they will very quickly empty the strange combs. I have tried it and know it fails, although I gave them a much better chance than Mr. Pettigrew promises with his unfurnished hive." This is very plain and honest language, and I am sure that Mr. Hunter and the readers of the Journal will now permit me to speak as plainly and honestly as he has done. He has not tried my plan, and therefore does not know that it will fail. I have tried it again and again, and in my hands it never fails. The two instances that Mr. Hunter brings into view are not to the point at all. He presented strange combs and new honey to full hives. He might have anticipated failures, for this was a temptation too strong for any bees, for they instinctively fill their own hives, and will carry honey both upwards and downwards and from every quarter to fill their own combs. But if they have no combs of their own to fill what will they do with the honey given to them? Where will they carry it to? Mr. Hunter has yet to consider this question, and try an experiment or two. Shall I be permitted to suggest one or two which may be of considerable and permanent importance to bee-keepers generally?

1. Let the frames of a hive be filled artificially as well as possible with honeycombs cut from honey hives, and placed over a good swarm in an empty hive. The bees will not carry an ounce of honey below. Instead of doing this they will commence fixing the combs in the frames, and if honey in quantity be given to them in the bottom (empty) hive, they will carry it aloft and store it in the combs thus given to them. This is a very short and easy way of filling frames with virgin honeycomb, and I sincerely trust that many poor bee-keepers will by it be enabled to convert their honey hardly saleable at 10d. into a form readily saleable in any market at 1s. 6d. per lb.

2. Let a super of any kind or size be filled with honeycomb, sealed or unsealed, and placed in like manner on a swarm of bees in an empty hive, and fed with honey either extracted or in broken combs. All the honey will be carried aloft, and the super will be found unobjectionable from every point of view, and saleable in any market. This is not an idea as Mr. Hunter calls it, it is an old practice which I unfolded in the pages of this Journal three or four years ago. In the interest of bee-keeping, for the advantage of both amateurs and bee-farmers, I ask that these experiments be widely tested.

Experience after all is the best teacher, and sure am I that those who demur at my plans will yet believe in the possibility of filling bar-frames with honeycomb artificially, and filling them as easily with full combs as those at the Crystal Palace first show were filled with tough black old combs. Notwithstanding Mr. Hunter's present "positive negative," I believe he will become a robust and able teacher of the practice. Beyond this he and others will go and learn another lesson—namely, that it is possible to prevent bees from carrying honey from supers artificially given to them. At present they are not able to bear it.—A. PETTIGREW.

### OUR LETTER BOX.

**PACKING HONEYCOMB (J. C.).**—Honeycombs cut from hives are not easily packed for travelling. In cutting the combs out they should be first laid on some kind of wickerwork or basket lid, to let the honey from the broken cells drain into a vessel beneath. In a couple of hours they could be packed in boxes on their edges or in their natural position, touching and supporting one another. We fill handled baskets thus for delivery by messengers. If we were sending 40 or 50 lbs. in a box to a distance we should pack the combs as they are built in hives, throw a swarm of bees amongst them, and lid them down for thirty-six hours. The bees would lick the combs dry, and fasten and prepare them for travelling. "J. C.'s" own ingenuity will help him more than anything we can say.

**BEE MANAGEMENT (E. M. E.).**—You have a very correct knowledge of the management of bees, and we are pleased to hear of yours doing so well this season, which as a whole has not been a favourable one for honey-gathering. As Nos. 1 and 2 of your stock are in hives inconveniently large and heavy for a lady, you may drive their bees out now and take their honey. The brood in them will be sacrificed, but by putting the swarms into smaller empty hives and feeding them well for a few days fresh combs would be speedily built and filled with brood. When the super on No. 3 shall be filled take it off and drive the bees of the hive into an empty one, and feed them into a stock, or unite them to the bees of 1 or 2. No. 4 will be strong enough without any extra bees—at least, stronger than any of the rest. Nos. 1 and 2 should be killing their drones now.

**HIVING A SWARM (Mrs. Elvington).**—You can certainly now drive the swarm you speak of with safety; only be careful in the act of driving, espe-

cially if the weather be hot, as the combs will be more or less delicate and brittle. You will, however, at this time probably find a good deal of brood in it. We should prefer waiting till September.

**TAKING HONEY (Smallwood).**—Your first attempt at taking honey from a hive has not been very agreeable—perhaps not very successful. After driving the bees into an empty hive you should have destroyed the stragglers left behind with sulphur or chloroform, then removed the honey hive indoors, and there take the combs out one by one. The operation is very easy, and well understood by all the cottage class of bee-keepers. Taking and running honey is never a pleasant occupation, but it must be done. We drive our bees into empty hives, sulphur the few remaining stragglers to death, take the honey hives without a living bee in them into a hothouse, and there withdraw the cross sticks, remove the combs into milkpans, and then run the honey. From the commencement of driving to the jarring-up of the honey it takes about an hour to do the work of a hive containing 25 lbs. Though unpleasant the work is simple and easy. The nearest bee-keeper will show you how to do it.

**WAX MOTH (Amateur).**—Usually in this country a strong hive will successfully keep off the wax moth. We know no way of preventing the ravages of these pests except by personally watching for and destroying them whenever they are seen; also we carefully avoid leaving empty comb about. The only way to destroy them in empty hives is to cut out and destroy every comb or part of a comb in which they have taken up their quarters.

### REMARKS.

2nd.—Very fine day throughout, but barometer falling rapidly.  
3rd.—Wet morning, but soon clearing off, and followed by a very fine day.  
4th.—Dull though fair in the morning; very showery all the after part of the day; at times the showers were rather heavy.  
5th.—Fine throughout the day, though looking rather stormlike about 6 P.M.; very fine night.  
6th.—Fine day, rather cloudy at times; rain at a distance at 7.30, and a very slight shower here.  
7th.—Rather dull early, but very fine after 9 A.M., and a splendid day, but very hot, though there was a very pleasant breeze.  
8th.—Another very fine day, and very close in the evening.  
No feature calling for special notice, unless it be the uniformity of the maximum in sun—viz., within 1° on four consecutive days, and within less than 5° throughout the week.—G. J. SYMONS.

### COVENT GARDEN MARKET.—AUGUST 9.

PRICES of soft fruit are somewhat lower this week, buyers being pretty well full, and all samples showing signs of the finish. The demand for hothouse fruit is also falling off, while the supply seems as plentiful now as any time during the season. The first Kent Fiberts have arrived.

From observations taken near London during forty-three years, the average day temperature of the week is 72.5°; and its night temperature 49.8°.

## PLANTING VINES.

VINES are planted in nearly every month of the year. Some approve of planting in early spring; others in summer and autumn. Success to a certain extent may be secured at all times, but there are some periods preferable to others. Planting in spring before growth begins, is perhaps the system most practised. Both root and branch are then in an inactive state, and after planting it often takes a considerable time before the

Vines are fully started into growth. Very frequently when they do begin to grow it is very irregular. One will start a few buds at the bottom of the cane, another will push from the extreme end, and a third may grow freely from every eye. From this it would appear that it all depends on how the roots start into action. Where the whole roots start into growth vigorously robust top growth soon follows; but, on the other hand, where only a few of the roots live and the others perish, as is not unfrequently the case, weak and imperfect leaf and wood development is the result. Of course there are instances where housefuls of spring-planted Vines do well, but cases opposite to this could be mentioned.

May is the month when Vines are generally planted in a "growing state." The Vines are propagated from eyes in February, and grown on until they have a stem a number of feet in length. At this stage the roots are generally in a free-growing condition, and when planted carefully growth continues without ever receiving the slightest check. By autumn the roots have become established in the border, and when heat is applied the following spring every root is ready to begin action without having to settle or find its way into a place. Vines treated in this way are generally as far forward by the end of the first season as spring-planted Vines are by the end of the second season. The present is also an excellent time to plant Vines. Vines which were propagated from eyes in spring will have been stopped long before this, and the lateral growths will be growing freely. At this time the roots are nearly as active as in spring, and to turn them out of the pots and plant them now the roots push into the border and become established before growth ceases. Two vineries which were planted the third week in August last year have made most satisfactory progress this season. The varieties are chiefly the Black Hamburgh, Muscat of Alexandria, Lady Downe's Seedling, Gros Colman, Alicante, and others. Golden Queen, although a weak cane when planted, is one of the strongest now. Duke of Buccleuch (two canes from a root) has been stopped at the top of the house long ago, and is now putting out lateral growths as strong as many leading rods.

After they were planted a few fresh leaves formed on each shoot before ripening off. The lateral shoots were pruned in close to the main stem about midwinter, and the principal canes were left their full length. When they were tied to the wires, instead of taking them straight

up, each cane was turned off in a slanting direction at about 2 feet from the ground. In spring every bud started into growth without any trouble. The two shoots nearest the bend of the cane were trained up as rods for next year, and each shoot along the slanting part of the cane was stopped when about a foot long. Bunches of fruit appeared on many of them, and from two to five were left on each cane. These are ripe and in good condition, and are being cut now. The old wood up to where the top leading shoot branches away has swelled four times the thickness it was last year, but beyond this shoot it has not thickened an eighth part of an inch. Although the fruit has swelled as on ordinary Vines, the sap appears to have been drained into the leading shoots.

All Vines that I have to deal with in future will be treated in this way. Planting in autumn when the wood and leaves have become well hardened there is little danger of the Vines receiving a check; whereas in spring or early in summer, if they are subjected to the least cold or anything of that sort it may spoil their whole season's progress. By planting now, there are more roots to disentangle than earlier in the season. The long roots should be laid straight out, and none of the small fibres must be broken. I do not plant deeper than will just keep the top of the ball under the soil. In autumn a thorough watering to settle the roots is found sufficient, but I never allow the soil to become dust-dry about the roots throughout the winter, and with plenty of drainage underneath Vines cannot have too much water in summer.—VINE-GROWER.

## LESSONS OF THE SEASON.—No. 2.

## SPRING.

IN watching the changes of the seasons and in striving to learn the lessons which they teach, one cannot fail to be strongly impressed with the intimate relation of season with season and the important effect of one upon another. A cold spring with its sluggish sap-action, and tardy, often weakly, growth is more than counterbalanced by the additional vigour of the ensuing midsummer shoot; the value of the stunted but thoroughly matured growth of a hot dry summer is not fully appreciated till its clouds of blossom and clusters of fruit render thinning necessary in the following season. The alternating clouds and sunshine of autumn and the frost and snow of winter are all causes of certain future effects—primary sources of good or evil to come. A knowledge of these facts renders us more keenly alive to the equally important one—that almost everything we do is for a future time and not for the immediate present.

To apply this reasoning let us take the Potato: as we lift the crop the seed is selected and not thrown in heaps, but is at once laid carefully on end upon shelves in single layers with the eyes uppermost, our present object being to prevent premature sprouting; our future one to induce such a slow and vigorous development of the sprouts that planting need not be hurried on nor done at all till the soil is in a suitable condition. This spring the seed of the

early Potatoes remained on the shelves till the whole of the late kinds were planted, many of the early kinds not being planted till the last week in April, and yet the whole of them were lifted and housed in twelve weeks from that time. Late planting is, therefore, not incompatible with early lifting. We have only to store the seed well at the time of lifting and then calmly await a favourable planting-time when spring comes round again. It is most important that this should be made quite clear to those who have not yet tried the plan. I may therefore explain that when Potatoes are stored in single layers upon open shelves the sprouting, which is inevitable, is so wonderfully robust—often being as large as one's finger—that when the planting is done the haulm springs up as if by magic, and with a strength and uniformity which is most gratifying, affording a striking and agreeable contrast to the weak uncertain growth of seed that is heaped or otherwise mismanaged.

The keen cutting winds from the north and east that were so prevalent in spring taught a lesson of much importance—half learnt long ago, of the necessity and value of shelter for all kinds of fruit trees. I say half learnt advisedly, for while one is accustomed to see blossom affected by exposure to cold, yet it is something new to have the foliage of Apples and Pears battered to shreds by the wind, and that, too, after it was grown to full size and become tolerably stout in texture, as was the case this year with many of the trees standing out in single rows along the side of kitchen-garden paths. In an orchard only the outside rows on the windward side suffered, and these were not so much affected as those in the kitchen garden, which proves that such trees shelter each other when planted together in large numbers. Thick belts of Larch and Spruce Fir form admirable wind screens, and it is intended to plant such a belt along the north and east sides of an orchard to thicken and make perfect the shelter which already exists in the form of a number of Oaks and Beeches. In doing this care will be taken to bring the belt as near as possible to the orchard boundaries, and yet not so near as to shade the fruit trees. An open trench 4 feet deep will be made and maintained close along the orchard fence to prevent any encroachment of the Fir roots, and the trees will be planted 4 feet apart, having Spruce only in every third row, and only every third plant to be Spruce in that row, all the other trees to be Larch, which would bring the Spruce 12 feet apart, with the view of gradually removing the Larches, so as eventually to form a dense screen of evergreen Spruce trees.

Some Peach and Nectarine trees on the outside of a south wall had the foliage much blistered by the cold east wind which swept along them with unchecked violence. Upon the principle that the best remedy is the right one, a permanent screen in the form of a wing of brickwork 20 feet long and of the same height as the garden wall is to be attached to the south-east corner of the wall, so as in future to effectually break the force of the wind at a period of the year when its effects are so hurtful to the young and tender foliage of these valuable exotic fruits.

It is usually advised that young Raspberry shoots should be thinned in summer in order to impart as much strength as possible to those which are left to bear the next year's crop. Another and most important effect of this thinning is to expose the selected canes to the ripening influence of sun and air, without which there is considerable risk of damage from an unkindly spring, as was clearly demonstrated in two beds this season. That which was thinned passed through the cold with impunity; but the other, which remained unthinned till autumn, had the wonderfully robust but unripened canes partly destroyed. I may add that these latter canes were of such exceptional strength that thinning appeared to be altogether unnecessary.—EDWARD LUCKHURST.

### GROSSE MIGNONNE PEACH.

This is one of the finest, if not the finest, full-sized mid-season Peach. It is only just second to Noblesse, which I deem the best of all Peaches. I had Grosse Mignonne originally under four different names, three of which were Padley's Early Purple, Royal Kensington, and smooth-leaved Royal George. The fruit is large, roundish, somewhat flattened and furrowed with a deep suture at the top which divides it into two lobes. Exposed to the sun it is of a fine crimson colour, sometimes brownish red; the skin is covered with soft down. The flesh is pale yellow, red under the skin on the sun side, and red at the stone. It is a rich, viscous, highly-flavoured

Peach. The stone is rough and small, the glands are round, and the flowers are large. The tree is said to be delicate and very liable to mildew; but I have seen nothing of either here. It is difficult to fix the season of ripening, but I suppose here it ripens usually from the third week in August to first week in September. My garden is cold and exposed.—W. F. RADCLIFFE.

### THE LATE CAMPAIGN.

Now that we are in the middle of August, and grouse shooting has commenced, we may consider that the Rose season is over. There may be good second blooms in a few gardens, but as Mr. Hole so well expresses it, these will be but the gleaming of the Grapes—the echo of the chorus. We can, then, now regard the late season with care, and deliberate upon its results.

That there have been some magnificent stands staged at the great Rose shows I am the first to own; but yet I do not hesitate to say that this has not been a good season for Roses. How, indeed, could it be? Never, for the last ten years at least, have we had such trying weather—a winter unusually prolonged, a most inclement spring, drought continued all through the most important month of May, followed by unusually cold weather during the early part of June. If under such circumstances as these we were able to have Roses equal to any of past years, then we might be able to snap our fingers at the weather, and say, Do your worst, you cannot hurt us. But no one, on the contrary, is so dependant on the weather as the rosarian, and for this reason: his plants must be grown in the open air; because, if not, the blooms will all be over before the Rose show season commences, and no amount of watering will compensate for continued drought during the growing season, while no plan of rough shelter can effectually withstand the severities of our English springs.

And yet in spite of all, some marvellous blooms have been staged at our great Rose shows. Mr. Cant of Colchester, the (I think this will be granted by all) premier exhibitor of the year, was never in better form, at least since I have had the privilege of seeing his Roses, while Mr. Turner has surpassed himself, and Mr. George Paul has been uniformly good throughout the season. Mr. Keynes and Mr. Cranston have most exposed nurseries. The former has also a very poor soil, while the latter is more dependant upon rain than any of his great rivals. What wonder, then, is it that this year they have not been more successful, since they have been martyrs to the ungenial season? Among amateurs Mr. Baker has well maintained his position. He was, I know, beaten for the head prize at the Crystal Palace, but he was first in every other class, and was also first for the chief prize at the Aquarium. A deluge of rain the day before the Alexandra prevented his showing, but in spite of this he has taken more first prizes throughout the year than any other amateur.

The surprise, however, of the year has been Mr. Nicholl of Bury St. Edmunds. I knew that we had a dark horse to contend with, who was expected by so great a judge as Mr. Cant to do great things, so I was quite prepared to hear of his success, and I am sure no one congratulates him more sincerely on his victory than do the leading amateurs. There is no envy, no bitterness felt by them; they like an open fair fight, and when defeated, so far from being angry, are the first to congratulate the victor, particularly if he is a new beginner. Mr. Jowitt of Hereford has been increasing his reputation; he won Mr. Cranston's challenge cup at Hereford, and has been grand all through the year, particularly with his pets the Teas.

And now as to individual Roses. This year has been a most extraordinary one. Some of the leading sorts, which are generally grand, have been nowhere. Particularly has this been the case with Charles Lefebvre, the grandest of Roses. I have never once seen this Rose shown well. It has been exceedingly light in colour, often small, and nearly always thin. Alfred Colomb, too, has been poor this year, and all the Roses of that shade of colour have been unsatisfactory. But on the other hand it has been a grand year for Reynolds Hole, Fisher Holmes, Louis Van Houtte, and Xavier Olibo. On the whole, however, I should say that this has been the year for light-coloured Roses. "The Baroness" and La France have been grand, Marie Cointet has maintained her position, and Eugénie Verdier has advanced.

Teas this year have been unusually good, in fact it was just the year to suit them, provided that due care was taken by

their owners in providing for their wants. *Souvenir d'Elise*, and *Souvenir d'un Ami*, and *Paul Neron* have been splendid, *Marie Van Houtte* and *Catherine Mermet* have never been so grand, while during the latter part of the season *La Boule d'Or*, that most difficult of all Teas, has been superb. I have not seen *Niphetos goodii*, or *Rubens*; but some of the most tender varieties, such as *Comtesse de Nadailac*, *Reine du Portugal*, *Mons. Furtado*, and *Cloth of Gold* have been very fine.

This is an honest expression of my own opinion, and the result of the most careful inspection of exhibitors' stands and of the blooms in my own garden and in those of friends; but I am quite open to conviction. The more we discuss Roses among ourselves the more we learn, and the more we love them. 'Tis like comparing vintages of Lafitte and Margaux, Haubron and Latour. We like them all, but we like to discriminate between them. We delight in recalling how such a season suited one variety and how utterly another failed. We like to compare notes and linger over the memory of our loves that are gone, and wonder if another year will restore them again, or give us new beauties to worship and old ones to revere in the memory of their past glories. But be the Roses old or young, be they vigorous growers or poor sickly plants that have to struggle to live, we love them all, and the memory of their beauty will console us through the long winter months; and the more we miss them the fonder will our hearts grow of the Rose, the queen of flowers, and our national emblem.—THE WYLD SAVAGE.

### AN INTERESTING GARDEN.

WHEN visiting Brambletye some months ago I was urged to call on Dr. Rogers at East Grinstead, being assured that I should find a garden worthy of inspection and an owner of it skilled in horticultural matters—a good collector, experimentalist, and cultivator of plants. Such I found was the case, and regretted that my time was so short, precluding me from doing more than glance through the place, and compelling me to forego the pleasure of entering into the history of the plants and trees growing in the houses and grounds. Dr. Rogers has been a great traveller and has added something to his garden from distant lands; hence almost every plant has a history, and is a living remembrancer of scenes and circumstances which had occurred it may be many years ago. The garden is only a small one, but is an instance that the pleasure which a garden affords is not to be estimated by its size, many small gardens affording great pleasure, and it is to be feared some large gardens contributing only a small share of enjoyment.

Dr. Rogers' garden is not an enclosure rendered gay by the employment of large numbers of popular bedding plants; indeed it has no pretensions to gaiety, and its contents are different to most gardens, its owner having endeavoured to establish and acclimatise tender plants and trees, some of which have survived many and severe winters. The Tea shrub (*Thea bohea*), for instance, has been growing and flowering on the lawn for upwards of twenty years, and during that time has not received the slightest protection. *Opuntia kaffiriana* is also firmly established, and is ornamental on the rocky knoll on which it has long been growing. This plant is, however, hardy, or would be if it was planted in many other gardens, and is one of the most distinct of plants for rockwork having a southern exposure. It is one of the very few species of Cacti that can be considered as hardy in our climate. The plant is of prostrate growth, the leaves being flat, fleshy, and spineless. The flowers are yellow, and are freely produced and succeeded by red pulpy fruits having a flavour somewhat similar to that of Gooseberries. In this garden the *Eugenia Ugni* is also growing without protection. *Saxifraga sarmen-tosa*, which is usually cultivated under glass, is rambling wildly amongst the stones of the rockery. *Azalea indica alba* has been growing as a hardy shrub for many years. *Arundo conspicua* has flourished for three years without receiving any injury. The *Eucalyptus globulus* grew for four years, forming quite a tree, but then succumbed to the severity of the weather. The wood which has been preserved is exceedingly hard. A healthy plant of the *Loquat*, *Eriobotrya japonica*, is trained to the walls of the residence, the large glossy foliage of the plant being highly ornamental. Bamboos (*Arundinaria falcata*) and many other tender plants are also growing freely in the open air in sheltered spots in the garden.

On the lawn are several fine shrubs, trees and Conifers. *Rhododendrons*, such as *Smithii*, *arborea*, &c., have attained

a great size, are in robust health, and flower profusely; and *R. Nobleanum* usually commences flowering in January. Standard Magnolias are very fine in the blossoming period—*M. conspicua*, and a kind with rosy flowers similar to but not so good as *M. Lenné*. There is also a good specimen of *Æsculus macrostachia*, and a fine tree of the seldom-seen *Pyrus vestita*, which flowers freely. There is a handsome specimen of the elegant Conifer *Fitzroya patagonica*, and *Aucubas* are yearly laden with berries without any artificial fertilisation of the flowers. Of *Wellingtonias* there are excellent specimens which have been raised from terminal cuttings by Dr. Rogers, and many other kinds of Conifers have been similarly raised, and are fully as free and handsome as are those which have been raised from seed. Of these may be named *Cupressus funebris*, *Picea Webbiana*, *Sequoia insignis* and *Cunninghamii*, and *Deodars*. There is also a plant of *Camphora* (*Camphora officinarum*), and a specimen of *Gleditschia* from the Coliseum at Rome.

The garden is on a considerable altitude, yet is well sheltered by close belts of trees and shrubs, and hence may be attributed the immunity from injury by frosts of several plants, trees, and shrubs which commonly need protection.

Entering the glass structures we also find the arrangement and management of the plants different to what we commonly meet with. The houses are small, one jutting against the other, convenience having been studied more than aspect. They contain no stages, but the plants are placed on or are growing in bold rugged knolls of stones and roots. The effect was good, the arrangement being as picturesque as it was possible to produce in the limited space. Some of the plants were very fine—specimens worthy of being exhibited. Notably so were *Agave coccinea*, *Dasyliroton longifolium*, *Dracæna indivisa*, *latifolia*, and *angustifolia*; *Ficus macrophylla*, *Alseodaphila australis*, *Cycas revoluta*, *Dicksonias*, &c. These plants, which have been growing under exceedingly cool treatment, are shortly to be disposed of on account of Dr. Rogers changing his residence, he considering that a successor could not be expected to take that care of them which they require to preserve them in their healthy state. Associated with these large plants are many Ferns growing luxuriantly in a semi-natural manner—*Aspleniums*, *Adiantums*, *Davallias*, &c. Most or all of the plants named are growing in an unheated house which has been many times below the freezing point, and yet the plants are sturdy and healthy.

Besides this and other houses there is a stove in which the most tender plants are preserved through the winter; but this is not kept at a stove temperature, a night temperature of 40° being considered sufficient, Dr. Rogers' object having been to inure his plants to the coolest treatment possible, and to this low temperature the plants after many years of preparation appear to have become acclimatised. Here Rice, Coffee, Cotton, and Sugar canes are grown together with *Caladiums*, *Begonias*, and *Orchids*. Of the latter plants there are some fine specimens, notably of *Cattleyas*, which produce their gorgeous flowers in great profusion, although the plants must many times have been within a few degrees of the freezing point.

Dr. Rogers has been an importer of Orchids, and was fortunate in introducing one with which his name has become identified—*Oncidium Rogersii*. This fine Orchid was observed by Dr. Hogg when on a visit to Dr. Rogers in 1868, and was recognised as not only new but extremely beautiful; it was consequently exhibited in London and arrested considerable attention. The following extract from a previous number of the *Journal of Horticulture* is well descriptive of a plant which is worthy of notice at the present time and of general cultivation:—

"Few species of the grand genus *Oncidium* have yet been met with of a more showy and ornamental character than *Oncidium varicosum* var. *Rogersii*. The flowers, indeed, are quite equal in size and beauty to those of *O. Marshallianum* and *O. pectorale*, while in brilliancy of colour they far surpass those of *O. macranthum*. The plant was introduced into this country by Dr. Rogers of East Grinstead, after whom it has been named; and was exhibited by him for the first time when just going out of flower in November, 1868. Both *O. varicosum* and the variety under notice are natives of Brazil, the latter differing from the former chiefly in the larger size of its flowers and in the fewer crests developed on the disk. It is one of the more ornamental of its race, and all the more valuable for its habit of flowering during the late autumnal months.

"The habit of the plant resembles that of *O. bifolium*. The pseudobulbs are of a long ovate form, and somewhat compressed

and ribbed; they support a pair of ligulate-lanceolate acute leaves, while from their base proceeds an ample branched nodding panicle of large yellow flowers. The sepals and petals are quite small, pale greenish-yellow, marked with brown bars. The lip is large, much crested at the base, where it is mottled with reddish-brown; it is furnished with rounded basal lobes, and has a large reniform middle lobe, which is upwards of 2 inches across, divided into four lobules, and of the purest and brightest yellow. The panicles attain about a couple of feet in length, are much branched, and bear sometimes as many as 170 flowers. Like *O. varicosum* itself, this is one of the finest *Oncids* we have in cultivation. In gardens it bears the name of *Oncidium Rogersii*, but Professor Reichenbach is no doubt quite correct in referring it to *O. varicosum*, the four-lobed front portion of the lip affording an unmistakable characteristic.

"Being a native of Brazil, it should be cultivated in the Cattleya house. It grows freely when suspended in a basket near the roof; and sphagnum, peat, and charcoal form a suitable compost for it."

This Orchid passed into the possession of Messrs. James Veitch & Sons, The Royal Exotic Nurseries, Chelsea, where it has since frequently flowered; it is also included in many private collections, where it is justly regarded as a valuable acquisition.

Dr. Rogers' garden is exceedingly enjoyable and instructive, and the owner possesses a thorough knowledge of plants that renders the visit of "one of the craft" peculiarly gratifying. The residence, which is a modern structure built from the owner's plans, purposely resembles an erection, both internally and externally, of the sixteenth century, and is quite in keeping with the somewhat quaint and unusual character of the garden and its surroundings.—J. W.

#### FLOWERS AND FRUIT AT SWANLEY.

PROBABLY at no period of the year is the country more really beautiful than when the ripening corn bends before the reaper and a bountiful harvest is being secured by the husbandman. The trees may then have lost their vernal freshness, but they are rich in their deeper hues of matured foliage. The pastures may be in a measure browned by the summer's sun, yet every spot of earth is bearing its fruits, and the landscape is diversified by the different tints which are not found at an earlier period. The golden corn and half-cleared field are brought into clear relief by the deep contrasting foliage of contiguous woods. The hills appear higher and the valleys deeper when the shadows of a declining sun are cast over a varied-tinted surface. Summer is the time of Nature's manhood. Woods, fields, and gardens are then in their prime; grain, roots, fruits, and flowers are alike being perfected, and the "aspect of Nature" is enjoyable and satisfying.

Fruits and flowers are now to be found almost everywhere, and a delightful landscape is afforded in many districts, but in few places are fruits and flowers so noticeable as at Swanley, and few districts contiguous to the metropolis are so attractive to the traveller as the richly clothed hills and the fertile valleys around. The views on the line of the London, Chatham, and Dover Railway are most varied and attractive. The villa residences are ornate and tasteful, and the flowers, glittering through the trees tell of homes that are cared for. The miles of fruit trees—plantations of fruit—the fields of Strawberries, of Hops, Potatoes, and corn combine to render the beauty of the landscape unusually complete.

In order to better appreciate this fertile district we alight from the train at Swanley Junction, and look more closely at the "flowers and fruit" to be found contiguous. Both are worthy of inspection. For a long time has this locality been famed for the extent and superior character of its fruit culture, but it is only recently that flowers have been added to its staple products—that is, since Mr. Cannell has laid the foundations of his plant manufactory. His expanding business having burst its limited bounds at Woolwich is now transported to a wider field, where an atmosphere undefiled by smoke is secured, a soil varied, fresh, and good is provided, where shelter is found without shade, and where rain water is collected from the surface instead of being raised from below it for the support of the plants.

The site of this new nursery has been skilfully selected, for it contains natural advantages of the greatest importance in carrying on the business which is already established. It may be instructive to record the nature of these advantages as a guide to others in the choice of a site for a similar object.

In the first place a position of some altitude was sought, for in such positions the frosts of spring are less destructive than in dells and valleys; and in the next place a hollow was desired for the collection of water from the higher ground. A hollow, therefore, at the top of a hill was the only site affording these conditions, and that is precisely the site which Mr. Cannell has obtained—a large hollow on the top of a high hill. A railway station must be near, and so near is Swanley Junction that the station overlooks the ground, and a siding on the railway is the boundary of a portion of the nursery. The high embankment of the Maidstone and Sevenoaks line is the south-western boundary of the nursery, and affords invaluable shelter; the opposite side being bounded by the London turnpike, and which also is turned to account in a manner worthy of being mentioned, and which is undoubtedly beneficial to Mr. Cannell and also to the district in which he has taken up his abode.

Between these two boundaries the nursery (long and narrow, and containing an area of 17 acres) is being laid out; its lowest part is the centre—that is, it slopes, as also does the adjacent road, from the ends to the middle. Down this road the surface water from the higher has poured in torrents, doing damage to the crops in the hollow. It occurred to Mr. Cannell that if he could preserve the winter's rains for summer use the water could not fail to be of great value. He therefore obtained permission to intercept the water, and forthwith laid down drains and grates, and formed two immense catch-water tanks, and connected these tanks with others in the different houses which he has erected. These tanks are all in connection with each other and furnished with valves. This complete system of water-storing cannot be too highly estimated. It includes the drainings of manure from farms and from the railway station. The work cannot fail to have been costly, yet in the end will be found most economical, for the only force requisite to provide a supply is the costless force of gravitation, and the water is of course vastly superior to that pumped from springs. Already tanks are made holding 150,000 gallons, and further tanks will be added as other houses are erected. The tanks are built of 4-inch brickwork lined with cement, and the pipes connecting them together are also jointed with cement. The water from about two acres of road surface already drains into the tanks. It was a happy conception and has been admirably carried out. There are doubtless other places, both trade establishments and private residences, so situated that the same mode of collecting waste surface water in the rainy season might be carried out with the greatest advantage; for a sufficient supply of soft water is a store of wealth to all gardeners and cultivators of plants.

After making due provision for a full supply of soft water by conserving the surplus rainfall of the district, the next important matter was the one of shelter. This is of the greatest advantage in both nurseries and private gardens. If the frosts of spring can be in a useful measure averted and the destructive effects of the frosts of autumn be in any way postponed, also if the force of the winds at all seasons be broken, a substantial gain is attained. In many of the Belgian nurseries the value of sheltering lines of shrubs and trees are fully recognised, and hedges of Lombardy Poplars and evergreens intersect the ground at frequent intervals, forming enclosures having a higher mean temperature by several degrees than where such sheltering lines are not provided. In many English nurseries the importance of shelter is similarly appreciated, but not generally to so great an extent as on the Continent. Mr. Cannell is fully alive to the value of shelter, and is planting lines of Lombardy Poplars to be trimmed into close hedges to afford shelter, also shade, without the overhanging branches, where such aids are needed. These Poplars form the quickest, cheapest, and most compact of hedges for the internal subdivision of nurseries and gardens. In the nursery at Swanley they are employed freely, and it is a question whether even a more extended use of them would not prove advantageous.

Besides the lines of Poplars, subsidiary divisional lines are being formed of Vines. Mr. Cannell has an idea that a plant of so hardy a nature as the Vine is as often injured as benefited by its increase from eyes and its cultivation in pots. He is therefore adopting a simpler, cheaper, and harder mode of culture, and intends raising stout hardy canes for transplanting by growing them in the open ground and air of his nursery. Between these rows of Vines are plantations of flowers. For instance: six plants of a sort of nearly four hundred varieties of *Chrysanthemums* are planted out for "stock," and to keep them "true to name." Thus sheltered

by the Vines the plants will not need the support of sticks, and a saving of both labour and material is thereby effected.

Other kinds of plants are planted on the same extensive scale. Antirrhinums, Phloxes—a great collection—Pinks, Dianthus, Succulents, Campanulas, Wallflowers, and other hardy flowers; also tender plants, as Geraniums, Pentstemons, Lantanas, Lobelias—in fact, flowers of all kinds and the newest varieties of each are submitted for trial and for increase in the system of flower beds which are formed and in the course of formation.

Already some flowers in these beds attract notice by their distinctness or superiority. The Malshanger seedling Antirrhinum is an effective novelty, the flowers being not only double but are freely produced. Another variety, A. Hendersonii, rose and white, is one of the most constant and striking of all the striped sorts. A double Sweetwilliam rivals in colour and almost intensity a Cockcomb. A new Lobelia surpasses in richness of colour the rich *L. pumila magnifica* and Blue Stone. Lantanas are extremely effective, the hot season having suited them. So, also, are the Veronicas, notably *V. imperialis*, and especially the rich purple variety *Mdlle. Claudine Willermoz*. This cannot fail to be a fine summer-flowering conservatory and garden plant of the easiest culture. *Sedum spectabile* is bedded out, and with it the newer and taller variety *S. japonicum*. When these plants are cultivated instead of being starved, as we so often find them, their gigantic rosy-pink heads are exceedingly attractive. Pansies are grown in large numbers, but the great heat and drought has limited their beauty. *Viola Queen Victoria* is one which has endured the best. It is a rich and fine variety, and equally valuable is the *Tory*. A new strain of Pentstemons is being established, the plants being altogether more dwarf and sturdy in habit than those of the ordinary type, the flowers of the dwarfs are also equally superior. The new strain is likely to prove a valuable addition to an attractive family of plants.

Geraniums are extensively planted, but the extreme heat has caused many of them to produce trusses of seed. Two Geraniums thus planted are particularly worthy of notice—namely, the new double Ivy-leaved variety *Konig Albert*, and the new bedding zonal *Jealousy*. *Konig Albert* as bedded out is compact in growth with foliage of the brightest green, and the flower trusses are supported clearly above it. These are produced in great profusion, and the fine double flowers are striking by their massiveness and are attractive by their soft lively colour. A great advantage of this variety is that the decaying flowers shrivel and drop off instead of adhering to the trusses, as do the flowers of many double varieties, looking dismal and unsightly. That the first double Ivy-leaved Geranium should be so free and so useful is almost more than could have been expected. It combines all the good qualities which render a plant popular, and cannot fail to be largely grown.

*Jealousy* must also become a general favourite in the flower garden, and it is also fine for cultivation in pots, but it is as a bedder that it is the most valuable. Whether the novel name was given in consequence of yellow being emblematical of jealousy, or whether the possession of this variety would provoke feelings of jealousy in the minds of others not possessing it, Mr. Cannell does not enlighten us; but certain it is that it is one of the best and most distinct bedders of the day—a variety to be coveted, and certain also is it that it contains more yellow in its petals than does any other Geranium. A small individual plant does not adequately show its merits, but to see plants blooming in large numbers the play of yellow over the mass is very decided and pleasing. It is dwarf yet of free growth, and the pips are of good shape. It flowers apparently as profusely as does *Vesuvius*, and like that well-known variety is likely to become a staple Geranium for flower-garden purposes.

A little must be said of the glass structures and their contents. A considerable extent of glass is projected, and some span-roofed houses—a total length of about 500 feet—are already erected. These are compactly and conveniently arranged; they are light, durable, and well ventilated, and are admirably adapted for the increase and cultivation of plants. The lower portions of the lights and rafters—indeed, every part of the woodwork near the gutters and floor—has been twice dipped in tar. The gutters between the houses are made with cement, and conduct the water to the tanks above mentioned. The houses are glazed with stout English glass, bedded in putty and fastened with springs, no putty being used above the glass. "Circulators" are in the course of being

fixed to supply the heat, the water being conveyed by a 3-inch pipe along the floor of the house, returning by three pipes each an inch in diameter, and affixed to the roof above the plants—that is, three pipes are employed along each roof, or six pipes to each house. Were not this great innovation in heating by hot-water something more than a novel idea Mr. Cannell could not have afforded to have adopted it on such an extensive scale as is here projected and being carried out. After much experience and careful testing and comparison he has adopted it as the most economical and best suited to his purpose. A number of low pits or frames are heated in the same way—that is, the heat is conveyed from above the same as is heat from the sun, and also on the principle that as cold in winter "comes in" by the lights—really heat escaping, it is at the lights that the heat is provided, being the place where it is most needed, and where it is the most effectual in preserving the plants from frost and damp. This topsy-turvy system of heating is in opposition to the orthodox notions of hot-water engineers, but it answered its purpose for several years at Woolwich, and there is no suspicion of any lack of confidence in the mind of its introducer that it will not answer equally well on an extended scale at Swanley.

Only very briefly can the contents of the houses be alluded to. One house is filled with Geraniums—the newest and best varieties extant—the cream of English and continental raisers. The great variety of colour and the enormous trusses produce a remarkable display. Some of the newer double varieties are a great advance on the older kinds, the plants possessing the same short-jointed growth and freedom of flowering which is common to the single varieties. Almost every shade of colour is found in these varieties, from the pure white of *Mdlle. Amelie Baltet* to the rich magenta of *M. Buchner*. A few selected from this fine collection—the cream of the cream—may be relied on as highly superior. Little more can be done than to give their names, the particulars of them being truthfully detailed in Mr. Cannell's "Floral Guide." Twelve splendid doubles are the following:—*Mdlle. Amelie Baltet* (pure), and *Lucy Lemoine* (blush), whites; *Jewel* and *Meteor Flag*, scarlets; *Madame Dauphin* and *Madame Boutard*, rose-coloured; *Madame Thibaut* and *Engène Bandowin*, pink, suffused with purple; *J. C. Rodbard* and *Henri Beurrier*, salmon-tinted; and *C. H. Wagner* and *M. Buchner*, crimson, suffused violet. That is a very select list, to be converted into a baker's dozen by the addition of Mr. G. Smith's semi-double variety *Wonderful*, a variety which should be possessed by everybody. It is a sport from *Vesuvius*, and has all the good qualities of the parent, but is more brilliant and semi-double. It will prove splendid both for pots and beds; and it is probable that others of the new race of doubles will also prove good bedders. The old varieties of doubles afford no idea of the merits of the "later introductions." A few of the most striking of the single Zonals were *Lemoine's Drapau*, *Tricolor* and *Deputé Valentine*; *Dr. Denny's Astarte* and *Salathiel*; *Mr. Pearson's E. G. Henderson*, *Lord Zetland*, *Havelock*, *Louisa*, *Mrs. Lancaster*, *Mrs. Gregory*, *Ethel*, *T. F. Fenn*, *Lady Byron*, *Lucy Bosworth*, *John Gibbons*, and *Sir H. Stanhope*. *Apple Blossom* (Cannell), *Mrs. George Gordon* (De Vere), *Remus* (Postans), *Sir P. Dyke* (Borrowdale), *Marguerite Ponton* (Bertrand), *Seraph* and *Ivanhoe* (George), *Mrs. G. Smith* and *Dreadnought* (Smith), and *Vanessa* (Miles). *White Clipper* remains the best of its section. Those are a few of the very best of this fine collection.

Another house is occupied with Fuchsias—healthy, handsome plants of the choicest varieties. Fuchsias are indispensable for the summer decoration of conservatories. Mr. Cannell's plan is to grow the plants quickly, permitting them to receive no checks, affording them abundant ventilation and very slight shade. Where all are so good it is difficult to eliminate "the best;" a few, however, may be found which are especially noticeable. One of the most striking is *Aurora Superba* as being the first step towards a yellow variety. The plant is vigorous and the flowers are fine; the tube and sepals being salmon and the corolla orange scarlet. *Ethel* (Bull) is remarkable by the great length of its pure white tube; and *Fireworks* is distinct by its profusion of pendulous brilliant buds. *Champion of the World* is still the largest double dark variety, and a white companion is found for it in *Miss Lucy Finnis* (Simmonds), which is profusely weighted with its enormous flowers. The best double white, however, taking all its qualities into consideration, is *Mrs. H. Cannell*. *Little Alice* is also most lovely; and *Sir G. Wolseley*, *General Chanzy*, and *Avalanche* are the best double darks. Of single varieties with light tubes and dark corollas *White*

Souvenir de Chiswick and Covent Garden White are two of the freest and finest for decorative purposes. Guiding Star, Rose of Denmark, and Lucy Mills are also as effective as ever. The best singles having white corollas are Mrs. E. Bennett and Delight. Of dark singles Lord Falmouth is a grand new variety, and highly superior are T. T. Lowden, Model, Crown Prince of Prussia, Enoch Arden, Gazelle, Father Ignatius, Try-me-Oh, Swanley Gem, Dr. Kitto, Giddings, Roderic Dhu, Noblesse, First of the Day, and Day Dream. A distinct self-coloured variety is Sedan. Erecta von Novelty is an erect and most profuse-flowering variety, attractive for pots and likely to be particularly effective when planted out.

Another house is nearly filled with Petunias, principally single-flowered varieties, which have been raised from seed. This collection is remarkable for the extremely varied colours of the flowers, their high quality, rich markings, and delightful perfume. Many plants possess the bold rigid habits of the doubles. Some of the single flowers are from 2 to 3 inches in diameter, and have large reticulated trumpet-shaped tubes; others are small, perfectly shaped, and chastely marked. Their colours range from white to magenta. Some of the varieties are to be named. It is the finest strain of single Petunias that has probably ever been produced.

It is interesting and also instructive to note the successful way by which Mr. Cannell raises his supply of Primulas, Cinerarias, and Calceolarias. This is an important branch of his business, and hundreds of thousands of these seedlings are now growing in seed boxes in low frames. The seed is sown on thoroughly moistened soil and the boxes are then placed in frames, which are thickly covered with mats and kept dark. That is all that is done or required, no soil or sand being sprinkled over the seed, and 95 per cent. of good seed will germinate. It is exceedingly simple, but only a moment's reflection is needed to convince one that it is the right plan to adopt. By this mode the soil needs no watering until after the seedlings appear. The mats are gradually removed when the plants appear, and during fine nights the "crop" is exposed to the refreshing influence of night air and dews, and the plants grow freely and vigorously.

After writing so fully of the flowers only a little can be said of the fruit at Swanley. The season's crop is now gathered, but an idea may be given of the extent of its cultivation. On the "farm" adjoining the nursery a ton of Raspberries have this year been gathered before breakfast, and 11 tons of Strawberries have been sent to market by the same proprietor, Mr. Vincent. The total weight of Strawberries which have this year been gathered in the district is 80 tons. They were sent to London in vans, and to Manchester and the north in railway trucks. Five pence per peck is paid for picking them, the fruit-pickers coming principally from London, and "gipseying" in the locality. After "fruiting" is over they commence "hopping," and after the Hops are gathered they commence "tating"—taking-up and storing Potatoes. The manner in which the fruit and Potatoes are grown may be alluded to in another communication.

The district is evidently particularly suitable to the cultivation of "flowers and fruit," and is also exceedingly salubrious and conducive to the health of its inhabitants, for not only does Swanley contain superior examples of vegetation, but also, no doubt, the most wonderful specimen of humanity to be found in Her Majesty's dominions, or probably in the world. As the Brobdingnagian Boy of Swanley has not yet been honoured with public notice, perhaps he may be alluded to here. His name is Richard Beenham, he will be twelve years of age on the 31st of the present month, his height is 5 feet, his girth round the waist is 69 inches, and his weight upwards of 24 stones of 14 lbs. to the stone. He is healthy and in possession of his faculties. His father is a basket-maker, and the "boy" appears to be learning the business.—J.

#### DRILLING CABBAGE SEED.

THE common culture of this plant, as everyone knows, is that of sowing the seed on a seed bed, and transplanting the plants where they are to remain to produce Cabbages. The drilling system precludes the necessity of transplanting, which in a season like the present can only be performed during or immediately after rain, and in case of a drought must be postponed often for a long period. I have often remarked how

superior plants have been that were singled-out in seed beds and left without moving when compared with others which had been transplanted. Last July I drilled some Walcheren Broccoli with great success. I sow the seed thinly in quarters where the plants are to remain. Thinning must be attended to early and in a gradual manner, so that in case of any of the plants being destroyed there may be no blanks in the rows. I should be glad if some of the readers of your Journal would give us their opinion on the drilling system in gardens. —WILLIAM GILES.

#### IMPROVED WATER BARROW.

THIS water barrow for garden purposes, to which is attached a patent rotary pump, is manufactured by Messrs. Barnard and Co., Norwich. It is very simple in construction, and

Fig. 16.

efficient in action. The pump can be worked by a boy, and is capable of throwing a continuous stream of water to a distance of 40 feet or 50 feet. If treated with care (as any piece of good machinery should be) it will last for many years. These pumps should be well oiled after use, and when the jet pipe is removed a cork should be placed in the aperture of the pump.

#### THE TIMBER SUPPLY OF THE UNITED STATES.

A PAMPHLET we have received on the "Timber Supply of the Dominion of Canada and the United States of America," by Mr. James Little, reveals a state of consumption and waste of timber that must make our political economists and those interested in this great source of wealth reflect a little on the consequences. Twenty-five millions of dollars are received yearly from the forests. Mr. Little shows in his pamphlet that great waste is going on, that the Governments of Ontario and Quebec through their Crown Timber Office (generally under the control of lawyers quite ignorant of the duties), have been hastening the stripping of the country of its invaluable timber resources, which never can be reproduced, so far as the white Pine is concerned, by throwing them on the market without reference to the requirements of the trade—their object being to see which of them can raise the largest revenue and make the best exhibit in their budget speeches, regardless of the resources of the country. Mr. Little shows, by figures carefully obtained, that the effect of this waste will be, at the rate of consumption going on, that there will not be a tree left, a dozen years hence, on this side of the Rocky Mountains, of the commercial woods which yield such large returns and supply home purposes. The census of 1870 showed a production of sawed timber of 12,755,543,000 feet, and the addition of timber made into shingles and hewn, flattened and rounded timber used at home and exported (excluding firewood), reaches the enormous amount of 20,000,000,000 feet, or 30,000,000 of tons, from which Mr. Little estimates it would require more than 50 per cent. more than the shipping of the whole world to freight that quantity from their Pacific states and terri-

ories to the Atlantic seaboard, besides distribution or cost of carriage to points of consumption. The State of Maine—known as the Pine-tree State of the Union—has its forests all but stripped of that wood, and the work of cutting up the Spruce out of logs 6 to 8 inches in diameter, to glut its own and the English market, is being carried on by the mills. Statisticians calculate that the constant drain will exhaust the State within five years. It appears that other eastern States, New Hampshire, Massachusetts, Connecticut, Rhode Island, and the States of New York, Delaware, Maryland, Ohio, &c., at one time dense forests of the finest Pine timber, are denuded of that product, and have little timber left. All kinds of rubbish are being sawed up, patches of firewood are being thinned, and these States are large purchasers of Michigan and Canada Pine and Spruce timber to supplement their own valueless home product. Even firewood has almost disappeared. It is stated that Pennsylvania, one of the best Pine-producing States of the Union as regards the quality and extent of its timber, is within a few years of its exhaustion.

A recent writer on the subject says consumers are awakening to a knowledge of the important fact that the Pine resources of Pennsylvania are not inexhaustible. The dense forests bordering the Susquehanna, the mountains of the Monongahela Valley, and the majestic trees which covered thickly a few years ago the whole area, and appeared sufficient to supply the demands of a future however distant, now show signs of speedy exhaustion. Some of these States are only just beginning to be awakened to the truth, and are earnestly considering means to stop the reckless management and waste which has been going on for years. Pine-lumbering is one of the finest industries of Pennsylvania, and every suggestion to check the impending loss must be considered. Even the coal regions cannot supply enough timber to furnish the necessary props, though once famed for their Pine. It is declared by the same writer that four years "will exhaust the supply of the Susquehanna Valley, and the now comparatively neglected Hemlock will become the staple of the timber trade of that section, as it has been for years in the Delaware region."

To give an instance of the exhausting process going on, it may be stated the State of Pennsylvania manufactured and consumed, according to the last census, 1,610,000,000 of feet, about 500,000,000 of which were Pine, the remainder being Hemlock, and this vast amount is three times as much as is shipped from Quebec of both deals and timber, if the latter were sawn into boards. Virginia, Carolina, Mississippi, Tennessee, Kentucky, &c., have Pitch Pine and Cypress, which cannot take the place of White Pine. This is being destroyed by turpentine farmers at the rate of 10 per cent. per annum. The wood is found to decay rapidly in buildings when in contact with mortar; hence the low estimate of this timber in the English market.

We need not give more instances of the wholesale slaughtering of these once magnificent Pine forests, and we may inquire in passing, What the effects are likely to be of this devastating and sweeping operation? Commercially, the States must suffer—a great source of wealth is being sacrificed with recklessness; and, physically, we can scarcely estimate the consequence of this vast destruction of forests in altering the balance of natural laws. The author shows, by statistical returns of industries in which wood plays a great part—as carriages, furniture, bridges, ships, railway sleepers, fences, telegraph poles, &c.—what must be looked for when the supplies of these great industries are cut off. All the commercial convulsions and monetary crises that have ever happened will be nothing compared to the calamity occasioned by a dearth of timber. Yet, in ignorance of this, the lumbermen keep slashing away, and appear to be hastening on the crisis, as if their business was to extirpate this source of industry. The same complaint is made of the Valley of the Ottawa, Nova Scotia, and other States. Lumbermen are now recklessly throwing away what in five years' time would be worth £5000 an acre. It is stated that in five years neither Pine timber, nor deals, nor Spruce will be shipped from Quebec, and timber will be higher on that side of the Atlantic than this.

The writer in conclusion suggests a remedy which Ontario at once, and Quebec in two years' time, can do; and that is, to stop the getting-out of square timber in the woods, which occasions the loss of one quarter of the most valuable part of the tree, and the greater destruction of cutting down trees to make into timber, but which, from some imperfection, is found unsuited, and is allowed to rot in the woods, although much would be valuable for saw logs. Fire is also a source of

great destruction in forests, which follows the getting-out of square timber, as the least spark in dry weather ignites the hewings, and sets the forest ablaze. The only remedy for all this waste is to stop the making of square timber for exportation.—(*English Mechanic*.)

[This suggests that not only in America, but in Europe, planting of timber trees should be encouraged. Admiral Collingwood used to have a supply of acorns in his pocket, made a hole with his stick, and dropped one in wherever he thought the young Oak would prosper.]

#### NATIONAL CARNATION AND PICOTEE SOCIETY.

THE Exhibition for this year was held in the Botanical Gardens, Stretford, Manchester, on the 11th and 12th inst., and florists from the midland counties, from the north, and from the south met together in great numbers, most of them bringing flowers with them; some, like Messrs. Simonite, Bowers, Rudd, Booth, and others staging nearly a hundred flowers each. We cannot say that the arrangements were perfect. In the first place, the members were called together by the Secretary when the flowers were staged, and the Judges were selected from amongst them by vote; and certainly some of them were not adequate to the position allotted to them. In the next place, the conservatory ought to have been cleared of all the exhibitors before the judging commenced, and no one ought to have been admitted until the awards had been declared. It is bad enough for Judges to face disappointed exhibitors after their labours are finished, but to be surrounded with them while their work is going on ought not to be allowed. Perhaps it was owing to this that several mistakes were made. And here it may be as well to remark on the critical acumen of the Judges. In the principal class for Carnations in twelve distinct sorts, a pan sent by Mr. G. Rudd of very fine flowers (indeed the premier flower in the Exhibition was found in his stand) was disqualified from having a splendid flower of Sarah Payne (Ward), one or other of the petals of which was wanting in bizarre, but on carefully looking over the petals not one could be found that had not any spot or bar of the purple. The same exhibitor was also disqualified in the principal Picotee class by having two light red-edged flowers in it so nearly alike that the Judges could not distinguish them. One was Thomas Williams and the other Rev. F. D. Horner. These two decisions were ultimately altered by the managers of the Show, but not until 6 p.m. of the day of exhibition, and fourth prizes were awarded in each class.

The Show was a very good one. Most of the flowers, though not very large, were remarkably clean and fresh, but they did not stand very well, as the two days were very hot and the glass roof of the building was not sufficiently shaded. This was a misfortune in another sense, as the beautiful markings are best brought out in a subdued light.

The following are the awards of the Judges:—Twelve Carnations (distinct), Mr. Jonathan Booth, Pole Lane, Failsforth, Manchester, was first with Garibaldi, Jas. Merryweather, Ivanhoe, Admiral Curzon, Earl of Wilton, Sir J. Paxton, John Keet, Annihilator, Lovely Ann, Juno, Sportsman, and Lord Milton. Second, Thomas Bowers, Esq., Dirkhill, Bradford, with Admiral Curzon, a grand flower; Sportsman, Squire Meynell, John Rich, Clipper, a new scarlet flake of fine quality; Eccentric Jack, E. S. Dodwell, Sir J. Paxton, Mars, Lord Raglan, John Bailey, and Mayor of Nottingham. Third, Mr. Benjamin Simonite, Rough Bank, Sheffield, with Frank Simonite, Mr. Findlay, F. D. Horner, John Simonite, Jas. Douglas, Samuel Barlow, Sportsman, Earl Stamford, Admiral Curzon, and Hector. Richard Gorton, Esq., Gilderbrook, Eccles near Manchester, was fourth with a stand of very bright flowers; amongst them Mercury, Jas. Cheatham, very fine; Warrior, and Rose of Stapleford. An equal fourth was given to Geo. Rudd, Esq., Undercliffe, Bradford, for his disqualified stand; and Mr. Joseph Chadwick, Ashton-under-Lyne, was fifth.

In the class for twelve Picotees, distinct, there was also very close competition, and it contained some very fine flowers. Mr. Booth, whose flowers were just in at the right time, was again first with Mrs. Summers, Mrs. May, Morning Star, William Summers, J. B. Bryant, Mary, very fine; Countess of Wilton, Miss Wood, Cynthia, Scarlet Queen, Ann Lord, and Edith Dombrain; this last sort has been very fine in the north this year. Mr. Simonite was second with J. B. Bryant, Mrs. Douglas, Jenny Ibbison, Mrs. Gorton, Mrs. Summers, Mrs. F. D. Horner (in memoriam), Silvia, and unnamed seedlings; except J. B. Bryant this stand was composed entirely of Mr. Simonite's own seedlings. Robert Lord, Esq., Todmorden, was third. In his stand were good flowers of Miss Horner, Ann Lord, Minnie, Alice, and Miss Small. Messrs. Bower & Rudd were placed equal fourth.

The next class for twelve Carnations in nine distinct sorts Mr. Booth was again first. In this stand were Uncle Tom, Lord Napier, True Briton, &c. Second came Mr. Simonite with J. D. Hextall, Desdemona, Othello, and seedlings. Third, G.

Rudd, Esq.; in this stand Sarah Payne, Clipper, and Falcon-bridge were fine. Mr. John Beswick, Middleton, was fourth, and Richard Gorton, Esq., fifth. In this stand were fine blooms of Graceless Tom and James Cheetham, and the best Sarah Payne in the Exhibition.

In the corresponding class for Picotees Mr. Booth won the first place with very fine flowers, Miss Lee, Mrs. Dodwell, Nymph, and Mrs. Lord being especially superior. Mr. Simonite was second with Mrs. Niven, J. B. Bryant, Mrs. Summers, and seedlings. Third, Mr. Beswick. This stand contained amongst others Bonny Jane, Beauty of Plumstead, Ann Lord, and Mr. Harland. R. Gorton, Esq., was fourth with John Smith, a fine flower; Nymph, and Mrs. Booth. G. Rudd, Esq., was fifth.

For six distinct Carnations Robert Lord, Esq., was first with John Keet, Juno, Sportsman, Lord Raglan, Admiral Curzon, and Clipper. Mr. Booth second; Mr. Rudd, Mr. Simonite, and Mr. Chadwick taking the remaining prizes in the order named.

For six distinct Picotees Mr. Simonite was first with Mrs. Summers, Mrs. Simonite, Teresa, J. B. Bryant, and a seedling. Mr. Booth; R. Gorton, Esq.; S. Cooper, Esq., Timperley, Cheshire, and Mr. Chadwick being the remaining prizewinners.

The prizes for the best single blooms brought out a large competition, some of the growers showing at least a dozen blooms in each of the classes.

#### CARNATIONS.

*Scarlet Bizarres*.—1, R. Lord with Admiral Curzon. 2 and 3, J. Booth with Admiral Curzon and Admiral Napier. 4, — Simonite with a seedling. 5, T. Bowers with Sir Joseph Paxton.

*Crimson Bizarres*.—1, 3, 4, and 6, — Simonite with John Simonite, Eccentric Jack, and Samuel Barlow. 2, S. Cooper with Rifleman. 5, J. Booth with Lord Raglan.

*Rose Flakes*.—1 and 2, R. Lord with Sportsman. 3, — Simonite with Rev. F. D. Horner. 4, — Beswick with Clipper. 5, J. Booth with Wm. Harland. 6, T. Bowers with Clipper.

*Rose Flakes*.—1 and 2, R. Lord with John Keet and a seedling. 3, T. Bowers with E. T. Dodwell. 4 and 6, J. Booth with James Merryweather and Lovely Ann. 5, — Whitaker with Crista-galli.

*Purple Flakes*.—1 and 4, R. Lord with Juno. 2, T. Bowers with Squire Meynell. 3, — Simonite with James Douglas. 5, J. Booth with Lady Peel. 6, — Beswick with Earl of Wilton.

#### PICOTEEES.

*Heavy-edged Red*.—1 and 2, T. Bowers with J. B. Bryant and Mrs. Dodwell. 3, — Beswick with a seedling. 4, R. Lord with John Smith. 5, S. Cooper with Miss Small. 6, J. Booth with Brunette.

*Light Red-edged*.—1, 2, 3, 4, 6, — Simonite with Mrs. Gorton and four seedlings. 5, T. Bowers with William Summers.

*Heavy Purple-edged*.—1 and 2, R. Gorton with Mrs. Summers and Norfolk Beauty. 3 and 4, — Simonite with seedlings. 5, — Beswick with Mrs. Summers. 6, J. Booth with Alliance.

*Light Purple-edged*.—1, — Beswick with Mary. 2, R. Gorton with Mary. 3, S. Cooper with Ann Lord. 4 and 6, R. Lord with Alice and a seedling. 5, Simonite with a seedling.

*Heavy Rose-edge*.—1 and 4, R. Lord with Miss Horner. 2 and 3, J. Booth with Mrs. Lord. 5, — Mellor with Edith Dombrain. 6, — Beswick with Bonny Jane.

*Light Rose-edge*.—1, R. Lord with Miss Wood. 2, J. Booth with Miss Wood. 3 and 6, T. Bowers with Ethel. 4, — Beswick with Miss Nicholls. 5, — Mellor with Bertha.

Flowers to which first-class certificates were awarded:—

**CARNATIONS.**—*Scarlet Bizarre*: Ohello, a very distinct flower with rich markings. It is the darkest flower that has yet been seen, with a broad stout petal and a smooth outline. *Crimson Bizarres*: Samuel Barlow, a very beautiful flower of the largest size, and in the formation resembles Isaac Wilkinson, with colours brighter and more defined and better petals. Frank Simonite.—This is quite distinct, and a grand flower of large size and immense breadth and smoothness of petal, markings very regular. John Simonite, a seedling from Jenny Lind (Puxley), very large and a most striking flower; white, very pure. *Purple-flake*: James Douglas is, perhaps, a seedling from Mayor of Nottingham, but it is much superior to that sort; the white is very pure, the flakes regular and well defined; petals broad, stout in substance, and quite smooth. *Scarlet-flake*: Rev. F. D. Horner.—This sort stands very high in its class; it is certainly the most constant, and has the smoothest petal, the markings very regular. Colour bright scarlet.

**PICOTEEES.**—The following varieties like the above have been raised by Mr. Benjamin Simonite, Rough Bank, Sheffield, and amongst them will be found some of the finest and best-marked flowers in existence, and when they are grown under better circumstances they may be expected to be seen in still better form. *Light Red-edges*: Mrs. Simonite. This gained the premium prize as the best Picotee in the Exhibition. It is certainly grand, petals smooth, shell-like, pearly white, with fine wire edge. Mrs. F. D. Horner is best described as a red-edged Mary, and will hold a high position in years to come. Mrs. Gorton, fine smooth petal without spot or bar, and wire edge. Mrs. Douglas, one of the most distinct flowers exhibited. It is a lovely flower with smooth petals and well-defined medium mauve-purple edge. Silvia, a chaste and elegant flower with the finest purple wire edge yet seen. Similar awards were also given to Rose-flake Carnation E. S. Dodwell (Bower). It has brilliant cherry-rose flakes, and very neat. Mrs. Dodwell (Lord), another Rose-flake of good substance, and bright deep rose flakes regularly disposed, smooth petal. Miss Horner (Lord), a

very fine, heavy, rose-edge, lighter in colour than Edith Dombrain, and a better flower.

Perhaps an equal number of first-class certificates has never been awarded in one day for these florists' flowers.

As a supplement to the Carnation Show, collections of fruit and flowers were sent by various exhibitors. The Society's silver medal was given to Mr. J. T. Rayner, gardener to E. Molyneux, Esq., Rock Park, Birkenhead, for two splendid bunches of well-finished Black Hamburgh Grapes; their united weight was 11 lbs. 10 ozs.

First-class cultural commendations were also given to Mr. W. Leech, Fallowfield, near Manchester, for a good *Saccolabium Blumei majus*; to S. Cooper, Esq., for *Adiantum farleyense*; to Mr. John Rylands for black and white Grapes; and a first-class certificate was awarded to Mr. Hill, gardener, Keele Hall, for a new white-fleshed Melon.

The following had first-class commendations:—Mr. Upjohn, gardener to the Earl of Ellesmere for a collection of fruit in twelve distinct sorts; it comprised Black Hamburgh and Duke of Buccleuch Grapes, the latter with immense berries, Pines, Peaches, and Nectarines, and a Melon; the collection was well set up. Messrs. G. & W. Yates for bouquets; and Mr. Leech for *Oncidium macranthum*.

## TAUNTON DEANE HORTICULTURAL SOCIETY.

AUGUST 10TH.

THE Royal Agricultural Society of England held their Show at Taunton last year, and hence the great annual gathering in connection with the Horticultural Society was omitted, so that it was two years since I had the pleasure of visiting this most charming Somersetshire town. During that time of course changes had taken place; a new Secretary had been appointed, but in many respects there had been no change. There was the same gala-day appearance about the town; bunting was largely displayed; the streets were crowded, not only with the carriages of the neighbouring gentry but by holiday-keepers of all sorts; while in the Vivary Park, where the Exhibition was held, there was to be seen the same array of tents filled with the productions of most of the old and many new exhibitors. The same genial reception was given to all who were partakers in the arrangements. Judges and officers of the Society, and leading exhibitors met together to talk over horticulture and to give and receive hints on the subjects of deepest interest to them.

The extremely dry and scorching weather that we have lately experienced had its effect upon the cut flowers, and together with the utter carelessness of the railway people tended somewhat to mar the Show. The plants of the Messrs. Drummond never left Bath, as the Great Western Railway had no trucks to take them; while of the eight boxes of cut Roses brought by Mr. Prince, and which were deposited safely at nine o'clock the night before at the Taunton station, only two could be put up, the others having been turned completely over, and shavings, moss, tubes, and Roses all mixed together. It must have been the result of thorough carelessness. Then, unfortunately, there is no redress; and indeed when one sees what has happened on these southern lines lately I suppose Mr. Prince would be told that it was fortunate it was only his boxes and not himself that came to grief. But notwithstanding these drawbacks the Show was a most excellent one, the two collections of stove and greenhouse plants exhibited by Mr. Cypher of Cheltenham, and Messrs. Lacombe, Pince, & Co. of Exeter, being probably as fine collections as ever were exhibited in the month of August. The Heaths in the former collection were superb specimens of culture. Ferns also were contributed by the same exhibitors and by Messrs. Bryant & Co. of Bath in fine order, including good specimens of *Adiantum farleyense*. There were also some fine Palms and excellent specimens of Lycopods. Mr. Williams of Holloway sent a large number of new and rare plants not for competition; and the large number of zonal Pelargoniums contributed to the gaiety of this tent, which formed the principal point of attraction. But surely I may suggest to the promoters of the Show that it is time to discard the classes for tricolor and bronze Pelargoniums. August is much too late for them, and the fancy for them has so completely altered that no one would regret to see other classes substituted for them. It is impossible at this season to distinguish varieties, and if an exhibitor chose to put up three or four of a sort it would be very difficult to distinguish them.

The amateurs' classes were not quite so well filled as I have seen them, but here again the weather has been unpropitious. Amateurs have not the same appliances nor the large collections that nurserymen have, and hence when such tropical weather as this comes and a plant or two is driven out of bloom they are nonplussed; yet in some of the classes, notably in the zonal Pelargoniums, their plants were better than the nurserymen's, being more compact in growth and more full of bloom; and in Ferns and Lycopods and Fuchsias there were some remarkably fine exhibits.

Amongst cut flowers the most telling stand was that of Gla-

diolus sent in by Messrs. Kelway & Son, the well-known raisers of Langport. With one exception, that of Shakespeare, their flowers were all of their own raising, and were of their usual excellence. It is, however, useless to give the names, as probably many of them may not be in commerce for years to come; and purchasers would do better to let Mr. Kelway choose those he may send rather than trouble themselves with names, of which they will have probably to be told "They are not on our list yet." And no description can give any adequate idea of the colouring of the flowers. Two of them, Mr. Marshall and Dr. Woodruffe, were awarded first-class certificates, the former named after the enthusiastic owner of Belmont close to Taunton, and the latter the indefatigable Secretary of the Society.

I was sorry to see so few competitors for the ladies' prizes, but those which were exhibited were very good. Miss Cypher of Cheltenham arranged a table with her usual excellent taste, and the dinner-table stands were all in good style. In the cottagers' productions the fruit and vegetables fell somewhat short owing to the dry weather; but one was astonished to see such Carrots, Onions, and Celery exhibited in such a season.

A brilliant day (so different from the gale of two years ago) added of course greatly to the success of the Exhibition. The Secretaries and Committee worked hard to make all go straight, and I should imagine that in a pecuniary sense their efforts must have been successful, and that the Taunton Deane Horticultural Society has in this summer of brilliant sunshine scored a success.—D., *Deal.*

## ROYAL HORTICULTURAL SOCIETY.

AUGUST 16TH.

**FRUIT COMMITTEE.**—H. Webb, Esq., in the chair. Several Melons were submitted to the notice of the Committee, but although many of them were imposing in appearance they were deficient in flavour. Mr. James Hussey, gardener to D. Pearce, Esq., Northend Villa, Hammersmith, was awarded a cultural commendation for four brace of Telegraph Cucumber. Mr. E. Luckhurst, gardener to A. Nesbitt, Esq., Oldlands Hall, Uckfield, sent two bunches of Ferdinand de Lesseps Grape, which were deliciously flavoured and perfumed; also Victoria Red Currants, which were very fine and similar to the unnamed dish that was exhibited from Chiswick at the last meeting; also very fine and well flavoured Early Rivers Peaches, to which a letter of thanks was awarded. An excellent dish of Victoria Nectarines was exhibited by Mr. Tillery, Welbeck, and received a cultural commendation. Mr. Flint, gardener to E. Lee, Esq., Loam Pit Hill House, Lewisham, had a similar award for good dishes of Royal George Peaches and Elruge Nectarines. Mr. Flint also exhibited good examples of the Golden Perfection Melon.

Mr. Turner, Slough, exhibited The Schoolmaster Potato, a round, rough-skinned, handsome tuber, which has been proved by the Committee to be of superior quality. The haulm resembles that of Bresee's Prolific, but is more compact in growth. A similar award was made to Messrs. James Veitch & Sons for a seedling, a handsome tuber, the plant being of erect growth. Mr. Parsons, Danesbury House, Welwyn, exhibited Magnum Bonum Onions, a selection from the Globe, and well grown. A collection of Apples, including Duchess of Oldenburgh, Charlemagne, American Crab, &c., was sent from the Society's garden at Chiswick. They were ripe and briskly flavoured, the American Crab being also attractive in appearance.

**FLORAL COMMITTEE.**—Mr. W. Bull in the chair. Messrs. Veitch & Sons exhibited a plant of *Dendrobium bigibbum* superbum, a rare and distinct Australian species, with purplish lilac sepals and petals, and a deeper lip; a valuable *Dendrobe* which is seldom seen, and which should be included in all collections. A first-class certificate was awarded. Mr. D. Ross, The Gardens, St. Martin's Abbey, Perth, was awarded a first-class certificate for *Lobelia St. Martin's Blue*, a compact-growing variety, having flowers of the deepest indigo blue and bronzy-brown foliage. It is highly distinct, and cannot fail to be valuable for bedding purposes.

Messrs. Kelway & Son, Langport, exhibited twenty-four varieties of *Gladioli*, for which a vote of thanks was awarded. Of these, first-class certificates were given to Dr. Hogg, a charming variety, the centre of the petals being white edged with very bright rose, and blotched with cerise; to Lady Aberdare, a large and crimped flower, bluish, blotched and barred with deep rosy purple; and Rev. J. M. Berkeley, a very full and smooth flower, cerise with scarlet flakes, a fine variety. Similar awards were made to Mr. Barron, Elvaston Nurseries, Derby, for *Cypripedium Lawsonsia elegantissima*, and *Retinospora tetragonia aurea*. The former is the most intensely golden of all Conifers, the stems as well as the foliage being yellow; and the latter is extremely attractive, is of pyramidal habit, green, heavily tinted with yellow, and of compact feathery habit.

Mr. Turner, Slough, exhibited eight varieties of Dahlias, two of which—Drake Lewis and Canary—received first-class certificates. The former a seedling from John Standish, and is exceedingly deep and full; it is of an intense scarlet colour, and

undoubtedly possesses great merit. The latter is a well-formed flower of pure canary yellow, and very attractive. Mr. Turner also exhibited *Rose Royal Standard*, which was certificated last year, proving that it is not only a good Rose, but is a continuous bloomer.

First-class certificates were awarded to Messrs. Froebel & Co., Neumunster, Zurich, for *Begonias Miranda* and *Otto Forster*. These are of the *B. imperialis* type, having plush-like foliage with light markings, and are distinct and ornamental.

Mr. Roberts, gardener to W. Terry, Esq., Peterborough House, Fulham, exhibited two plants in 8-inch pots of the striking *Gloriosa superba*. The plants were laden with flowers, and a vote of thanks was worthily awarded for them. Mr. Chapman, gardener to B. Reeves, Esq., North End Lodge, Walham Green, exhibited *Crinum giganteum*, and received a vote of thanks. A similar mark of approval was voted to Mr. Spinks, gardener to H. Quilter, Esq., Lower Grounds, Aston Park, Birmingham, for *Lobelia White Beauty* and *The Gem*, the latter being after the style of the pink variety *Omen*. Both these are evidently useful bedding kinds. Mr. Laing, Forest Hill Nursery, exhibited a self-coloured *Fuchsia*, Lord Beaconsfield, a very free-growing and profuse-flowering variety.

As may be seen in our advertising columns, some able gardeners of the Society are disengaged, whom the Council are desirous of recommending to those needing their services.

## OUR BORDER FLOWERS—BELLFLOWERS.

BELLFLOWERS are found in almost all parts of the habitable globe (many of them continuing in bloom for months), and are grown in most gardens, from the palace to the cottage.

Such kinds as *Campanula pumila*, *C. pulla*, *C. pusilla*, *C. Barrelieri*, *C. garganica*, are charming plants for summer for edging purposes. In some of our northern counties the last-named species may often be seen in many windows—one of the most beautiful of window plants, continuing in bloom for months. I have known *Campanula carpatia* used as a bedding plant, and for a light blue bed it is very effective. *C. muralis* is a lovely border plant, and ought to be in every garden and on every rockery, as should those named above. *C. hederacea* is a most attractive plant, requiring care, and in some situations protection; it is a charming plant in a cool fernery under glass. Perhaps the most striking kinds of the family are the blue and white *Campanula coronata*. They are telling plants for exhibition purposes, as are many other kinds. Many of them are useful for pot culture and indoor decoration. For this purpose none are better adapted than *Campanula Van Houttei*; it is one of the finest of the race. They are all easy to cultivate, and are easily increased by division. Some may be raised from seed. They require good sandy loam and drainage, water when required, and room to develop themselves. The taller kinds require staking to protect them from being broken by the wind. They will well repay any extra care bestowed upon them.—VERITAS.

## NOTES AND GLEANINGS.

At a convened meeting of the WIMBLEDON GARDENERS' SOCIETY held in the Institute on Tuesday evening, August 8th, to arrange for the recommencement of their evenings' reading and debating class, after a recess of two months, Mr. Ollerhead proposed that they should re-open their meetings with a social supper to which a number of eminent horticulturists should be invited, the supper to take place in the Lecture Hall, and to be arranged for on easy terms, so as not to shut out anyone residing in the outlying or other districts who may wish to be present or take part in the proceedings. Supper being over, a lecture or subject relating to horticulture to be brought forward for discussion. This motion met the unanimous approval of the members present, and a list of about fifty who were desirous to join was at once jotted down, which number is expected to be greatly increased. Those residing at a distance desirous to take part in the proceedings may communicate with Mr. James Ollerhead, The Gardens, Wimbledon House, S.W., on or before the 22nd day of August, as the supper is arranged for on the 25th. A vote of thanks to the Chairman (Mr. Ollerhead) closed a very agreeable and pleasant evening. Mr. Ollerhead was the originator of this Society.

— A MEETING of the members of the PELARGONIUM SOCIETY will be held on Wednesday, August 23rd, at noon, in the Chiswick gardens, to inspect the collections of Pelargoniums growing there, and to discuss matters relevant to the objects of the

Society and its arrangements for the ensuing year. A luncheon at 5s. each will be provided at 2.30 P.M. for those who inform Mr. Barron (Royal Horticultural Society's garden, Chiswick, London), not later than the 21st inst. of their wish to partake thereof.

— At the Alexandra Palace, in Mr. J. T. Peacock's collection, there are at present three very rare AGAVES in bloom—*Agave laxa*, *A. Besserriana*, and *A. bromeliæfolia*.

— MESSRS. EWING & Co., nurserymen, Norwich, have sent us fruits of two sorts of PLUMS both ripe with them some time before Rivers's Early Prolific (both are ten days later this season than usual). Blue Perdrigon they have been gathering this season since the 7th of July, and it is of fine quality as usual, and a great bearer. Hubbard's Early Prolific is just (August 11th) coming fit; this is a great bearer, but the quality is poor; in size it is superior to Rivers's Early Prolific. The only two places round Norwich having a fair crop of Plums this year are their own orchard, and the other at Somerleyton Hall near Lowestoft. In the latter place the large Apple trees are nearly destroyed by American blight. In west Norfolk the market gardeners talk of Plums being worth 1d. each.

— QUITE a feature just now in the border outside the curvilinear range at Glasnevin is *CRINUM ORNATUM*. Fancy a *Crinum* with a stem nearly as thick as that of the giant *C. amabile* of our stoves, with flaccid spreading leaves, each some 5 feet or more in length, and where widest half a foot broad, with a flower stem 4 feet high, and thick and stout as a walking-stick, and crowned with an umbel of a score of pendulous, white, rose-tinted flowers, each nearly as large as that of the *Belladonna Lily*, and the reader will have a good idea of this grand *hardy Amaryllid*. Yes, perfectly hardy; for some six years or so have it and its companion plant, *C. Moorei*, stood out without the slightest protection, and among these years were some of a character to make the test of hardihood one of the most crucial kind. These two magnificent *Crinums* are gains indeed to our gardens, and for their introduction and the interesting fact of showing their hardihood the lovers of choice hardy plants have reason to feel indebted to Dr. Moore and Glasnevin. There are several other new and interesting plants in flower there just now, among others the stately *Natal Hyacinth*, *Hyacinthus candicans*.—(*Farmers' Gazette*.)

— MR. THOMAS SHORTT writes that *GLORIOSA SUPERBA* is quite hardy, and succeeds if planted in light rich sandy soil in a dry situation—at the foot of a wall or on rockwork, perfect drainage being indispensable. A few ashes or fern placed over it will be of service in severe winters.

— THE application of the term *MOTHER*, whether to plants or other natural objects, intimates that it was considered the origin, the parent of some speciality. "Mother of Thyme" intimates that it is the producer of incense, it is fragrant all the year; both in Greek and Anglo-Saxon Thyme refers to incense or perfume. "Mother of Pearl" is a lining of the shell of the oysters which yield pearls. "Mother of Millions" is the popular name of the *Linaria Cymbalaria*, and was supposed by the old herbalists to promote fecundity.

— We earnestly commend the following extracts to our readers, and emphatically say "Do likewise."—"It has been one of my greatest pleasures during the past year to distribute some hundreds of bunches of flowers to the sick and infirm poor, and in every case the gift has been received with grateful thanks. Through the kindness of those who have sent the flowers, often the choicest their gardens afforded, many a lonely widow's heart has been made to rejoice, and many a sick one has been cheered and helped on towards recovery: and the rich perfume they shed in the sick chamber has at once been a solace and a joy. One poor old lady who had been ill a long weary time, when I took her a bunch of flowers said, 'It was like bringing the Garden of Eden into the room.' Another, who had not spoken for a long time, found her long-lost speech in praise of a beautiful little bouquet I had placed on a table at her bedside. Cases might be multiplied, the only difficulty being to find one where the flowers have not been like angels' visits." "The following is from the matron of our General Infirmary:—'Flowers in the wards of a hospital not only help to enliven the dull monotony of the wards, but, by affording some new train of pleasant thought, they enable the patients, for a short time at least, to forget their sufferings. Often have I seen the pained face of a patient light up with a smile at the sight of a few spring flowers. Rely on it, it is such small delicate attentions as these, showing that some-

body takes an interest in them, and looks on them, not as logs of wood, but as men and women having sympathies and affections, that make all the difference to the comfort and contentment of the sick. The following instance shows how the flowers are valued:—A fisherlad of sixteen had his leg so severely injured that amputation was necessary. A day or two after the operation somebody sent a present of a few Violets, and the notice and care he took of them would have well rewarded the donor. One day an attendant pretended to take them away, on which he said, 'No! you may take away my dinner or my wine, but you must not take away my flowers.'"

—(*Report on Distribution of Flowers at Hull in 1875.*)

— THE "American Gardeners' Monthly" states that "the EXHIBITIONS OF FRUITS at the Centennial promise to be a great success. Horticultural societies from Iowa, Michigan, Kansas, Indiana, Massachusetts, Ohio, and Canada have asked for space for ten thousand plates for the 12th of September exhibit. It will no doubt be the most wonderful sight ever seen in the world, and Philadelphia ought to be the great central point for horticulturists in September, 1876." It is further stated that a choice collection of plants exhibited by Messrs. James Veitch & Sons of Chelsea have been presented to the city of Philadelphia.

## THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 11.

RAPID have been the changes that have passed over London nursery gardens during the last fifty years; so much so, that a map of London prepared to indicate these in the "good old times" when the Prince Regent had become King, and one showing the present extent and localities of these useful establishments, would exhibit a wonderful contrast. Only here and there does a nursery survive which approximates to the busy parts of London, and the owner of which has refused to listen to "the voice of the charmer," preferring to go on in the old style that his father, or perhaps his grandfather, did before him, though the smoke of the metropolis is sadly opposed to his successful cultivation of any plants that require a pure atmosphere. And in these days, when it is so easy to convey plants, flowers, and fruit from one place to another, there is little need that a man should locate himself near the metropolitan districts, and those are the wiser cultivators who have chosen spots some ten or twelve miles out on the pleasant slopes of north Middlesex, Kent, or Surrey. Yet somehow one laments over the nurseries that have vanished and fled with all their greenery to make place for long lines of doors and windows and the bustle of London streets; but even more disagreeable to a person of any taste at all is the aspect of a neglected nursery garden, where the paths are overgrown with grass or trampled out of outline, the buildings are in a miserable state of dilapidation and besprinkled about with smashed glass, while on the beds innumerable weeds disport themselves. Such was the condition of the once-celebrated Sloane Street Nursery, the career of which has now closed, when I visited it a few days ago. It is satisfactory, however, to find that the land is neither to be built upon nor to remain in its wilderness state, but that by-and-by it will be laid out afresh, and under the name of "Cadogan Gardens" serve as a resort for the well-to-do residents of the streets overlooking it. The juveniles will be cared for, doubtless, and croquet lawns with flower beds will serve to delight visitors of all ages, and with judicious management the existing shrubberies can be utilised. But it will not need the lapse of many years to make people forget its history as a nursery garden, which goes back to the time when Chelsea was separated from Pimlico by that ominous waste designated the "Five Fields," and the glories of Ranelagh were fresh in the memories of the folks living in the neighbourhood.

A hundred years ago or more there were two contiguous estates in Chelsea, one much larger than the other, known as "Whitelands" and "Blacklands." The latter of these, indeed, extended into Pimlico and Knightsbridge, consisting of something like a hundred acres. Old chroniclers have not troubled themselves to explain the origin of the name, and my conclusion on the subject is this, that "Blacklands" was not thus called from the actual tint of the soil, but because the surface appeared dark through its being covered with the purple bells of the Heath (*Erica tetralix*). The sandy soil would suit the plant, and there is extant evidence that it once grew plentifully on the common which adjoined the Blacklands

estate. As in the eighteenth century—at least during its early part—people very absurdly called a man “black” who was only of dark complexion, it is quite conceivable that Londoners called a plot of land black which was purple and dark green by reason of the plants covering it. Of this land, in 1771, Mr. Holland took a lease and commenced building upon it, though the work proceeded slowly, and large portions of the ground were still in hand at the beginning of this century; and hence the owner was but too happy to allow some six acres abutting on the then newly-formed Sloane Street to be laid out as a nursery garden. In fact, however, the aims of its originator, as we shall see, went beyond that, and he projected a kind of botanical garden, which was to afford instruction as well as recreation to the west end of London, so that he deserves honourable mention as a pioneer in a direction where much yet remains to be done, for the study of botany needs further popularisation, and especially is it still insufficiently taught in our middle-class schools. Brewer, in his account of Middlesex, credits the illustrious botanist William Curtis (well known through his “Botanical Magazine” and other valuable works) with the establishment of the Sloane Street Nursery; but as he was peaceably interred in Battersea church in the year 1799 there must have been a mistake about this, since the nursery dates from 1807. Possibly the scheme may have been spoken of in his lifetime, though circumstances postponed it. He and his partner, Mr. Salisbury, had a nursery ground at Brompton or “Little Chelsea,” concerning which there is a lack of information, and after Curtis’s decease Mr. Salisbury decided to remove to Sloane Street. This was the same Mr. Salisbury who had at one time a fine piece of property at Chapel Allerton in Yorkshire, and who subsequently became possessor of a large garden at Millhill which had been formed by Mr. Collinson. The Sloane Street Nursery having an extent of about six acres—more than double the ground belonging to the older Apothecaries’ garden on the bank of the Thames—was regarded as of little less importance by the botanists of that day, and indeed it was dignified with the title of “Botanical Garden.” Nor was the epithet unmerited, for on the original plan carried out by Mr. Salisbury the greater number of the hardy and half-hardy plants were arranged in divisions according to the Linnean system, and therefore we may presume also labelled for the benefit of those persons inspecting them. Botanical lectures were given in the months of May and June, and a library was commenced containing not merely books on botany, but on entomology in addition, and some upon general natural history; and it does not surprise us to read that entomological works were placed here when we find that amongst the frequent visitors to the gardens was A. H. Haworth, the painstaking collector of British and foreign insects, and who is said to have captured the first specimen known of that bee parasite *Stylops Melittæ* at Little Chelsea in 1797. Besides his entomological attainments he was no mean botanist, and his “Observations on the Genus *Mesembryanthemum*,” his “Synopsis of Succulent Plants,” his “Revision of the *Narcissuses*,” and his “Enumeration of the *Saxifragæ*,” though now to an extent obsolete, bear testimony to his attainments.

Faulkner in his history of Chelsea dwells with much satisfaction upon the delightful promenade these gardens afforded, though at that time the trees must have been comparatively young. One is inclined to doubt his assertion that the walks were so contrived that an individual could walk nearly two miles without having to re-enter a path along which he had already been. The greenhouses and forcing houses were at first few in number, and the practice of forcing plants by hot-beds with dung placed behind walls of boards was followed, though Salisbury’s successor advanced beyond this very primitive mode. This successor was a Mr. Tate, who was, however, somewhat annoyed by the interference of the inhabitants, who seem not to have admired the scientific element that had been brought in. Greater facilities were given for the use of the ground as a promenade, the name “Botanical Gardens” was dropped, and the interior of the place laid out differently, the Linnean arrangement being superseded. It was in 1820 that Mr. Tate became the occupant of what was now called the Sloane Street Nursery, and from a recent examination I conjecture the disposition of the ground has not been altered much for fifty years or so. The outer walks or shrubberies, enclosing open spaces in which flowers, fruit, and vegetables were cultivated (not many of the latter, apparently, of late years) are still suggestive of Salisbury and Tate. There is an overpowering number of Lilacs, Laburnums, and Elms, while the Elder

and Hawthorn figure here and there, and there are scarcely any of those exotic shrubs and trees now so common in gardens and shrubberies. In one part I was rather amused to discover a row of English Hazels, to the nut-producing power of which London smoke has not been favourable, nor as a rule is this a tree grown for the purpose of affording shade in our nurseries. Of shade there must surely have been almost too much in this nursery; and though there would be plenty of that valued article leaf mould (for lack of which it is said the trees in our west-end parks suffer severely), one can fancy the grumbles indulged in by those who had to sweep the walks and clear the beds in autumn. And when there was a rich London fog of the kind the metropolis was more familiar with a score of years ago than at present, thanks to improvements in drainage, the shrubs must have kept it in after it had settled down in the open plots towards the centre of the nursery, a result also aided by the fact that the whole ground sinks below the level of the surrounding thoroughfares.

As a proof how largely Mr. Tate helped to advance horticulture by his cultivation of exotics, especially under glass, Mr. Faulkner quotes the names of some of the recent additions to the nursery, when he wrote in 1829. Mr. Ballock had supplied Mr. Tate with many Mexican plants collected by himself; and Mr. Ackerman, who had travelled in South America, others from that continent. Capt. Paterson contributed to the collection a variety of Chinese species, including several new and choice Azaleas. From Mr. Brown Ceylon plants had been sent in, notable amongst which was *Barringtonia speciosa*. Mr. Staples had procured many rare plants, especially Cacti, and Lady Amherst species from various countries. The collection of Orange trees was pretty large, Faulkner says, surpassing then any other collection in the neighbourhood of London. It was with a peculiar interest that I surveyed some dismally ragged Azaleas now growing here that were struggling against the combined hostility of the dry weather and a swarm of Thistles, for I imagined them to be the descendants of those referred to by Faulkner.

This nursery, now just closed, had been for many years in the hands of a family of the name of Tuck. Soon after, Eaton with other Belgravian squares began to cover the land called the Five Fields. Mr. Tuck occupied one of the enclosed six plots in Eaton Square as a nursery garden, at that time the Square being far from completion. This was the central plot on the right looking towards Chelsea; but as ere long, with increasing houses, the residents required that the whole space should be given up to their use, the nurseryman had to withdraw—somewhere about the year 1842 I think; and probably Mr. Tuck’s connection with the Sloane Street Nursery dates from that time, though I cannot ascertain the precise period of Mr. Tate’s decease or his relinquishment of possession. Some of the buildings would date back thirty years, perhaps erected by Mr. Tuck on his entry; others are evidently much older.

It seems a pity that, as at this moment, weeds should be suffered to run riot over the ground, and since official persons must move slowly in improvements, delaying the re-arrangement of the place, it would have been as well to have given away the remaining plants, instead of leaving a large percentage to die of neglect. In such cases it is always curious to note what weeds grow most profusely, and besides Docks and Thistles, I was struck with the abundance of the Dog’s Mercury (*Mercurialis perennis*), and rather astonished to see sundry specimens of one of the native St. John’s Worts (*Hypericum* sp.), with such flourishing young plants of *Conium maculatum* that I thought of attempting to drive a bargain with some of the chemists in the neighbourhood. I should have stated before that there is a tradition to the effect that the American blight was first observed in England upon an Apple tree in this nursery.—C.

#### LARGE ROSE FOLIAGE.

THE Rose tree from which the leaf was taken was purchased by me from Mr. R. Smith of Worcester, and is a *Maréchal Niel* grafted, I believe, on the *Manetti*. It was in a pot when I received it, and was planted out in the border of my greenhouse about the latter end of March. About the spot where it was planted existed an old cesspool. I presume that the roots in their search after food have found this out. If this be so it only shows what rich food the Rose will digest. Since it has been planted out in the border it has not blossomed, but it has made an average growth of from 12 to 15 inches

Fig. 17.—LEAF OF MARÉCHAL NIEL ROSE, NATURAL SIZE.

a-week. This fact was pointed out to me by some workmen who were fixing some hot-water pipes, and they took the trouble to actually measure the growth from week to week. It has many of its leaves, I think, quite 12 inches long, and the sight of them hanging from the roof is very grand. If anything, it seems to increase in vigour and strength. I have two other plants of Maréchal Niel planted out in the same border in rich soil, but they are pigmies in comparison.—H. W. SOREL-CAMERON, *Belvidere, Weston-under-Penyard, Ross, Hereford.*

[The accompanying woodcut is an exact copy, and of the exact size of the Rose leaf.]

## EARLY WRITERS ON ENGLISH GARDENING.

No. 17.

WILLIAM FORSYTH.

HE was born some time in 1737 at Old Meldrum in Aberdeenshire, and was there early initiated in the horticultural arts, but completed his pupilage by being placed during 1763 under Philip Miller at the Chelsea garden of the Apothecaries' Company. At Miller's recommendation he obtained the head gardenership to the Duke of Northumberland at Sion House—a situation which he resigned in 1769 to succeed his old master in the curatorship of the Chelsea garden. He retained this appointment until 1784, and then resigned it upon succeeding Mr. T. Robinson in the office of the Royal Gardener at Kensington and St. James's. He held this appointment until his death, publishing during the tenure of his office, "Observations on the Diseases, Defects, and Injuries in all kinds of Fruit and Forest Trees, with an Account of a Particular Method of Cure Invented and Practised by the Author," 1791; and "A Treatise on the Culture and Management of Fruit Trees," 1802. In 1804 he died; and but for one circumstance, the testimony of his friends that he was "benevolent, unaffected, modest, and worthy," might have been inscribed without comment beneath his portrait. We are told that from the year 1768 down to 1789 he devoted much time to the cultivation of fruit and forest trees, but especially towards the discovery of some composition to remedy their incidental diseases and injuries. He laid claim to success in his research after this sanitative composition, for we have seen that he published "an account of a method of cure *invented and practised*" by himself, and Government gave him £1500 for the discovery. They proposed to double the sum upon certain facts being established by him; but in the meantime Mr. Knight, then President of the Horticultural Society, stepped forth in the discharge of a distasteful public duty—to dispute Mr. Forsyth's title to any reward. We have had occasion to examine minutely into the merits of the contest, and regret to have arrived at the conclusion that the composition Mr. Forsyth employed was borrowed from Hitt and other writers upon the cultivation of trees, and that the cures he alleged to have effected were not of the extent or importance certified. Mr. Forsyth's plaister for healing the wounds and restoring to vigour decayed trees was as follows:—One bushel of fresh cow dung; half a bushel of lime rubbish, that from ceilings of rooms is preferable, or powdered chalk; half a bushel of wood ashes, one-sixteenth of a bushel of sand; the three last to be sifted fine. The whole to be mixed and beaten together until they form a fine plaister. Now, there is nothing in this compound sufficiently differing from others recommended by his contemporaries and predecessors to entitle him to call it his invention; but supposing that an arbitrary difference in the proportions of the constituents suffices to sustain such claim, still what can be said in defence of his assertion that that composition has filled with young wood the hollow trunks of timber trees, and that he had in his possession parts of the trunk of a tree in which the new wood by the efficacious power of his "poor tree's plaister" had been made to incorporate with the old, and that trees so cured were rendered as fit for the navy as though they had never been injured? Every gardener, every physiologist, knows that this could not be true. New wood and new bark may be induced to grow over old wood, but no power, no application, will induce them to unite to it. It is quite true that Dr. Lettsom, Dr. Anderson, and others, who ought to have been more circumspect, certified that Mr. Forsyth's statements contained "nothing more than the truth;" but they afterwards either acknowledged that they did so on evidence that ought not to have been deemed sufficient, or that they meant no more than to testify in favour of "the utility" of Mr. Forsyth's plaister. Of this there can be no doubt, because every application excluding the rain and

air from a tree's wound is of great "utility." It is also quite true that Mr. Forsyth received a parliamentary grant of money, but it was granted upon inconclusive evidence, and, as Mr. Knight observes, affords a much better proof that he was paid for an important discovery than that he made one. The whole of the correspondence on the subject between Mr. Knight and Dr. Lettsom can be referred to in the seventy-fourth and seventy-fifth volumes of "The Gentleman's Magazine," and may be read as a warning how literary controversy should not be conducted. Dr. Lettsom had rashly attested to the truth of that of which he was not a competent judge, and had not the noble candour to seek a fair examination; whilst Mr. Knight poured forth insinuations and charges in a wrathful tone, very unbefitting either a philosopher or a gentleman.

Fig. 18.—W. Forsyth.

There is much relative to this plaister in the "Forsyth Correspondence" published by us in the *Cottage Gardener* in 1851. In the November of 1799 Mr. Forsyth's wife died, and in the "Correspondence" there are testimonies of her excellence. I do not know the number of their children, but two sons are mentioned in the letters.

Besides the works named above Mr. Forsyth published "A Botanical Nomenclator" in 1794, and on "Gathering and Preserving Apples and Pears." He also contributed to the Transactions of the Board of Agriculture on various modes of promoting gardening among all classes.

Mr. Wedgewood, writing to Mr. Forsyth in 1801, first proposed the establishment of a society which ultimately became our Royal Horticultural Society. The genus *Forsythia* was named in his honour by M. Vahl.

## THE ARRANGEMENT OF PLANTS AND CUT FLOWERS FOR INDOOR DECORATION.

IN disposing of an assortment of plants in bloom to produce a general harmony of colouring in a mixed group, or even in making a nosegay, the same colours should recur at least twice if not thrice. One of the masses of colour ought to be larger than any of the others of the same kind, and the other one or two masses or specks ought to be of different sizes, and not so far distant from the first or principal mass as not to be easily recognised by the eye. This necessity of two or more portions of colour of a principal mass, and of secondary

specks, is derived from the principle that there must not only be parts but predominating parts, all tending to one harmonious effect. Therefore, in arranging flowering plants in a conservatory, or for the furnishing of rooms, each colour should be carried on in the same manner throughout.

One great object in grouping plants and flowers in conservatories, rooms, vases, baskets, and epergnes for dinner-table decorations, is not to have a bewildering excess of gay flowers. It requires good taste to manage many colours without producing weakness and confusion. The great need is to have a background and a carpet of green. The *Lycopodium denticulatum* is the best carpet plant that I know of for the purpose. Any green leaves will do for the background. Then, if your plants are all in flower, this is the place to show them off to the best advantage. Do not crowd them, but scatter them about in clusters with some of the choicest gleaming up in unexpected places. Such groups are very effective.

In dinner-table arrangement the safe rule is to keep to simple contrasts. I have seen tables look hideous with clumsy piles of flowers dressed-up, trimmed, and stiffened, and made so artificial that all traces of nature were lost, their leaves stripped off, and the colours pressed-up together with scarcely a twig or green spray to be seen. The tide does, indeed, seem turned against the crowded flower-stands, and the heaped-on colours that used to fill-up epergnes and encumber drawing-rooms and dinner tables.

Nothing has done more to bring about this change than the good taste of the judges at flower shows. People have such different tastes in arranging flowers that it really becomes a difficult point to write upon; still everyone can say what they have seen look well. I for one have great faith in decorations that look natural and graceful, and that can only be achieved by a free use of foliage plants. Ferns being the most suitable, their fronds being so beautiful, and they enhance also the beauty of flowers.

It is a safe rule to vary the shades and quantity of green according to the flowers—namely, if the colours of your flowers are bright, and red predominates, the foliage must be dark green and plenty of it. If the flowers of these shades are delicate the green may be delicate also and less of it. This lesson with many more we can take from nature. In the spring all nature is decked with pale green bespangled with soft delicate colours, and as the season advances the greens darken and the flowers brighten. Surely from this we might learn how to arrange them best as a work of art. Who can look at the colours of nature so bright, so bold, so sensitively soft, so freely distributed, yet so charmingly adjusted, and not learn a lesson therefrom? The groundwork always judicious in tint heightens the lustre of all above it. Look at the tints upon the rock—every shade of grey and gold, green and red; the beautiful Heather and shining golden Gorse, with blue and grey marl and stones—a mingling of such colours that cannot but be admired. Who could find fault with our moors and mountain sides covered with the rosy flush of the pink Heath Bells, and near them the ground carpeted with Blue Bells, the purple Violets, and the Primrose tuft nestled beneath the bowery hedge on which hangs the wild Rose interwoven with the waxy Honeysuckle with its coral points and ripening berries clustering, and waving, and twining themselves into garlands? In nature we see flowers that hang on and festoon the steep sides of rocks, and the dark brown trunks of trees, and that cling to old grey walls. Then from nature let us take our directions for the arrangements of flowers for the drawing-room and dinner table.

We must say something about the vase containing them. Brown baskets, white marble, and glass, these are the most suitable in which to group flowers. The glass vases, baskets, and stands that Mr. March designed are particularly appropriate, and are generally admired.

In a group of three the centrepiece should be the keynote, and ought to be a few inches higher than the others. They should be filled with flowers distinct from those in the two ends, which may be made to match. The general arrangement has to be considered, and must be ruled by a colour agreeing with the centrepiece, that the colours may make a harmonising whole. On the contrary, if the three vases were to contain the same coloured flowers we should have a most heavy-looking and yet disjointed picture.

The loveliest vases that I have seen exhibited were those shown by Miss Hassard of Upper Norwood. Her arrangements are exquisite, they have always a light and elegant appearance. The feathered Ferns are placed to form a drooping ring of fresh

green fronds around the edge of the vase. This seems to be the first consideration. Then all around again a fringe of drooping flowery sprigs of brilliant colours spreading and nestling in the cool green Fern leaves. Then the centre is filled with harmonising colours, the full beauty of every flower being visible, and to give a still more natural effect a few tasseled spikes of Grass are seen dotting and waving above the whole. All is done with a truly artistic touch, grouped and shaded without a discordant tint.

If we have flowers which do not accord together they force us to crowd them, and half the beauty of flowers consists in the graceful shape of each special spray, and it does seem perfect waste wedging and massing as much together as, if rightly used, would be sufficient to fill half a dozen vases.

After mentioning the principles which guide us in the arranging of flowers it is not necessary to dwell in detail of the varieties to be used, for these are decided by local circumstances, and are dependant for their effect on individual taste and dexterity.—N. COLE.

## ORNAMENTAL AND USEFUL TREE-PLANTING.

No. 1.

To say that every Englishman has an innate passion for tree-planting is a truism which needed no Washington Irving to inculcate it, though indirectly his testimony from across the Atlantic evinces the superiority of this passion to the accidents of country or climate. It is a fact that Americans grow rapturous at the sight of the stately Oaks and Elms of the mother country, as if discriminating between these adornments of our parks and gardens and the giant tenants of their own forests and prairies, with a partiality for the former. But that this penchant is exceptionally national becomes more patent if we attempt to assess the difference between the associations of the ancients as to forests, trees, and woodland scenery, and those which they call up in the British mind. While Greeks and Romans seem to have identified a plantation with a dense, dark, or sadly-sighing body of trees, they are seldom found exulting in the changeful hues of the greenwood, the soothing walk under the bee-haunted Limes, or those sylvan courts of leafy verdure which tempt the most unromantic to envy the forester and sigh for the freedom of Robin Hood and Maid Marian. Athens, it is true, could boast its Oaks of Parnes; but these were most considered for the sake of their charcoal, the Olive being the tree which quickened, beyond others, the pride and enthusiasm of its poets. There were Beech groves in the mountain districts of Greece, on the range next below the Pines; but the Beech does not seem to have had any strong attraction for the Greek eye, though its glossy green is such a charming feature in our parks and glades. The Plane, indeed, in their poetry meets with the commemoration due to its light green feathery foliage; but if we pass in review the items of Greek arboriculture, it will be seen that the Fig and Pomegranate claim scarcely less notice, and that perhaps their chief affection was bestowed upon the Cypress and Myrtle, the Tamarisk, and such lesser shrubs. From the Romans no doubt Great Britain derived not only a goodly addition to her indigenous trees, but also the first rudiments of the culture of this class of products. Besides our best fruit trees, they are held to have naturalised the Chestnut, Lime, Sycamore, Box, and Laurel. They may also have introduced the Beech, seeing that, according to Cæsar, it was not found in Britain, and that its Welsh name *Fawydd* (th. *Fagus*)—(Hereford derived its Welsh name of *Tre-fawydd* from the Beech trees near it)—smacks of a Latin origin. The English Elm, too, which is essentially a southern tree and rarely seeds in England, may easily have been introduced by them with the Vine; and to them in all probability we owe our first initiation in forestry, the art of rearing coppice-wood for Vine poles, Willows for wicker-work, and timber for house and ship-building.

Howbeit we have outstript our teachers; and, as much from inborn predilection as from a constant tradition of the pleasure and profit of tree-planting, so far covered with indigenous and imported tree growths the hills and dales, the waste places and green swards, the suburban spots and rural spaces of our island, that its levels are disguised by a variety of belts and coverts; its uplands clothed with Larch and Firwood; its parks and gardens embellished by ancient sylvan giants and audacious rivals from across the seas; its lesser holdings dotted with fancy Conifers and interesting triumphs of persistent acclimation; and, to come to London and our great cities, each square and crescent has its mimic park. There are

many reasons for this. Not only is it a matter of general experience that timber, whether in large or small quantities, is remunerative from its applicability to building and repairs, but our soils and climate, we find, may be sensibly improved by judicious planting. By this we may shut out the importunate blast, by this screen off the burning sunshine. The effect of such shelter is to double the value of inferior tracts; and this both because the influence of woodlands softens the temperature and conciliates the fertilising rain, and also because trees enrich the soil by deposits of vegetable matter, and by their roots open up the land to the action of air and water. Not often, perhaps, is the impulse to plant traceable to such solid and scientific causes: it is mostly due to the sense of delight and administration which an owner of land—be his paradise a few acres or half a shire, it is all the same—experiences in having a hand and a voice in the laying-out of his demesne; in visiting and revisiting his copses and nurseries; in watching his trees and shrubs wax in grace and stature, till they become to him a living interest, and he notes their habits as fondly as those of his children. So fruitful and attractive is the practical study of the subject, that it is a wonder we have suffered our neighbours across the Channel to be beforehand in the institution of colleges of arboriculture; unless, indeed, it be that, as we observed in the outset, in England every man is *in esse* or *in posse* his own planter, and it is a rare exception to find a proprietor who would devolve on a Nesfield or Capability Brown the experiments in landscape gardening which make up half the charm of the country gentleman's existence. Indeed, there are few fields in which the errors of inexperience may be retrieved more easily than in tree-planting; for though it may often occur that a single tree or a group proves a mistake in a given situation, it is exceptionally rare to find cause of regret in judicious thinning, or timely removal to another site.

So many excellent treatises on the planting of trees and shrubs have issued of late years from the English press, and Mr. Laslett's recent volume on "Timber and Timber Trees" deals so exhaustively with the commercial and economical aspect of the subject, that for details we might well leave the field to the weighty authorities named at the head of the present paper. It is beyond the scope of a review to linger upon cautions when and how to plant, or to supply the reasons why, in a stiff soil, the holes into which young trees are to be inserted should exceed the average 2 feet square and 18 inches in depth. Yet it may not be labour wholly lost to set down in what follows a few results of blended book-lore and observation, and to gather up from the romance and the realities, the accomplishments as well as the possibilities of arboriculture, persuasive to the deeper study and practice of it by every grade of landowners.

Amongst this fortunate class—fortunate, let us hope, in spite of the tendency of the unlanded classes to cast on the soil as many national burdens as the agricultural worm will bear without turning—those are most to be felicitated who find park and forest ready to their hand, and who have not so much to project fresh plantation of undulation and upland as to study the art of judiciously thinning, and to ascertain by what hardy native or well-recommended foreigner to replace some giant of the chase which the wind has prostrated. Yet even such have a deep interest in the experiments of acclimatization, and rare opportunities of adding novel grace to the native charm of their ancestral homes, there being this satisfaction in such introductions, that the old tree-tenants never regard new comers as interlopers; but Elm and Lime, Oak and Ash, Larch and Scotch Fir, evince the friendliest of spirits in harmonising with Cypress and Juniper, Deodar and Cryptomeria, the bright green Abies Douglasii, with its pale glaucous under side, and the pyramidal form and darker foliage of the spreading Wellingtonia or Sequoia. To the founder of an estate, the planner of the leafy shelters that are to protect, adorn, and ventilate his rising mansion, there is a more arduous field; one, however, in which (given thought and patience, with a grain or two of taste and an eye for landscape) he cannot easily go astray.

As a rule, his home, whether it is large or limited, will have a southern aspect; and in either case there will be more or less need to plant out the north. Where it is a question of park or parklike grounds, it is well to do this with a thick and dark massing of trees, so as to give an impression of depth to the northern boundary line, and to make the mansion stand out effectively from its background of dark-hued Conifers and of denser deciduous species. The actual depth of such a wooded background is of less consequence than the apparent;

but it adds vastly to the aspect of the demesne to have its northern boundary indefinite, and disguise or deception herein is perfectly admissible. The books recommend that such a plantation should be continued with wings of a bold sweep to east and west; and this may be correct in principle. But it may be doubted whether such a continuation would avoid the risk of over-formality, as well as of seeming severity, suggestive of a prison house or lunatic asylum, or one of those gloomy and isolated chateaux which would have exercised the fertile imagination of the horror-loving Mrs. Radcliffe. Shelter from the east, as, indeed, from the west, is desirable in due measure; but there may be excess of shelter no less than defect; and we believe that a practised eye will insist upon these particular barriers being broken and partial. A system of belts or groups, some more or some less distant, would have the desired effect; and if, perchance, on either side the frontier ground is a rising one, it is only to plant it with Larch or Scotch Fir to secure a perennial source of pleasure and profit. For the rest, the principle to follow is simple eye-service. If there is an unsightly feature to hide in the foreground it may be hidden by a well-plotted clump; if over another part of it the green sward stretches in a too unbroken range, or is diversified only by an ineffective hillock, it needs but to congregate there a few graceful trees, and you have the nucleus of a thing of beauty which will win upon the eye as it becomes developed by growth and years. In moderation, too, single trees should diversify the foreground: it is the best chance of rearing specimens that may hereafter be a glory of the district or county. An Oak, a Spanish Chestnut, a Wych Elm, thus expatiating in the liberty and range of the open ground, are worth turning aside to contemplate, and are so deemed by others than the poet or the sentimentalist. More than once have we seen a Larch, which, because it had enjoyed this freedom and never suffered the loss of its lateral branches through the proximity of other trees, has developed a grace and beauty second to none of the choicest Conifers in a habit of pendulous branches clothing its stem from head to foot.

One other special call for the planter is to the lake-side or stream-bank. To these he may add a new attraction, giving reduplication (so to speak) to the one by the trees which interrupt the uniformity of its expanse, and canopied by the other with subjects of weeping character and habit, arranged judiciously. Judiciously, we say: because the eye may tire of Weeping Ashes and Kilmarnock Willows; and while the mean between bareness and unbroken shelter is undoubtedly the thing to aim at, there is less risk of having to practise repentance after thinning the leafy guardians of a lake border than for any like exercise of the woodman's axe. Of course there are special trees for the waterside, as also for islands and other aquatic positions; but of the specialities of arboriculture, the likes and dislikes, aptitudes and inaptitudes of this or that hardwood or softwood timber tree we shall have to speak presently. What is more pertinent to this stage of our survey is the remark that what has been laid down as to parks and large grounds applies *mutatis mutandis* to smaller home-environs. The narrower the limits, the less field for multiplication of groups and clumps: but the shrubbery, the belt or border, which shuts out the oversight of unavoidable neighbours; the single specimens of curious tree or shrub, evergreen or deciduous; the study in these of harmony and contrast of form and colour; the avoidance also of undue encroachment on the green sward, and undue contiguity to the dwelling—these will be the pleasing solicitudes of the rural or suburban proprietor, whose area is more limited, but whose pursuit of arboriculture may be as intelligent and enthusiastic as that of the owner of a "dukery." With the former it is possible to refer to the records of the birth and growth of every tree in the garden. All are as children or congeners to their owner. Of the broad Oaks in the chases of Clumber or Belvoir, who is to say whether the planter may not have been—long, long ago—

"that bird, which instead of wings

Hath a spirit within him, that soars and springs—"

that most indefatigable of Oak planters, in his busy trade of transporting and burying acorns—the squirrel? Most of all, however, does the limited owner require to be on his guard against planting too near his house. A bright green or a gold-spangled dwarf is a pretty object beneath your west windows, or even those to the south-east, if there is tolerable shelter; but these dwarfs are apt to outgrow their early conditions, and without timely removal come to such dimensions that if they do not interfere with the chimney smoke, or clog the atmosphere which it is the office of trees to keep in a state fit for breath-

ing, at any rate they promote damp or mildew, and frustrate the growth of climbers and wall plants which might also have caught the sun that their bulk intercepts. Whilst a stretch of 60 acres will afford room for Oaks and Elms, Beech and Lime, Chestnuts, Sycamores, and Maples, as well as for Larch and other less everyday Conifers in suitable situations, and admit of the diversities of avenue, wilderness, grove, thicket, and clump, to say nothing of contrasts of colour in the foliage of the several seasons, it will be the wisdom of such as have but a tithe of that acreage to lay out to go in rather for a few choice Cedars, Pines, or Firs—hardy, ornamental, and useful, and to be content with the deciduous trees ready to hand, an Oak here and an Elm there, of such beauty and dimensions mayhap, that once felled no experience in choosing the most rapid-growing substitute could succeed in replacing it in a lifetime.—(*Quarterly Review*.)

## NOTES ON VILLA AND SUBURBAN GARDENING.

**THE PROPAGATION OF BEDDING PLANTS.**—No doubt it is quite right to advise amateurs to commence propagating as early as possible. My reason is that by beginning early almost all kinds of cuttings can be struck out of doors. One good and easy plan, as well as an economical one, is to level a piece of ground on a border exposed to the sun, and if possible to obtain some road grit or coarse sand and mix it well with the soil to about 4 inches in depth, breaking it up very fine with the rake, and then put a layer of road grit or sand mixed with leaf soil if it can be obtained, and if not good garden soil will answer very well, this to be placed on the surface about 3 inches thick, and to be made firm and level. In this the cuttings should be placed firmly and of a uniform distance apart. If the soil is dry the cuttings will be fastened by the quick return of the soil around them as they are put in, but if moist care must be taken that as the work goes on each cutting goes to the bottom of the hole and is properly fastened by the stick with which they are put in, then a plentiful watering will make all right. No doubt the sun will cause many of the leaves to drop off, but this must be considered as a natural consequence and in no way detrimental to the cuttings; and it is best not to attempt to pull off the decayed leaves until the cuttings are rooted, or the chances are that they will be disturbed and then die off. They must not be shaded, and if they are judiciously watered and a proper selection of cuttings made they will bear all the sun and will soon emit roots. The sorts that may be struck in this way are all sorts of Geraniums both plain-leaved and variegated, as well as Ivy-leaved sorts; then come Gazanias, Mesembryanthemums, and nearly any other sorts of bedding plants that possess vigour of constitution sufficient to withstand the exposure.

Alyssums, Verbenas, Heliotropes, and many other similar softwooded plants must be propagated in pots, or at least under cover, and shaded from the sun. Verbenas ought to be propagated while there is young growth to be obtained, for if hard wood is put in the cuttings are a long time in rooting, and even then seldom produce healthy plants. I have found it the best plan for those with limited convenience to root these cuttings in pots as early as possible, and have them potted off in store pots with good soil before winter sets in, preserving them healthy by frequent fumigations, and syringing to keep them clean, and keeping them pinched-in as they grow in order to make stubby plants.

Of course the striking of Geraniums outdoors involves the taking of them up, potting or boxing them, and placing them in close quarters for the winter, and to those who object to that I may say that the cuttings will root just as well if put in pots at first and exposed in such a place as I have stated; then they can be easily shifted if bad weather comes on, and the potting of them can then be deferred till the spring, which in some cases may be advisable.

For more tender plants, such as Alternantheras, Lobelias, &c., it is best to put up a frame on a slight elevation, when a little heat can be afforded in the absence of sun; here the cuttings soon root and do well.

I consider all sorts of plants that are to be kept through the winter ought to be rooted early enough to have them established before winter. Thus treated they are always healthier, more vigorous, and much less difficult to preserve than when they are struck late. Some may say that it spoils the effect of the beds to take cuttings so early, but if they are taken from the plants in a proper way very little disfigurement will be seen, and by beginning early they can be taken at two or three different times.—T. RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

THE warm showers gave us an excellent opportunity to plant out the waiting green crops, and more rain after planting has

given them a good start. In northern districts it is now time to sow Cauliflower seed for the earliest crop next year. It is best to sow the seeds on ground that is not rich, and the plants should be pricked out in fine soil as soon as the first true leaves are formed. When the plants are well established plant them about six in a hand-light, two of them being regarded as super-numeraries, to be subsequently planted out in the open ground in March. The plants which are not required for the hand-lights may be put out under a wall facing south or west, or they may be planted in a cold frame for the winter. These plants closely succeed those that were planted in the hand-lights. At Loxford we do not sow until the last week in August or first week in September. It is best to make two sowings, one two weeks later than the other; if the seeds are sown too early the plants are apt to button.

Prickly-seeded Spinach is sown about the same time for the winter supply. The ground ought to be deeply worked and well manured for this crop. It is as well to make two sowings of this, and the one should not be on such rich ground as the other. When the winter is very severe crops suffer the most on rich soil. Cabbage seed must be sown at this time; but some sorts have a tendency to run if the seeds are sown before the last week in this month. Last year we sowed Early York, Enfield Market, and Hill's Incomparable together, the result being that every plant of Hill's ran to flower, and not one of the others. If Hill's had been sown two weeks later in all probability this running would not have occurred. This is the most useful sowing of Cabbages and ought not to be neglected. The ground should be well worked and richly manured. The plants stand the winter best if they are pricked out into beds the same as has been recommended for Cauliflowers.

In light soils it is sometimes difficult to obtain a crop of Onions if the seed is sown in the spring. The maggot attacks them as soon as the hot weather sets in, and at that time the young plants are very easily injured. In a case of this kind it is very desirable to sow now, then the plants become established before the winter. We generally sow in rows about a foot apart. Early in February, if the weather is mild, the plants are thinned out to from 4 to 6 inches apart; the thinnings ought to be planted out the same distance apart as the others which were thinned. It is a very good time now to sow Turnip seed for the winter supply of bulbs. Small roots are most esteemed in the kitchen. We like a moderately rich piece of ground for this crop, and the seeds ought to be sown thinly; if the seeds are good it is not possible to sow too thinly. Some may say it is easy to thin out the plants when they are too thick in the rows; so it is if time permits, but young Turnip plants are easily injured when they are crowded together. We have had an excellent opportunity of harvesting some choice seeds; when the weather was fine they could be dried in the open air in a sunny position. With sufficient moisture there is another crop of weeds on the fresh-dug ground, but the Dutch hoe run through the soil amongst the rows of plants quickly disposes of them.

### PINES.

We have been re-arranging the Pines. The plants from which all the fruit has been cut have been thrown away and the suckers potted. The plants that have been arranged in the fruiting house are very stocky—many of them had thrown-up suckers. These were all removed, as no suckers are allowed to grow from the plants until they start into growth after their season of rest. Some varieties are very shy in producing suckers; other sorts, as the Queen, will sometimes throw-up half a dozen at one time. These ought to be removed in an early stage with the exception of two, which ought to be left on for stock. We do not usually remove them from the plant until they are of a large size, and this will be in June or July. If strong suckers can be obtained early in June they may be potted and grown-on to fruit next season, and fruit of the largest size and best quality can be obtained from such plants. The suckers potted now will not be repotted until the spring of next year. We keep the house rather close for a few weeks when the suckers have just been potted; but other houses have air freely admitted both at the front and back. All plants that are making growth have plenty of room. Overcrowding and insufficient ventilation are the causes of long narrow-shaped leaves, which produce inferior fruit. In all our houses a good supply of atmospheric moisture is kept up from evaporation. We never syringe overhead in very hot weather. The surface of the bed is syringed or watered, as well as the paths and walls of the house.

Fruit that is ripening in late houses requires to be freely exposed to light and air, and if the ventilators are fully opened there will not be much danger of the fruit being scorched. The Smooth-leaved Cayenne is very liable to be injured if the direct rays of the sun play upon the house when it is insufficiently ventilated; but this happens more often in the spring than at any other season. It is well to keep a good look-out for insect pests. Scale and mealy bug will sometimes appear in a mysterious manner, and it must be destroyed before it gains a hold upon the plants. The best way is to sponge it off with strong soapy water.

## ORCHARD HOUSE.

The house has not been forced so much as usual, but we gathered a good dish of Early York Peaches on the 2nd of August, and Rivers's Early York came in a week later. Early Grosse Mignonne, a very fine variety, is a little later, but it is far superior to either Early York or Rivers's variety. Following Early Grosse Mignonne closely is the Royal George, one of the most certain bearers and an excellent Peach. Grosse Mignonne and Bellegarde are rather later, and there are no better mid-season sorts. We have this season discarded Hunt's Tawny Nectarine, and shall now trust to Rivers's Lord Napier for the earliest. This sort, with the Pine Apple and Victoria Nectarines, will be grown for generations yet to come. If Mr. Rivers had not given us any other Nectarines, these three would have handed his name down to posterity.

The ventilators are now kept open night and day, and the trees are watered only when they require it. Too much water or too little is almost equally injurious to the fruits, and a little experience is necessary to arrive at the right medium. The same person ought to attend to the watering and care of the trees all through the season, as the surface-dressings applied to them are very apt to deceive; that part may be wet while the under part is dusty dry.

When the greater portion of the fruit has been gathered it is time to repot the trees. One half of the trees will be potted this year, the other half to be top-dressed later. Those trees that are repotted this year were top-dressed only last year. It does the trees no harm to disentangle the roots to a very considerable extent, the main object being to give the trees a supply of new food, and this may be accomplished by reducing the ball of roots. If  $1\frac{1}{2}$  inch of the fresh potting material can be rammed down the sides quite firmly it will be sufficient. This reduction of the ball is only necessary when the trees have been shifted into pots of the maximum size. In either case it is always best to disentangle the roots a little with a pointed stick or rod of iron. Good turfy loam rather of a clayey character is the best staple, and to it should be added a fourth part of decayed manure. We added chalk to our light loam, but did not notice any improvement therefrom.

## GREENHOUSE AND CONSERVATORY.

We make a good display with Phloxes at this season, and they form a very distinct feature. People tire of the monotony of scarlet Geraniums. In many places the largest proportion of the flower garden and flower borders are planted with them, and the houses are ablaze inside. They are certainly very useful plants, and are well adapted for decorative purposes. They are easily grown and propagated, and for this very reason everybody grows them. They are not more easily grown, however, than Phloxes. Our plants were propagated in the spring from cuttings put into a hotbed in March, and each plant has one strong spike. They are grown through the season in 5-inch pots. After flowering the plants are cut-down and turned out of doors, to be planted in an open border or beds, where they flower magnificently; the same system of management is repeated next season, and after the second blooming the old plants are destroyed.

A press of other work has prevented us from quite finishing our potting, but it all ought to be done this month, especially the larger hard-wooded plants. Smaller plants may be potted later, if it is necessary to make a choice as to which ought to be left.

The stage Pelargoniums have been cut down. The old plants have been left out of doors for the present. Before cutting them they are allowed to become quite dry at the roots, and no water is given until the wounds are healed. They bleed very much from the cut parts if these precautions are not taken. The cuttings are put-in at once, and they root best if the pots are placed on the stage of the greenhouse near the glass. The cutting-pots ought not to be watered for twenty-four hours after the cuttings are put in.

We are tying and training Chrysanthemums into a suitable shape. The shoots have a great tendency to become straggling if allowed their own way, and it is quite necessary to train the growths into position before the shoots become too hard. The plants require plenty of syringing and watering in this hot weather. Whenever aphid appears the points of the shoots are dusted with tobacco powder.

Lapageria rosea and alba eclipse in beauty all other greenhouse plants at present in flower. If the plants have been well syringed up to this time they will be clean and healthy, and it is as well to omit syringing them when they are in flower, but a moist atmosphere must be kept up in the house. Now is a good time to layer the shoots for the production of young stock. Moderately strong well-ripened young wood is the best to layer. If the work is done this month healthy well-rooted plants will be produced by this time next year. Good sandy peat is the best material to layer in.

Liliums make a good show, but the hot weather causes the flowers to fade rapidly. All decaying flowers and leaves must be removed at once, and a re-arrangement of the plants ought to be made weekly.—J. DOUGLAS.

## TRADE CATALOGUES RECEIVED.

Wm. Cutbush & Sons, The Nurseries, Highgate.—*General Bulb Catalogue.*

J. Linden, Rue de Chaume, Ghent, Belgium.—*Catalogue of Camellias, Azaleas, &c.*

Wm. Paul & Sons, The Nurseries, Waltham Cross.—*General Bulb Catalogue, with Lists of Camellias, Azaleas, &c.*

## HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

LEDBURY. August 17th. Mr. J. B. Masfield, Hon. Sec.  
NORTON, NEAR STOCKTON-ON-TEES. August 18th. Mr. C. Turner, Sec.  
MIRFIELD. August 19th. Mr. G. Senior and Mr. J. Rushforth, Hon. Secs.  
CALNE (Wilts). August 22nd. Mr. H. Blackford, Sec.  
NEWBURY. August 22nd. Mr. H. Seymour, Hon. Sec.  
BAWTRY. August 22nd. Mr. J. W. Fritchley, Hon. Sec.  
DORSET COUNTY. August 23rd (at Dorchester). Mr. A. Pope and Mr. C. Parsons, Secs.

CHEPSTOW. August 23rd. Mr. B. Thorn, Hon. Sec.  
CARSHALTON, WALLINGTON, and BEDDINGTON. August 24th. Mr. J. Baines, Leicester House, Carshalton, and Mr. W. Clark, the Nurseries, Wallington, Hon. Secs.

LARGO AND FAIRLIE. August 25th. Mr. D. G. Glen, Hon. Sec.  
SANDY. August 25th. Mr. E. T. Smith, Hon. Sec.  
SEATON BURN. August 26th. Mr. R. Richardson and Mr. W. Elliott, Secs.  
DOVER. August 29th. Messrs. E. W. Fry and C. T. Whiteley, Hon. Secs.  
CHIPPENHAM. (Cottagers' Garden Improvement Society). August 29th. Mr. Alfred Wright, Sec.

ISLE OF THANET (MARGATE). August 30th. Mr. C. D. Smith, 8, Marine Terrace, Margate, Sec.

SHIRLEY, MILLBROOK, and FREEMANTLE. August 30th. Mr. Jennings and Mr. Squibb, Hon. Secs.

POCKLINGTON. August 31st. Sec., Mr. J. E. Ross.

YARMOUTH. August 31st. Mr. S. Aldred, Hon. Sec.

THORNTON HEATH. September 1st and 2nd. Mr. W. Raines, 10, St. John's Villas, Bensham Manor Road, Thornton Heath, Hon. Sec.

MONTROSE. September 1st and 2nd. Mr. Alex. Burnett, 2, High Street, Sec.

STAMFORD. September 7th. Entries close September 2nd. Address the Hon. Secs., Stamford.

DUNDEE (International). September 7th, 8th, and 9th. Mr. W. R. McKelvie, 26, Euclid Crescent, Sec.

GLASGOW. September 12th and 13th. Mr. F. Gibb. Doughall, 167, Canning Street, Sec.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY. September 18th.

KILMARNOCK. September 14th. Mr. M. Smith, 11, King Street, Sec.

IPSWICH. September 17th. Sec., Mr. W. B. Jeffries, Henley Road, Ipswich.

NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.

LOUGHBOROUGH (Chrysanthemums and Fruit). November 21st. Mr. John West, Chapman Street, Loughborough, Sec.

## TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*King Heath*).—The "Greenhouse" does not contain the names of all plants grown in it. The "Cottage Gardeners' Dictionary" would suit you.

COVERS FOR OUR VOLS. (*H. W.*).—Cloth covers may be had from our office.

AUBICULAS (*H. C. D.*).—We are not permitted to give the address of those who do not sign their names. We can forward letters enclosed to us for the purpose, and prepaid.

GLADIOLUS LEAVES' TOPS BROWN (*F. A.*).—Deficiency of moisture at the roots is the probable cause. The scrap of plant is of a Begonia.

PANSY SEEDLING (*J. Hobbs*).—Though small we think it worth naming and sending out, for it is the blackest flower we ever saw.

VINE LEAVES DECAYING (*T. E. D.*).—We believe that deficient moisture at the roots is the cause. Water abundantly thrice a-week during dry hot weather. "Watering occasionally" is more injurious than beneficial.

CUCUMBERS BITTER (*A. Boyle*).—As yours and all your neighbours' are similarly bitter, we can only surmise that none of them have had a sufficient supply of water during this intensely hot and dry weather.

ALL-FLOWER (*E. T. M. W.*).—We do not know a plant by that name. We know All-good, All-heal, All-seed. Was not *w* omitted?

PRICKLY COMFREY (*H. W.*).—It is a perennial, known to botanists as *Symphytum aspernum*. It may be raised from seed by sowing it in the spring in drills to remain, or the seedlings to be planted out. It grows 5 feet high. It may be further propagated by dividing the roots in autumn. Each piece will grow, and they should be planted about 3 feet apart. They are quite hardy, and need no culture but weeding.

GARDEN NEAR CHESTER.—In answer to Mr. Shortt: In a simple matter of taste I thought that anyone might express an opinion, and as the matter in question seemed to me to be contrary to good taste I said so, without the least idea that I was reflecting on any one; for surely *de gustibus non disputandum*.

*tandum*, and there is nothing upon which people differ so much, and on which, therefore, difference is allowable.—D., Deal.

**HORLEY'S GREENHOUSE (J. McN.).**—We cannot state the particulars you need. It may be advertised again.

**ORNAMENTAL GRASSES AND EVERLASTINGS (Anxious Gardener).**—*Acroclonium roseum* and var. *album*, *Ammobium alatum*, a small white Everlasting; it and the two preceding being half-hardy annuals. *Helichrysum bracteatum* and var. *alba*, *H. monstrosum* album flore pleno, and the following double varieties of *H. monstrosum* flore pleno—atro-coccineum, luteum, purpureum, and roseum; *Rhodanthe maculata*, its white variety (*alba*), and *atro-sanguinea*, *R. Mangiesi*. The *Rhodanthes* are half-hardy annuals. For quantity, the best plan is to procure a "collection of double *Helichrysms* in ten varieties," they being the best, adding the *Acroclonium*, *Ammobium*, and *Rhodanthe* if you wish, but they are not nearly so profitable. Grasses are—*Agrostis nebulosa*, *A. argentea*; *Briza gracilis*, *B. maxima*; *Eragrostis elegans*, *Lasiagrostis argentea*, *Paspalum elegans*, *Piptatherum Thomasi*, and *Stipa elegantissima*.

**AIR OF VINERY (Le Grand).**—With a temperature of 92° by sun heat, whether the Grapes are colouring or ripe, we should have the air moist by watering the paths.

**MAIZE (E. Stone).**—You may continue watering as long as the stems remain green.

**GRAPES SHRIVELLING (W. C.).**—Unless they are ripe we should water copiously.

**SIDES FOR ORCHARD HOUSE (Henry Wright).**—Boards will answer for the back of the orchard house, and if you were to fix them to the interior of the house—the inside of the posts—you would have a straight face, against which you could train the trees. We should not double-board the sides and back and fill with sawdust, as that would be almost, if not fully, as expensive as a 9-inch brick wall. A double-boarded back would be considerably warmer than a single one; but in seeking warmth and durability, masonry is preferable to woodwork. We have no recollection of the heating of a small house by a metal pipe fixed into another consuming charcoal.

**ALTERNANTHERAS FOR BEDDING (C. T. H.).**—*Amena*, *magnifica*, and *amabilis* are the best.

**REDDISH-PURPLE LOBELIAS (Idem).**—The two you mention—namely, *Omen* and *Defiance*, are as good as any, to which may be added *Purple Prince*.

**ONION MAGGOT (J. L.).**—It is caused by the Onion fly (*Anthomyia ceparum*), the females of which deposit their eggs within the leaf-sheaths of the Onion close to the ground in May up to September. The eggs being hatched the grub appears which is so disastrous to the Onion crop. There is not, that we are aware, any remedy after the Onions are attacked, but a preventive is had by watering the ground with diluted ammoniacal liquor from the gas-works, one pint being allowed to six gallons of water, and applied to the ground the day before sowing the seed, giving what would be considered a fair watering—six gallons will be sufficient for 30 square yards. Gas lime applied at the time of sowing at the rate of twenty bushels per acre, or sprinkled between the rows at the rate mentioned the early part of May, or if the season be forward the end of April. The fumes given off are offensive to the fly, preventing the eggs being deposited. Hot water, we fear, to destroy grubs inside an Onion must be so high in temperature as to destroy bulbs which are not attacked as well as those which are.

**PLANTING VINES (A Novice).**—We prefer to have part inside and part outside borders for Vines, in all cases planting inside, having the inside border the full width of the house, and the outside at least half, or better two-thirds, the width of the house; 15 feet will answer for the width of a lean-to house, but we should prefer to have it 18 to 20 feet. The Vines should be planted 4 feet 6 inches apart, though for Hamburgs and the non-Muscat or late Grapes, 4 feet will answer. The border should consist of the top 3 inches of a pasture taken off with its turf where the soil is a good hazel loam, light rather than heavy, and cut up rather roughly—of that ten parts, one part mortar rubbish from an old building, one part charcoal, one part sand or freestone, in lumps from a walnut up to a cricket ball, and one part half-inch bones, the whole to be thoroughly incorporated and put together in a dry state, allowing one-third the depth for setting. The kinds most suitable are—*Early*: \*Black Hamburg, \*Foster's White Seedling, Mill Hill Hamburg, and Buckland Sweetwater, \*White Frontignan succeeding admirably. *Medium*: Black Prince, Muscat Trouveren, \*Frankenthal, Black Muscat (Muscat Hamburg), \*Madresfield Court, and \*Waltham Cross, \*Golden Queen being excellent. *Late*: \*Black Alicante, Burchardt's Prince, Mrs. Pince, \*Lady Downe's Seedling, Gros Guillaume (Barbarossa), \*Muscat of Alexandria, \*Calabrian Raisin, Trebiano, and \*White Tokay. As you may only wish for a few kinds, those marked with an asterisk are the most suitable. Our "Vine Manual," 2s. 7½d., and "Greenhouse Manual," 10d., in both cases free by post from our office, will aid you.

**REPOTTING AZALEAS AND CAMELLIAS (Sam).**—Azaleas are best potted when the new growth is being made in spring, or so soon as the flowering is past. The present is a good time to repot Camellias, the buds being set. We should not repot the Azaleas until spring, but the Camellias we advise to be potted at once; but it is an evil to give them frequent pottings. Every second year is often enough to pot young plants, and every third or fourth year for old plants. The pots should be well drained, and an inch of space be allowed all around the old ball of soil. Any old soil coming away freely with a pointed stick from amongst the roots should be removed, but be careful not to break the roots. Sandy fibrous peat broken up moderately fine is a proper compost for Azaleas; and three parts fibrous light loam and a part sandy fibrous peat is a proper compost for Camellias.

**CULTURE AND PROPAGATION OF LANTANAS (A Subscriber).**—They are half-hardy shrubs, requiring to be kept dry in winter and safe from frost. In spring the shoots should be cut-in to within an inch of the old wood, and being moderately watered they will soon start into growth. When the shoots are an inch long turn them out of the pots, removing most of the old soil, and returning to the same or a smaller size of pot, one that will conveniently hold the roots. Keep rather close and shaded, sprinkling overhead twice daily until the potting is recovered from, then afford a light airy position near the glass. When the roots show around the sides of the pot, and before they become closely matted, shift into pots 2 inches larger in diameter, watering carefully for a time; and when the roots are working freely in the fresh soil water copiously, shifting into pots 2 inches larger, watering alternately with liquid manure when the pots are filled with roots. Regulate the shoots as they advance, securing to neat stakes. Fibrous loam with a fourth of leaf soil or well-decayed manure is a suitable compost. Cuttings of the young shoots taken off in spring or any time during summer strike freely in

a gentle bottom heat shaded from sun. The cuttings should have two joints and the growing point.

**ROSES MILDEWED (Idem).**—The Rose leaves are mildewed. Syringe them on the under side of the leaves, as well as the upper, with a solution of soft soap, 2 ozs. to the gallon of water. The cause of this and other parasites attacking plants is not known. Repeat the application if necessary, and give a good watering to the roots, mulching over the surface with short manure. We do not recognise the plant by the leaf and flower sent. It was too much crushed and imperfect for identification.

**NAMES OF FRUITS (S.).**—It is either Early Moorpark or Hem-kerk; probably the former. It is difficult to name Apricots from a single specimen of the fruit alone. (Knutsford).—All the numbers were off and mixed.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### OUR BANK HOLIDAY.

"Do come and see my chickens, and tell me what I am to do with them, for my grass is all dried-up, and my runs look like miniature deserts." This invitation came to us in a letter from a friend, and so we determined to go down and advise, although we knew we had nothing fresh to recommend or to suggest. We little, however, thought of what we were doing when we by telegram accepted that invitation, for when we arrived at the London station where our train was to start from we realised for the first time that it was the vigil of the bank holiday. Never can we forget the scene of indescribable confusion. It seemed as if London had en masse determined to set forth, like a mighty army, for Ramegate and Margate. Men and women by troops all laden with parcels of all imaginable sizes and shapes. Hampers, baskets, bundles, bird cages, fish baskets, champagne cases, ice, portmanteaus, bonnet boxes, and hundreds of other packages all seemed massed together in dire confusion. Women with babies were trying to pull some particular basket or package from a heap; youths and boys were in everyone's way, with fishing-rods and butterfly nets, as if they expected piscatorial excursions at Pegwell Bay or entomological walks over St. Lawrence's Fields. We stood by our hatbox, portmanteau, and a basket of birds which we were taking with us, and warded off passengers and their goods. We had a long time to wait, but wait we did patiently, wondering why parents would all take their babies, and others their parrots and dogs, for such a short visit on such a day. Just as we returned to our *impedimenta*, after a brief absence, we heard a crash, and a box of the size of a small house—containing we should think the family plate and linen and effects of a good large family—was plumped down on the top of our own well-beloved basket of birds. We rushed to the rescue, and dragged the remains from under the monster. The inmates were alive and apparently not damaged, but the basket—not a stick was whole in it, and it appeared as if it had been extracted from the maw of a boa constrictor. We determined never if possible to travel on such a day again, and if we had ever to break that resolution never to bring any of our live stock with us. In the north, where two or three shows would be going on, and where the people almost surpass the southerners in their craze for going out holiday-keeping, we could but feel compassion for those exhibitors who were sending about dogs or birds unattended. But at last we got off, and after sundry stops at all sorts of places where we never should have stopped, after innumerable jerks and jostles, after travelling in a carriage with seven people on a side where there should only have been four, we arrived at our friend's station, and at once betook ourselves to the yards whose runs were described as like "miniature deserts."

We certainly did find them in a bad way. They were scorched to the shade of the now-fashionable cream colour, and not even a dandelion leaf or a plantain stalk broke the colour of the surface. Well, we spent that Saturday evening in soaking the grass from one end to the other. There were three of us at it; one drew the water, another carried the pails, and the third poured it on the parched strands. We deluged it from one end to the other, and worked at it till dark. Then we went in and looked over a pack of schedules of forthcoming shows, marvelling at the stupidity of many committees and the terrible ignorance many of them showed by their prospectuses, and then we talked over the late disqualifications in Spanish and the peculiarities some judges are displaying who ought to know better, until bedtime. The next morning our evening's work amply repaid us; the runs looked so much fresher and brighter, and the birds were all at work digging, and rooting, and scratching, instead of standing listlessly idle as they had been before doing for day after day, and learning the abominable habit of feather-eating. We recommended lettuces to our friend, who was as yet young in the fancy, and threw in a bushel nearly of plants which had gone to seed; and the way the leaves, and stalks even, disappeared before us showed plainly that the birds had been pining away for green food. On the Monday morning we set to work and limewashed all the houses inside, and scattered some ears of corn about the runs for the birds to pick out the grains, and we stuck large branches of spruce, firs, and holly about the runs

to make shade, and tried to put things generally on a better footing. When Monday evening came, and we had once more to go through the tortures of travelling home again with the Rams-gate and Margate pilgrims, our unpleasant journey and disagreeable reminiscences were almost forgotten when we thought that we had found on arrival a poultry-yard stocked with valuable birds in a very bad state, and had left them not only already better in appearance, but had given directions for their future welfare, so that their owner might have reason to remember that he had benefited by "our bank holiday."—W.

## HOW I BEGAN BY KEEPING FOWLS AND ENDED BY THE FOWLS KEEPING ME.

"No eggs again for breakfast?" said my father. He was a stern and angry man, my father, and his quasi interrogation as he surveyed the table made my mother jump.

My mother was a mild placid woman; and, as I said before, she jumped. My father repeated the remark; and this time my mother replied with a deprecatory "No."

"I'll keep no more fowls," said my father. "Eating their heads off with barley and all sorts of things, and never a spring chicken nor so much as an egg for breakfast when you want it. I'll have all their necks stretched to-day, and make an end of it!"

My father was a man of few words, and my mother did not care to dispute the point. His son (meaning myself) was a bit of a pet, and knew it.

"Give 'em to me, father."

"Go on with your bread and butter," said my mother. However, I knew how to coax, and in the end had my way.

My father agreed to allow me the bits of leavings from the scullery and half a bushel of corn once a-week during the next three months, and he was to buy my eggs and chickens of me at a fair market valuation; and after three months I was to keep them myself. On these terms I became the possessor of six hens—one Dorking, two with a cross of Game in them, and three common barndoor fowls, with a barndoor cock, and at once commenced operations.

Adjoining the back kitchen we had a good-sized yard, about 24 feet by 20, unpaved, with a bit of a shed in one corner, half of which was closed and filled with roosts as a hen house, and an old plane tree in another corner which in summer gave a pleasant shade. Here it was that I stood and surveyed my newly-acquired property with a pride such as Alexander never felt in his conquered worlds when he wept that there were no more to subdue.

I began by digging-up half-way along one side of the sunny wall of the yard a strip of earth about a yard wide, and out of my pocket money at a cost of about 2s., assisted by Tom the gardener's boy, fenced it in with wire to prevent the fowls from encroaching; and here I planted quite a hedge of sunflowers. My fence was quite a temporary affair, for as soon as the seeds should have sprung up and the plants grown to about a foot high it was my intention to remove it. By favour of the groom I got a barrowful of horse litter and dung, which I shot in the corner near the base of the plane tree; and for half-a-crown I purchased a large barrowload of good gravel, which I disposed in the middle of the yard. A row of orange boxes filled with clean straw in the fowl house, each with a chalk egg in it to tempt the sitter, made capital nests; and now I was prepared to commence the campaign.

The servants could not make the hens lay, and had been content to throw down so much corn every day and let the fowls shift for themselves. It was my turn to see what I could do, and, boy as I was, I had my own ideas on the subject.

In the morning before going to school I used to feed my flock with a handful of barley mixed with the scraps of bread and leavings from the breakfast table, not forgetting the broken egg shells, rind of bacon, and other unconsidered trifles, but which to me were invaluable, the whole well cut and crumbled up into a homogeneous mass, and so distributed. After one o'clock dinner I used to pay them another visit, this time with the remains of the potatoes and other vegetables (not such as the cook would have saved, but simply the leavings on the plates), which I used to rewarm in a saucepan over the fire with a little gravy or sour milk that might be standing in the milk-jug. At five o'clock another handful of barley, or, if any scraps were lying about (and there were generally some), a mess similar to that at mid-day. Occasionally this would be varied by the addition of a little bran; and in winter I used to sop bread or potatoes in warm beer which I saved from my dinner, and which I found my fowls devour with extraordinary avidity. After one of these feasts I was almost always rewarded with an extra lay of eggs.

I had almost forgotten to mention that a few lumps of rough chalk and a piece of bay salt thrown casually down in the yard were immensely appreciated by my feathered friends.

Every week I turned over my gravel heap and my manure heap, so as to afford fresh materials for my fowls to scratch in, and at long intervals renewed them with half a barrow or so of

fresh stuff. These precautions I regarded as indispensable to the welfare of the poultry.

In the winter they might be seen scratching and clucking over the warm manure heap, or in summer dusting themselves in the clean gravel, with all the luxuriousness of confirmed Sybarites.

Before long the results of my treatment began to show themselves in a regular supply of new-laid eggs, and when two of the hens wanted to sit I purchased new-laid eggs of the Polish, Spanish, and Dorking breeds to serve as the objects of their maternal experiences. I thus improved my stock with fowls reared from eggs of the finest breeds that could possibly be procured.

Whenever a fowl was seen to be ailing or moping I always caught it, and after administering a couple of peppercorns or some other simple remedy, kept it in a hamper by the kitchen fire, a treatment which almost invariably proved successful. Once a hen had some obstruction in her crop, which would not digest, and I actually opened the crop with a lancet, cleaned it out, and sewed it up again; the hen not only surviving the operation, but thriving well after. But the ailments of fowls opens out too wide a subject; for the present I want to confine myself to the prescribed limits of my narrative.

When a brood of chickens was expected to be hatched I was always in attendance, and a most skilful accoucheur I came to be—removing the chickens one by one from under the mother, and placing them in a warm flannel near the fire, with a little chopped hard-boiled egg and Embden grits, after giving each a peppercorn by way of commencement.

When all were hatched and the added eggs thrown away, the mother was put under a coop placed over a sack for warmth, and for the first few nights placed indoors, till the chicks began to feel their legs and run about.

After a few days Dame Partlet was allowed to take her family under her own charge, and seldom did I lose by the permission, as cats were far more wary when the hen was at large than when confined beneath a coop and her young ones far away from her protecting wings.

In each brood there was naturally a larger proportion of cock than hen birds; these after a certain age I used to weed out, preserving the pullets and putting-up the young cockerels to fatten for the table. My process of fattening was to confine the young birds in coops, and feed them upon oatmeal brashed in sour milk, and served-up scalding. A little salt contributes to the fattening process materially. If they showed any tendency to pine I would change their food, or even give them a few days' run of their legs, a course which used to put the fat again upon their bones, and leave them free to recommence the orthodox fattening process.

Now for the details. My first six months, I am free to confess, were conducted at a loss as nearly as I can remember, as follows:—

	£	s.	d.
Laying-out the ground—Fencing .....	0	2	0
Gravel .....	0	8	6
Manure .....	0	2	6
Barley, 26 weeks at 1s. per week .....	1	6	0
Extras .....	0	5	0
	£1	19	0

Any returns during that period I will write off as lost. During this time, however, my sunflowers had come to maturity and flowered. My readers may not be aware that the seeds of the sunflower are the finest stimulant for poultry in existence, and the avidity with which fowls will scratch round the roots of the sunflower's tall stalks and pick up the seeds which fall from their wide open flowers is something perfectly surprising to behold.

Now for my gains. In the next six months I had doubled the number of my laying hens, and substituted a fine Game cock for the old barndoor fowl which I already had.

During the same period I had averaged four eggs a-day, which I sold to my father at 1d. a-piece—and I had had four broods of fine chicks—say in all twenty-eight young birds—of which six were now laying, and the rest (twenty-two) had been fattened and sold as fine birds at Christmas for 3s. and 3s. 6d. a-piece (I did not charge my father full market prices "*bien entendu*," but this by the way):—

	£	s.	d.
182 days at 4d. per day .....	3	0	8
22 fowls at 3s. each .....	3	6	0
	£6	6	8
Deduct barley for 26 weeks .....	1	6	0
Extras .....	1	0	0
Cost of coops, &c. ....	1	0	0
Loss on previous six months .....	1	19	0
Total .....	£5	5	0
Nett gain .....	£1	1	8

In the next year I had more than doubled my number of

laying hens, all of good breeds, and without any outlay, and my returns were more than doubled. My expenses at the same time were less, and even with a decreasing tendency. I sent one or two birds of my rearing to a poultry show, and won not only a £10 prize, but sold my birds at fancy prices. My eggs and fowls I now began to send to the tradesmen round about after providing for the home demands, and especially during autumn and winter, realised high prices for my produce. I soon had a bit of money in the savings' bank, and when I was forced to go into the world and work for my living I could no longer devote my time to poultry breeding. I sold thirty-six fowls of various fine breeds at an average of £2 a-piece, taking the bad with the good, and retired with a very decent sum at my back, as the result of my innocent request at the breakfast table a few years before—"Give 'em to me, father."

A great many details of fowl management I have necessarily been compelled to skip over owing to the limits of my space, but on these, if I may be permitted and my readers would like to hear them, I can enlarge more fully at another time.—(Housekeeper.)

## POULTRY AND BIRD NEWS.

WE are sorry to hear that the celebrated establishment of French poultry belonging to the late Mr. W. Dring of Faversham is entirely broken up. We learn that Mrs. Dring has abandoned all intention of continuing to exhibit, and has sold all the Crêves to Mr. Burrell, and the Houdans and La Flèche to Mrs. Vallance. We hope sincerely that the mantle of our deceased friend will descend upon the new owners.

The Leghorn Club is certainly at work, and that too very vigorously. We find they have arranged for classes for both the varieties at Weymouth, Bath, Middleton, Oxford, Newcastle, Cirencester, Alexandra Palace, Swindon, Shrewsbury, Carmarthen, Aylesbury, and for other shows. We hear, too, they propose to publish a Standard of Excellence for the breed; and if so, we shall hope to have a copy sent to us, when we will report upon it.

Portsmouth seems to get deeper into disgrace, for no prizes seem to be paid, or are many of the letters answered. We hope exhibitors will all combine and enforce the payment of the prize money. We do not think they will hesitate to do so, for the statement of the Committee on the first page of the schedule as regards payment of prize money is very plain. Many, too, will remember the grand banquet which was going on while exhibitors were endeavouring fruitlessly to get the awards, and will feel if there was money forthcoming for that, so must it be found to pay the prize money.

We would urge once more exhibitors and breeders of the less-cultivated breeds to apply at once to Mr. J. King, 111, St. Aldate's, Oxford, the Hon. Secretary of the Poultry Show, as the Committee are desirous of making their schedule as pleasing as possible to all, and only want support and promise of help to put such breeds as Sultans, Minorcas, White Malays, Peruvian Ducks, Booted Bantams, and such like on the same level in prize money as Brahmas and Cochins. We cannot help remembering that Oxford has played a most important part in the present prosperity of Silkies, Leghorns, Black Cochins, &c., for in many cases they provided classes and cups for these breeds when they had previously had none before at most exhibitions—in fact Silkies made their *début* here with a class to themselves. Pigeons this year are, we learn, to be on the single-bird system, and the Committee are equally ready here to make new classes where promises of help are given.

The Ipswich and Eastern Counties Society's Show, to be held in September, is the Society's first exhibition. The Society is in no way connected with the Show held at Ipswich in December.

## CASTLE EDEN SHOW OF POULTRY, &c.

THE annual Show of the Castle Eden District Agricultural Society was held at Houghton-le-Spring on the 8th inst. Unfortunately the Show had not been sufficiently advertised to insure a good entry, and it would be well for the Council to see to this point for another season.

Among the few entries, however, we noticed some capital birds in Mr. Procter's winning *Cochins* and Mr. Carver's stud, the latter gentleman carrying off the points prize, and in the chicken class we found by far the best Cochin pullets we have seen this year—in fact, so good was one that we do not expect to see her surpassed at any show. These were in the open field, but the *Pigeons*, of which there was a good entry, were placed in a very neat tent. In Carriers, first was a good Black hen and second a Dun cock; a Black cock was very highly commended. In Pouters, Whites in splendid condition won; the remainder very good, but out of feather. Tumblers, though good, were not so well shown. First a Yellow Agate, and second a Kite very good in head properties. Jacobins a grand class of thirteen, and mostly Reds, and many in nice order. In Turbits, first was

Blue and second Yellow, two nice specimens. Fantails a pretty fair lot. Owls good indeed, the first and second White African and also the very highly commended. Some good English had to put up with poorer fare. The Variety class was an extra good one; first a Grey Frillback, second a Blondinette, and third Yellow Barb. Many others were noticed. Mr. Beckwith won the points prize.

POULTRY.—DORINGS.—1, T. P. Carver. COCHINS.—1 and 2, G. H. Procter. BRAHMAS.—1, T. P. Carver. 2, J. N. Lawson. HAMBURGHS.—Golden-pencilled.—1 and 2, T. P. Carver. Golden-spangled.—1 and 2, T. P. Carver. Silver-spangled.—1, J. Hudson. 2, G. Alderson. GAME.—Black-breasted or other Reds.—1, W. Bearpark. 2, C. Taylor. Extra 2, W. Allan. BANTAMS.—Game.—1, T. Putnam. 2, J. T. Winter. Any other variety.—1 and 2, T. P. Carver. DUCKS.—Rouen.—1, T. P. Carver. 2, Miss J. Scott. ANY BREED.—Chickens.—1, G. H. Procter. 2, J. Hudson. 3, W. Bearpark. *vhc*, W. Henderson. GESE.—1, T. P. Carver. 2, H. Porters. *vhc*, Miss M. Brown. TURKEYS.—1, T. P. Carver. ANY OTHER VARIETY.—1, T. P. Carver. 2, J. Hudson. SELLING CLASS.—1, J. Hudson. 2, W. Allan. Point prize.—T. P. Carver. PIGEONS.—CARRIER.—1, 2, and *vhc*, W. Beckwith. POUTER.—1 and 2, R. A. Nicholson. *vhc*, R. A. Nicholson, W. Beckwith. TUMBLER.—1, 2, and *vhc*, W. Beckwith. JACOBIN.—1, G. Alderson. 2, J. Young. Young, W. G. Moody. RABBITS.—LOP-EARED.—1, W. Simpson. 2, W. Allan. ANY OTHER VARIETY.—1, Miss Sutherland. 2, R. Laverick.

JUDGE.—Mr. E. Hutton, Padsey.

## IDLE SHOW OF POULTRY, &c.

THE first Show of the Idle Agricultural Society was held on the 12th inst, and the weather being fine it proved a great success. The poultry, Pigeons, and Rabbits were shown in Turner's pens, arranged on three sides of the field. In poultry there were 107 entries, in Pigeons 223, and in Rabbits 27. The staff of assistants was far too small for the amount of work, and the consequence was that the Secretary himself had to put up the cards, and this was not done till a late hour.

In poultry *Spanish* were first on the list, and these were a nice lot, and the awards well made. *Game* (old) were very good, the cup and first going to Piles, the cock most perfect; second being Black Reds, very good; but we were sorry to see Mr. Cock's splendid Brown Reds had to put up with a high commendation. *Cochins* and *Brahmas* very good, the latter especially. *Hamburghs* were in grand order throughout, and well placed. *Game Bantams* good, and in the Variety class Whites were first and Blacks second. The cup for the best pen of poultry was given to Mr. Beldon's Silver Polish. Young poultry turned up well in all classes, the *Game* and *Hamburghs* being particularly good.

In *Pigeons* there were two point cups, and most of the great guns were in competition for them. In the first section—viz., that of standard birds, the contest was keen between Messrs. Fulton and Baker, the latter winning by about seven points; and in the second section it was said to be a set between Mr. Entwistle and Mr. Ellis, Antwerps being the leading feature with these two gentlemen. Carrier cocks had nine entries, and all noticed. A grand young Black first; not as heavy as Mr. Baker's well-known Black, which was second, but more to our liking in style of wattle and carriage; both extraordinary birds. Hens both Duns, of grand properties in both head and beak; the rest all noticed, as also the whole of the Pouters in both classes. Pouters, cocks.—First a White, in splendid show; second a Red, not in the best feather; very highly commended a grand Blue. Hens.—First a Blue hen, grand in style and shape; a little gay. Second White, a splendid bird, but a little thick in girth. Tumblers (Almonds).—First a well-broken cock; second a hen, which lost in little considering the sex; the rest all good. Tumblers.—First a Yellow Wholefeather; second a Kite, capital in head properties. Barbs.—First a well-known hen, and second a cock; all Blacks, and a very good class. Dragons, Blue or Silver, a poor class, but winners very good; first Silver and second Blue. Owls (Foreign) the best class in the Show, and an extra second awarded; first and second White, and extra second a Blue hen. English Owls also a fair lot; first Blue and second Silver. Turbits.—First and second Silvers; the hen first. In Jacobins we scarcely think a better lot could be got together. The winners were Reds. Fantails not a good entry, and Balds and Beards (Long-faces), and other Long-faces as well, but there were some good birds in the list. Antwerps, Short-faces.—Mr. Entwistle fairly cleared the ground, the rest, though good, being nowhere with them in both classes. Long-faced cocks.—First a well-known Red Chequer, a splendid bird; and second a Dun, dull in colour, but otherwise a good bird. Long-faced hens.—First Blue Chequer, good in all points but marking; second a Dun. Medium-faced cocks.—First and second Silver Duns; and in hens—first Silver and second Red Chequer. In young birds of the Short-faced variety first and second were very correct, and some good ones were also noticed, but many were mediums. Any other variety of this year produced an extraordinary class, mostly of Long-faced birds, the prizes falling to the lot of Red Chequers which will some day make a stir in the Antwerp classes. The Variety class contained many very good birds, first going to a Black Trumpeter and second to a Nun, both nearly perfect.

In Rabbits there were but four classes and no extra prizes;

but we hope to see a better provision for another year. Lops were a very good class; a handsome Black-and-white doe, 224 by 4½ was placed first; the second a Fawn-and-white doe, 22 by 4½, good in style, bad eye, and not well marked. This reverses the Alford award, which we contend was quite wrong. Some were almost eaten-up with fleas; but worst of all was Messrs. Schofield and Barrett's splendid Black doe, which was first at Alford, and was ill then, but in this case was in so offensive a state as to be totally unfit to handle, the virulent matter springing out of the ear on attempting to measure it. Himalayans only three; first very good old, and second a promising young one. Silver-Greys were a capital class; but all were not placed at the same advantage, the light being shaded in some, and the full sunlight upon the others. The first was one of the nearest perfect-coated we ever saw, but too dark on the nose, and slightly so on the forehead, but this must be a winner; second a doe, beautifully even, but rather too light and out of shape, but better than at Bramley; pen 427 (Golithy) seemed to skulk, and did not look well, but was very highly commended; 429 (Ball) a splendid Rabbit, but also dark on the nose. In the Variety class first was a Silver-Cream, and second a Belgian Hare; the first a grand one.

### A FRIENDLY GANDER.

I HAVE seen and heard of people making pets of all sorts of living creatures besides Cowper's hares and the rats of a prison, all of which have in return exhibited more or less intelligence; but never till the other day did I think there was any sense in a Goose, or rather gander.

I was visiting at Mr. M——'s, in a small village, who has among other stock on his farm a flock of Geese. One of these, for some reason best known to itself, prefers to lead a solitary life, rarely joining its companions, but has formed a strong attachment to my friend Mr. M——, following him about when going over the land, and waiting outside when he calls at any house in the village. The gander leads the way generally, looking round to see if he is going right, and that my friend and his two fox terriers are following.—S.

### ARTIFICIAL HONEY SUPERS.

I TAKE up my pen to call in question the value of a proceeding recommended by Mr. Pettigrew in a recent number. For the production of the finest super honey he recommends your readers to drive their bees, and then cut out the best part of comb a brood skep can be expected to yield, and so fill the handy little American supers, which are to be placed on certain hives; and these, fed with the contents of the discoloured or bred-in combs of the broken-up hives for the completion of the supers, and under the gloss of fresh cell-covers retouched, are to be palmed off on an unsuspecting public as super honey. But I much question if such a procedure is either seemly, or, were the manufacturing process generally known, would the supers be very saleable. I am a little doubtful whether our little favourites

would readily be made parties to the transaction, judging from the rapidity with which the contents of severed combs of their own tops left on for attachment disappear into the stock hive.

Be this as it may, the principle of feeding to obtain or complete supers is most reprehensible, whether the article employed be sugar syrup pure and simple or the run contents of stock hives, which of necessity contain the surplus stored-up sugar-syrup of bypast springs and autumns with all the many honeys mixed, the varied pollens and juice of the squeezed grubs adding piquancy to the flavour, and possibly perfumed in addition with the decaying foul-brood fungi, or yet as a last resort the brisk effervescing contents of the cheap foreign honey cask. To escape such nauseous mixtures sold as run honey, &c., frequently thickened with the coarsest brown sugar, the wealthier classes—at least with us in the north—cheerfully pay about double the price for the finest super honey, believing that in so doing they obtain as they ought the pure exudation of the current season's flowers, untouched by human hands, and stored in a separate compartment of the hive distinct from all breeding contamination; and nothing will go more to hurt honey exhibitions and the sale of such supers than the belief getting abroad that they are got up artificially—mere shoddy after all. —A RENFREWSHIRE BEE-KEEPER.

### HOW TO FILL THE APIARY.

THE time has now arrived when cottagers begin to suffocate bees in brimstone pits with a view to take their honey. Many persons know no other way of obtaining the honey, and they stubbornly follow the customs and practices of defunct generations. A clergyman living in the neighbourhood of Salisbury informs me that he has offered his bee-keeping parishioners to restore them the honey and hive, and 1s. per swarm besides, if they will let him take the bees and keep them alive instead of their consigning them to the brimstone pit. They have a dogged resolve not to have their antique ways improved, and therefore he does not expect his offer will be universally received. This gentleman has only to show them a better and more profitable mode of managing bees to induce them to abandon their antique ways. Some years ago I could buy swarms in this locality in August and September for 2s. 6d. each if I drove them; now the bee-keepers here will not sell, neither will they destroy their bees. I would readily buy now at 2s. 6d. per swarm, or say 1s. per lb. of bees. A good swarm in September weighs above 4 lbs. In being driven a good swarm will take more than 1 lb. of honey with it; hence it would be no gain to cottagers to get 1s. each for driven swarms. Those who wish to fill their apiary with good stocks, and those who wish to teach by example, will do well to purchase the condemned bees of the cottagers near them, say at 1s. per lb. of bees, for apart from example they are worth that price.

In creating a stock of hives, or in filling an apiary with condemned bees, about 5 lbs. of them with a young queen should be put into a 16-inch hive and fed vigorously for fourteen days or thereabouts. From 15 to 20 lbs. of sugar boiled in eighteen or twenty pints of pure water is enough for such a swarm and hive. By the time the syrup is all given the hive will be nearly filled with combs, and these combs will be fairly filled with brood. Stocks thus created are unsurpassed for excellence. The combs are young and clean, without a cell of foul brood and without a superabundance of bee-bread. The population is numerous and healthy, with an ample supply of wholesome food. In weighing a stock thus made it will be found that the weight of the water has been lost in the building of the combs and the keeping of the bees during the process—that is to say, 30 lbs. of syrup will enable the bees to fill their hive with combs and store up about 15 lbs. of food for the winter and spring months. Of course if larger swarms and hives are used more sugar-syrup will be required. Sugar-made stocks are highly valued, and I earnestly hope that many readers will fill their apiaries with bees that would otherwise be doomed to the brimstone hole. Condemned bees are well worth 1s. per lb. to strengthen their stocks by being united to them.—A. PETTIGREW.

### HONEY RECIPES.—No. 1.

THE British Bee-keeper's Association last year offered prizes for liqueurs and sweetmeats made from honey. The competition was not great, but we had some score or so bottles of honey wine, more than half of which—sent by Mr. J. S. Wood from Denmark—being unaccompanied by the recipes, were not for competition; had they been, the prize-winner must have trembled for his laurels, for some of them were prime. I have reason to know it, for Mr. Wood kindly presented me with his exhibits. The recipe given for the liqueur to which the prize was awarded is as follows:—

*Recipe for Sack Mead.*—To each gallon of water add 6 lbs. of honey and also the white of an egg and the shell broken up. Boil this mixture until the scum has all been cleared off, then add 1 oz. of hops to the gallon, and boil slowly for one hour. Strain

away the hops, and when new-milkwarm add a small quantity of yeast on a toast; let it stand a couple of days, and then put it into a barrel, which should only have been used previously, if at all, for white wine. Skim off any yeast which rises before being put into the barrel. Let the mead stand two years before bottling, and then when bottled it will keep for any length of time, and the colour will deepen with age.

For making wine or liqueurs honey is much more used on the continent of Europe than in Great Britain. Mr. Wood tells me that at the honey show at Copenhagen there were exhibited some thousands of bottles.—JOHN HUNTER.

### OUR LETTER BOX.

**CAUSE OF CROOKED BREASTS (W. C. C.).**—You have propounded a difficult question. It is certain that some breeds are never crooked-breasted, and that others always are. Some fowls like yours roost on the ground, and their breasts are in the shape of the letter S, others will roost on a walking-stick and their breasts will remain as straight as a line. We believe the defect to be hereditary. We once tried an experiment by shutting-up two crooked-breasted hens and keeping their produce separate. We deprived them of perches, and allowed them always to roost on the floor of the house which we kept scrupulously clean and dry, but they had crooked breasts. To the present day we have not a chicken of this year that has seen the inside of a poultry house, nor will they till long nights and colder weather make it advisable. They have no crooked breasts. We believe they may be attributed to two causes—weakness of constitution, and undue growth due to bad and stimulating feeding. The weights you quote are far beyond the ordinary weights of chickens of the age you name, and can be attained only by such care as you describe. But in birds as in human beings, there is such a thing as undue growth consequent on overfeeding. We imagine this is your case. Handle your birds through at once, keep for your stock only the straight-breasted. Let their house be without perch, and feed on moderate food—ground oats slaked with milk, maize at times, some large sods of grass cut with plenty of fresh earth, and household scraps, which you should diminish daily till they do without them. Keep the crooked-breasted for layers, or kill them for table purposes. You should have told us the food you employ.

**PIGEON WITH INFLAMED LUNGS (E. B. T.).**—We have during the last thirty-five years or so had birds occasionally so afflicted, but never one was cured, nor do we believe there is any cure. Surgical remedies there are for surgical cases. The diseases outside a Pigeon, such as wing disease, bad eyes, &c., we have cured, but we disbelieve in any cure of what is inside the bird. A medical friend of ours once experimented with calomel and purgatives on a pugnacious cock Pigeon, and do what he would the bird was as full of fight and strength as ever. After a dose overnight which would have compelled a man to keep his bed, the bird was as lively and pugnacious the next morning as ever. A warm loft without draught, good food, water daily changed, strict cleanliness, and few birds, with no odd cock, and Pigeons are healthy enough unless hereditarily diseased. Thus we have lost this spring two stranger birds, one of canker, the other of "going light," and we have no doubt they would have propagated diseased birds, hence they are best gone. Be careful as to strains you buy. You speak of "books not giving good information on Pigeon diseases." Their authors are right, for we do not think there are any cures. Perhaps the homoeopaths will take up the Pigeon and try their skill. Mr. Fulton's new book has a chapter on the diseases of Pigeons, and his experience has been very great, but his remedies we have as yet had no opportunity of testing, so of them we cannot speak.

**FOOD FOR BULLFINCHES—MUTILATION OF FEATHERS (A. B. G.).**—Those who keep Bullfinches in London have not the facility of obtaining berries and buds of various kinds as food equal to those in rural districts, and as your request is for the "best green food for Bullfinches in London," we advise you to give your birds occasionally watercress, grass seeds, small salad, and a bit of apple, in addition to the steeped rape seed and hemp. Furnish the latter sparingly, as it is so heating, and affects Bullfinches more than other kinds of cage birds. Many instances are known of blindness or change in colour of plumage and a general wasting away occurring through a free use of hemp. Exceptions still may be found to the contrary, and much depends upon the birds' constitutions and varied and confined temperature. We certainly think birds must possess extraordinary appetites when, as you ask the question, "they begin to eat each other's feathers." Apparently they may appear to be so doing. If a new quill feather should be ruthlessly drawn from a wing or tail, Bullfinches and other small cage birds will extract from the stump a moisture which one might imagine was a savoury treat to them, to judge from the pains they bestow to "chavell" up the quill end. It is a very common occurrence for birds to pluck and destroy each other's feathers in confinement, and the habit once acquired can only be effectually prevented by separating the birds. Many old birds (Canaries for instance) will begin to mutilate their young as soon almost as they leave their nests, when the budding tail quills are fully charged with moisture. Birds also acquire this destructive habit to each other when the plumage is out of order or any of the feathers are disarranged, especially during the moulting sickness. We have ourselves had an instance of feather-mutilation within the past few days, that of a Mule (a pied one not to be despised either) having its flight feathers curled (with the constant pulling at them with the beak of another Mule) as effectually as though done with a hairdresser's curling iron. Our remedy to straighten such feathers is to dip them in hot water for half a minute and draw them betwixt the thumb and finger, afterwards to let the birds have the benefit of a "fly" cage where they can freely bathe. Birds when limited to space are more apt to disfigure each other's feathers.

**UNITING SWARMS (T. Watts).**—It is not necessary to catch the old queen when uniting swarms unless for some reason you should wish to preserve her life. We presume that in the contest for sovereignty, which must take place sooner or later when the queens come across each other after recovery from the panic consequent on their violent expulsion from their chosen homes, that "the weakest goes to the wall." If so, as is reasonably probable, you would gain nothing by hunting for and destroying the old queen, and old queens are not always less vigorous than young ones. In your case, doubtless, the rule has held good, and the strongest of the five queens remains mistress of your hive. We do not anticipate any loss in the further scheme you have in view.

**MARRIOTT'S HIVE (Triceps).**—Your swarm of June 1st in this hive seems to be doing well. No doubt they had killed off their drones before the late splendid weather set in. Their being busy and noisy at night indicates pro-

sperty. You may give them the wooden hive you speak of, but they will hardly make use of. We should prefer eking the super.

**MOVING HIVES TO THE MOORS (F. D.).**—The nearer bees are placed to their pasture the more honey will they gather; but at half a mile distant from a good field of heather they will collect large stores of it, weather permitting. Bees find and work on good pasture a mile distant from their homes.

**COMBS MELTED (Smallwood).**—The fact that the combs of your hive have fallen down with honey running out and the bees clustering outside of your hive is proof that it has not been sufficiently protected from the rays of the sun during the late very hot weather. We are sorry you have not had confidence and courage enough to put the bees into a fresh hive and take the honey at the time. In doing it now you will probably find an unsightly mess of smothered bees and broken combs inside. First get a bit of old fustian cloth or old cotton rags, rolled together like a candle, and fire it at one end to smoke as much as possible but not to blaze, and blow the smoke on the clusters outside and brush them all into an empty hive; then blow the smoke into the hive and turn it up. If all the combs are on the board lift the combs singly and brush the bees into the hive beside those that were outside. Of course you will remove the super before you turn up the hive. With plenty of smoke and a little courage any novice could do this. There will be found much loss in this breakdown, even if the honey has not been taken by other bees in your neighbourhood. The sooner you take what honey you can get, and set your bees to work in another hive, the better it will be both for you and them.

### METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

### REMARKS.

- 9th.—A brilliant day, but intensely hot. [day.  
10th.—A very fine and bright day, and very much cooler than the preceding  
11th.—Fine morning; a most delightful day—bright and sunny, but not hot.  
12th.—Another splendid day, very warm, but a nice breeze; rather storm-like about 7 P.M.  
13th.—Very fine and very hot morning, temperature 81° in shade at 9.20 A.M.; intensely hot all-day.  
14th.—Hazy morning, and fearfully hot all day, no movement in the air till the evening, when it looked cloudy and storm-like.  
15th.—Another hazy and hot morning, but soon very bright and as hot as yesterday, cloudy and a breeze between 4 and 5 P.M., with several peals of thunder between then and six, and slight sprinkle of rain, but not enough to be measured.

Mean temperature at 9 A.M. nearly 8° above that of last week, the mean max. 10°, mean min. 3°, and underground 4°, the temperature at 1 foot below the surface having exceeded 70°. The air remarkably dry, as shown by the great difference between the dry and wet bulb thermometers, now all these excesses have arisen from the intense heat of the last four days.—G. J. SYMONS.

### COVENT GARDEN MARKET.—August 16.

THE soft fruit being all finished the market has settled down into a steady sort of trade, and all classes of goods are fetching fair prices. Good Kent Filberts are now to be had.

From observations taken near London during forty-three years, the average day temperature of the week is 72.8°; and its night temperature 48.6°.

THE PROSPECTIVE SCARCITY OF VEGETABLES.  
SPINACH.

OWING to the extreme heat and long-continued drought vegetables are likely to be unusually scarce during the ensuing winter and spring. In some districts the crops of Kale, &c., could not be planted at the right time, and the plants have since made little or no progress, and what little there are left of them are half devoured by caterpillars and other marauders which are incident to a dry season. Especially in the vicinity of

large towns and populous cities will the scarcity, and consequent dearness, of vegetables be greatly felt, and it becomes a matter of importance as to what can at this late season be provided to eke out the scanty supply. Advice has been seasonably given to plant Cabbages freely, but long before the earliest-sown Cabbages can be ready for use the lack of vegetables will have become a great inconvenience.

Owing to the quick ripening of many crops—Pears, Beans, Potatoes, &c.—vacant ground is provided, and the question arises, How can a portion of such ground be most profitably turned to account? Many would doubtless plant large breadths of Coleworts, but unfortunately it is difficult to find the plants. Where they can be had they should be planted freely as soon as rain falls, for assuredly would stout plants planted during the present month yield valuable produce at a time when it cannot fail to be serviceable. Plants thus late in the season need not be planted wider than 9 inches to a foot apart, according to their size. The earth is now warmed by the many days, almost weeks, of unclouded sun, and when heavy showers fall it will steam like a hotbed, and the crops will grow rapidly. Plant Coleworts, therefore, where plants can be obtained, and plant them freely. Failing a supply of these plants any of the Kales now lingering in the seed beds would, if planted similarly closely together, probably prove extremely useful.

Many may imagine that it is "too late" to plant plants of this nature: so it is if they are expected to attain to their full size, but we must remember that if they only attain to half size they may be most valuable, and if planted at the rate of nine plants to a square yard the ground will probably be found to have been profitably occupied. During the extremely hot summer of 1868 gardeners were in much the same state that they are now, and winter vegetables had scarcely made any progress at the corresponding period of the year. In September the rains fell, and a good gardener, whom I need not further mention, had every plant of whatever kind belonging to the Brassica family planted thickly on vacant ground. I am afraid that the men whose duty it was to do the work did it reluctantly, and that allusions the reverse of complimentary were made in reference to him who ordered the work to be done. A long mild autumn followed and was succeeded by a comparatively mild winter, and the vegetable supply mainly produced

by the scrubby plants planted in September was sufficient for all purposes, while in the surrounding neighbourhood there was little short of famine in the land. I may as well place on record that simple and useful lesson which was then taught me—teaching which I have since turned to account during other dry seasons. Do not be frightened by the little words "too late," or by the small unprofitable-looking plants dragging out an apparently miserable existence in the seed beds; but, on the contrary, plant quickly when the rains fall, and plant thickly, and mayhap a dripping autumn and a mild winter may contribute to a valuable supply of "green stuff."

But in many cases plants cannot be had, and recourse must then be had to seed-sowing. Large breadths sown with Turnips, sown thinly, or the plants thinned quickly, would in all likelihood yield useful produce in due time, the use of which would enable the choicer vegetables to be preserved for special purposes. Turnip and Swede "tops" are not to be despised at a time when little beyond root crops can be used for everyday table purposes. Such "tops" often afford cuttings throughout the winter, and in the earliest days of spring give many valuable basketfuls, making the vegetable boy smile, and the cook to go so far as to inquire kindly after the health of the gardener. Do not, therefore, despise plain Turnips, but if "green crops" are scarce and ground is plentiful sow seed on the first opportunity when it is likely to grow freely, and in due time the tops of the Turnips, and possibly the bottoms too, may be as highly valued as the flowers in the greenhouse.

Another crop which will, if seed be sown at this period of the year, produce a large supply of "green stuff" during winter and spring is Spinach. This valuable old vegetable has been grown in Europe for upwards of five hundred years, being included, it is said, in a list of vegetables consumed by the monks on fast days in 1351. Spinach is a productive and healthy vegetable which would possibly be more valued if less common and more difficult to cultivate; it is, however, "miffy" enough in some places, and the crop of winter Spinach has not unfrequently been a source of trouble to many a good gardener. The plants canker, shrivel, or decay—indeed do anything but grow in some gardens, but fortunately in most ordinarily good soils Spinach grows luxuriantly.

For summer cultivation the soil for Spinach cannot well be too rich and moist, but for winter supply manuring of the ground may easily be overdone. It is also possible that errors have been made in sowing the seed to produce the winter's crop in sheltered places, for it is almost certain that the crop would stand better in the ordinary soil of an open field than in the heavily manured soil of a sheltered garden. It is thus also with Cabbages and Broccolis and most large-foliaged crops of a succulent nature. Such crops need a full sweep of autumn air to render them hardy from infancy, and it is seldom that they will then succumb to the vicissitudes of winter.

For some years I have been able to sow Spinach in an open field as well as in a sheltered garden, and in no one

instance have I known the garden crop to endure the winter so well as the field crop. Not only has such been the case, but I have found that the Round or summer Spinach, which is usually considered to be tender, will survive the winter better in an exposed field than will the Prickly or winter Spinach in the lighter richer soil of a walled garden. That information was gained after a dry season and in occupying vacant ground in August and September with such quick-growing crops that were likely to be useful in eking out the prospective scarcity of the winter and spring supply of vegetables. All the vacant garden ground was occupied, and the remnant of the Spinach seed was sown in the field as an experiment, or perhaps, what is more probable, as a freak of fancy. Thus I was surprised to find the Round nearly as hardy as the Prickly Spinach, and the former in the field proved decidedly better than the latter in the garden. Need I say that I have since relied on exposed places and ordinary field soil for my main supply of winter Spinach? Since adopting that practice I have never had a failure.

A great source of failure with Spinach in winter is the moisture hanging round the necks of the plants and which cannot drain away freely. Another evil, and withal a common one, is, in the first place, sowing the seeds too thickly, and then not thinning out the plants sufficiently early. The plants should be thinned, if possible, before they touch each other; then the plants which are to remain are totally undisturbed. If thinning is too long postponed and the permanent plants suffer any disturbance or displacement, and are suddenly deprived of the shelter and support of surrounding plants, then the crop of winter Spinach is almost certain to "go off." If the plants are not thinned out early it is better not to thin them at all: and in all cases it is advisable to take pains to procure good seed and to sow it thinly.

But while Spinach is a vegetable which is in demand almost every day in the year in most large establishments, and the failure of the crop is consequently a source of great inconvenience, yet it is not popular and relied on as a staple vegetable—that is, other vegetables are generally preferred to it; but when we can gather basketfuls of Spinach at a time when the "other vegetables" are not forthcoming, it is surprising how we learn to value that which under other circumstances would be almost despised. It is found also, after considerable experience, that the more Spinach is consumed the more it grows in the estimation of the consumers. When once the palate has become "educated" to its use it is looked upon, as is the gardener who produces it, in a season of vegetable famine, with no small amount of respect.

Therefore is it that the free sowing of vacant ground with Spinach at this period of the year is urged as worthy the consideration of those having large families to supply with vegetables, and an unpleasantly small store (as many must necessarily have) to meet that demand. It may be sown on rich ground or poor, on ground sheltered or exposed; and if more happens to be produced than is required, no great loss will ensue, or probably no loss at all, for the digging-in of the crop is a capital manure for other crops succeeding.—R. FISH'S PUEBLO.

### COVERING SURFACES IN FERNERIES.

ALTHOUGH I am about to recommend *Nertera depressa* for a purpose devoted to which it must lack two of the "three prime essentials" mentioned by "W. B. J." (page 23)—namely, "coolness" and "light," I by no means wish your correspondent to conclude that I approach the subject in a deprecatory spirit. There is no question but that the mode of culture detailed by "W. B. J." is the correct one, but we not unfrequently make a plant serve a purpose in a much higher temperature than its natural requirements demand. The very common and no less very useful *Lycopod*, *Selaginella denticulata*, is very nearly hardy, and yet it grows nowhere so luxuriantly as in a stove temperature. The Maiden-hair Fern (*Adiantum Capillus-Veneris*) is a native plant, but is quite at home in a warm house. The curious Liverwort, *Marchantia polymorpha*, grows on wet rocks icebound in winter for weeks, yet it thrives apace on the saturated rocks in a stove fernery. *Ficus repens*, another hardy plant, attains no such luxuriance in a greenhouse or outdoors as in a stove. We have it in a sort of cavern-like entrance to a fernery, and it makes no effort to reach to the light, and grows slowly. It is thus both interesting and instructive to observe what a persistence some plants have of life and of adapting themselves to circumstances.

In ferneries bare walls and rocks are more or less objection-

able: hence plants of dwarf, dense, yet rapid growth, maintaining an evergreen carpet or covering at all seasons, meet a ready acceptance. Wire trellises fixed an inch or two from walls stuffed with green moss, backed with compost and planted with Ferns and *Lycopods*, have, it must be admitted, a pleasing effect for a time, but soon require renewing. A better plan is in building the wall to let some of the stones jut out a few inches and have the face uneven, so as to form ledges even only an inch or two in width. Upon these ledges can be introduced small plants of *Adiantum Capillus-Veneris*, which only require sufficient soil to maintain them in position, for they will speedily put out their roots over the surface of the wall if it be kept moist. This *Adiantum* is one of the finest of plants for clothing rocks or walls.

If there are any ledges on a level with the eye (or a broad one may be formed by leaving off the inner course of stone just before the wall receives the wall plate) we have only to introduce some chipping of stone for drainage, and put on some peat or old cocoa-nut refuse to have a position for *Nertera depressa*, the plants being divided into as many pieces as wished, from the size of the thumb nail up to that of one or more inches square. All it wants after planting is to be kept moist, never allowing it to lack moisture. It may also be introduced upon any of the ledges on the wall surface, but does best near the glass. In stove or greenhouse temperature it is quite at home—one of the finest, densest, and dwarfest surface-covering plants that I am acquainted with. In heat its insignificant yellowish blossoms appear in early spring, and are succeeded by its orange bead-like berries, spangling amid the moss-like foliage.

Other subjects for wall-covering ledges on walls are the neat *Selaginella apoda*, truly a gem, and the pretty *S. helvetica*. Amongst Ferns with creeping stems suitable for wall or rock-covering may be enumerated *Pleopeltis stigmatica*, the very similar *P. squamula*, *Campyloneuron cespitosum*, *Goniophlebium piloselloides*, *G. vacciniifolium*, *G. lepidopteris* (se-pultum), and *Niphobolus rupestris*, all of very neat growth, and such as will clothe or dot a wall with verdure in a fitting manner. In order to take off the flatness a few stones may project rather more than others, and upon these we may have *Nephrolepis tuberosa*, its fronds coming out in a particularly graceful manner, its only fault being that of outgrowing other plants; it should therefore be well kept in hand. Some of the *Davallias*, as *D. pentaphylla*, *D. decora*, and *D. solida*, are good on such projections, and no doubt many others, none being finer than *Nephrolepis davallioides*, but it requires room and a stove temperature. The *Stenochlanas* (also requiring stove heat), from their climbing Ivy-like habit are very useful for covering wall surfaces; but what I particularly wish to note is the rapidity with which any uneven surface—even a perpendicular wall, is covered when there are hollows or projections forming resting places for spores and ultimately plants.

There is really nothing so pleasing in a fernery as the rising of numberless seedlings on the rocky surfaces. Cork imitations of rockwork are preferable to cement. Fantastic and grotesque indeed are imitations of rockwork in cement, but no Fern spore will ever vegetate upon it. There is no objection to artificial rock when it is intended to appear as natural rock cropping up here and there either in the massive or boulder formations; but there is a decided disadvantage in such imitations when the rockwork is intended as representing the plants in a state of nature. In nature plants find in the rock they spring from the elements of their existence; but to use cement upon the surface of rockwork is to seal it against plant life. Boulder formation is not an uncommon imitation in rockwork. It is the most simple of all, as we have only to form sloping undulating ground and scatter it with boulder rock; in some places congregated masses, others isolated, with large boulders partly imbedded appearing as parts of a mass beneath the surface. In most cases boulder rock should form, as it does in nature, the sides and hollows of dells. It would be difficult to give any particular directions for constructing rockwork, but I certainly consider all imitations should be taken from the natural types. No two kinds of stone should be used in the same rock or any of its parts exteriorly, and due regard being had to the requirements of culture.

Rockwork formed of "cobblestones" cannot be too severely censured. The want of better materials may have given rise to the imitation of rock in cement, the sites for plants being thereby reduced, so as to give a like proportion of positions for plants as that afforded by natural rocks, but with the regularity of culture instead of the picturesque irregularity of

nature. Sites for plants will, of course, be the aim of the rockwork constructor. Recesses, crevices, ledges, and these so disposed as not to show a preponderance of rock or of verdure throughout, but imposing masses of both, rock preponderating in some parts, verdure in others, the latter being mostly in nature located in the recesses. As a rule the lesser forms of Ferns only are in nature associated with rock in the mass, the taller forms being present near the boulders, whilst the most stately are not associated with rock in any form. In planting rockwork plants are frequently placed in positions in which they cannot show themselves advantageously, and far too much grotesqueness is attempted, intricate ugliness supplanting Nature's simplicity.

I must refer once again to the covering of wall surfaces or rocks. I have already noted the covering of them with Ferns, we will now do it with *Ficus repens*; and I strongly advise the wall to be built rough, as it will certainly appear the better when covered with the *Ficus* and the ultimate planting of its surface with Ferns, for the *Ficus* forms by its branches and roots (aërial) the finest of all holders of compost, it being only necessary after the wall is well covered to make an opening with the hand, parting the *Ficus* from the wall, and introduce soil; but I put in cocoa-nut refuse and turn out a plant from a pot into the hole in the *Ficus*, and firming the cocoa refuse about the plant. Any kind of Fern almost will grow in such positions, but those with drooping fronds, as *Goniophlebium subauriculatum*, *Adiantums*, *Aspleniums*, and *Platyneriums* appear best. These or others appearing upon or from the green coppery mantle of the *Ficus* have, I think, a much better effect than even a Fern-covered wall, exhibiting as it does, under the best of circumstances, too much wall, the *Ficus* being a complete covering. It is hardly necessary to add that soil must be provided for the plants to grow in—i.e., the *Ficus*. I use sandy peat with a little turfy loam, and the wall surface is kept constantly moist.—G. ABBEY.

[*Ficus repens* is not usually considered a "hardy" plant. It is a stove plant, but we have known its sprays to protrude from the inside to the outside of a house and pass through at least one winter uninjured. It is a native of the East Indies.—EDS.]

#### ROSES, &c.—SYRINGING.

I was taken to task by one of your correspondents some little time back for having made too general a condemnation of the Briar stock, and quoting his own experience of success. Now, if I remember rightly, the conditions under which the Roses on the Briar which he mentioned as being successful, were exactly those under which the Briar has a chance of succeeding—that is, not as standards, but as stocks to Roses trained against the wall and allowed to grow freely. I have never said that the Briar will not succeed on certain favourable soils and under certain conditions; but I have always maintained that the system of growing Roses as standard bushes, be they tall or be they dwarf, is one which militates against the production of really good Roses. The whole system of pruning and training is against the true nature of the Rose, which is always inclined to throw up strong shoots from the base. Look at a Dog Rose in a hedge, and you will find that every year it throws up suckers from the roots. Look at all Roses on their own roots or on Manetti stocks properly planted, they will continually push up strong shoots from near the ground. These are the shoots which produce the best blooms, and which should be taken most care of by cutting away old wood and encouraging free growth; and this is precisely what cannot be done with standards grown to mop heads. Standards well covered with Roses may be pretty while in bloom, but for the greatest part of the year they are unsightly. I am not going to repeat now what I have said before about the mortality among standards on the Briar, but I do venture to repeat my warnings against planting standard Roses in small gardens. No doubt there are some soils more suited for the Dog Rose stock than for the Manetti, as all heavy clays and unctuous loams. But in these soils Roses might be grown as dwarfs on the seedling Briar with the crown planted either below or on the level of the ground, or they may be budded on the Dog Rose grown from cuttings. Any way, as a rule, if the Briar is to be used, it is far better to use either the seedling Briar or cuttings, or grafting Roses on suckers of the Briar. I have so often seen standard Roses completely destroyed by frost or burnt up with dry weather, that I rarely now see a standard in Yorkshire with a decent Rose on it; but I do not on that

account wish to condemn it as a stock when properly used for dwarf Roses on strong soils.

I see "WILD SAVAGE'S" experience of his brother's Roses in the north agrees with mine. Always prune late. My Roses were not pruned this year till the last week in April, and I never had on the whole better blooms. The cold winds of March and April with severe frosts had so injured all the young spring shoots that I had in nine cases out of ten to cut back to dormant buds. Had I pruned back early the new growth must have suffered. As I do not exhibit I do not go through the agony of mind that "WILD SAVAGE" (how long will he continue his *soubriquet*?) and others do about having blooms ready for the principal shows, and I do not mind having them late, and this year I hardly had any Roses till the first week in July. My experience of this year's season with several of the Roses he mentions has been quite similar to his. Charles Lefebvre has been seldom good, nor has Alfred Colomb been as good as usual. I have had some wonderfully fine blooms of Thomas Methven, a sort originally much recommended by the late Mr. Perry, a very good judge, and I never before knew how fine a Rose it could be, two or three blooms I cut this year being almost the best alike in form and colour and fullness of petal of any Roses I have seen this year. Edouard Morren, too, I must confess, even against my prejudices, has been good, and M. Boncenne, which is rarely really good with me, has been very fine. Other sorts very good this year have been M. Marie Rady, Baroness Rothschild, La France, Maurice Bernardin, Xavier Olibo, Boule d'Or, Marguerite de St. Amand, Marquise de Castellane, Etienne Levet, F. Michelon, Fisher Holmes, Duke of Wellington, &c. I do not much believe in either the syringe or the water-pot for Roses in the open borders. Give plenty of mulching and manure during winter and spring, and, unless the season is very exceptional, there will be no trouble with green fly and no necessity for the water-cart, unless it is with Roses trained to walls.

While on the subject of water I venture to say that Mr. Abbey's warning against the use of the syringe for Grapes, Peaches, &c., and amongst stove and greenhouse plants, seems to me very fraught with danger. I see so many more plants injured from not using the syringe enough than from the free use of it, that, though he may be correct in theory in saying that leaves in a state of nature do not receive rain underneath, yet he must remember there is many a heavy rain that comes in driving showers and washes the under part of the leaf as well as the upper. I do not believe in the bloom of Grapes or Peaches being injured by pure rain water. I syringed a bunch of perfectly ripe Grapes with a jet d'eau a few days ago as hard as I could force it within a few inches of the bunch, and did not bring off the bloom. I do not mean to say that plants may not be injured by useless syringing; but I am convinced that far more plants which are growing in houses much exposed to the heat of the sun are spoilt through neglect of the syringe than by the overuse of it, and that it is a most valuable remedy to keep down the attacks of red spider, thrips, green fly, and other insect pests. I am not and never was a believer in the idea that leaves could suck in moisture through their breathing pores, as I believe that all carbonic acid is absorbed through the roots, and that during light the growth is matured and the carbon fixed when oxygen is given off, and during the night the leaves evaporate moisture and carbonic acid; but syringing checks evaporation and keeps both the upper and under sides of the leaves clean and free to carry out their proper functions, and I am consequently convinced that syringing the under sides of leaves will do no harm even though in nature the upper surface may be most exposed to the action of rain; but as plants in houses are under artificial treatment, the rain has also to be artificially applied, and so long as leaves are not bruised or broken I do not believe soft water from a syringe will hurt them, unless a house is made too damp and cold by too constant a use of it.—C. P. P.

#### GRAPES CRACKING.

GRAPES seldom crack or split before they begin to ripen. An excessive flow of sap is generally supposed to be the cause of the disaster. This may be correct in exceptional instances, but I think as a general rule cracking is the result of a damp close atmosphere more than anything else. It is pretty well known how a shower of rain will cause Gooseberries to burst, and moisture appears to act the same way on Grapes.

I saw a large vineyard a short time ago which was chiefly

planted with Black Hamburgs. The fruit was about quarter ripe, and a few nights previous they were well syringed for what was intended to be the last time. The ventilators were closed for the night as usual, and next morning nearly the half of the berries on every bunch were burst. The atmospheric dampness was the only difference to what they had been accustomed from the time they started to colour. I have since been told of one or two other cases of the same kind, and I think it may safely be inferred that an over-damp atmosphere is one of the chief causes of Grapes cracking.

Vines may be syringed after the fruit commences colouring, and where insects are plentiful it is necessary to do this; but when such has to be done great care should be taken to leave both top and bottom ventilators open a little, so that a current of air may pass through the house until it is quite dry. Many Grape-growers are in the habit of leaving the ventilators open to a certain extent night and day, and if this plan was more adopted there would be fewer cases of Grapes cracking.—J. MUIR.

### THE TIMBER SUPPLY—TREE PLANTING.

THE articles which have been published under the above heading relate to matters of considerable importance. One cannot read of the wanton destruction of valuable timber without regret, let such waste occur where it may. That our American friends, with their vast timber resources, are recognising the necessity of checking the destruction of timber is a circumstance from which we may profit; for if in England we have no such corresponding waste, the waste of previous generations is both seen and felt, and the dearth following the scarcity of English timber is unfortunately too well established.

In many of the rural districts of England timber has become so scarce that tradesmen and farmers have to travel many miles to "wood sales," and the eagerness which they display at these gatherings to become possessed of the different "lots," demonstrates in a most conclusive manner that timber is regarded by those best able to judge as a scarce and valuable commodity.

I cannot say that I read with pleasure the account of the waste of timber going on in America which appeared on pp. 140-141, but I read it with interest, and I was gratified to notice the editorial remark—that "the planting of timber trees should be encouraged."

Certainly tree-planting should be encouraged in England, where felling trees has been carried on to such an extent that in some districts there are scarcely any trees left standing, and no young plantations are being established. Apart from the timber supply the clearing the land of trees is an unwise policy, for there is little doubt but that such denudation is fraught with disadvantages. I have been informed that since large districts in India and America have been denuded of trees that the atmosphere has become greatly changed, and that long periods of drought have succeeded. A clergyman in England some years ago entered an earnest protest against the destruction of the only large wood in his locality, on the ground that the rainfall of the district would thereby be so greatly diminished as to be detrimental to the prosperity of agriculture. That district is now one of the driest in England, and is notorious for the tracks of thunderstorms which, almost with the regularity of clockwork, pass it by on either side.

Woods and trees serve also an important purpose, in affording both shelter and shade—shelter from cutting boisterous winds, and shade for the panting herds and flocks from the fierce rays of the summer's sun. It is only those dwelling in woodless districts who can adequately appreciate the value of shade, and considerable expense has been incurred in providing it in an artificial manner after the error was perceived of removing the natural shade—the trees. There are agricultural "reformers" who are so ardent that the sight of a tree nills them with horror, but were they transported to wholly treeless districts their propensity for felling and "stubbing" would probably become modified.

But while some districts have been almost entirely denuded of useful timber trees by felling of the old and neglecting to plant the young, others there are which are heavily wooded, and yet the wood is in a great measure unprofitable. Woods are preserved in many instances, not for the value of the trees, but for the "game" which they encourage, and for fear of "disturbing the game" there must be little or no felling of trees, and the timber on hundreds of acres of land is in a measure rotting on the ground. That is a great waste and a great error. Woods and plantations are frequently so managed

—or rather mismanaged—that they are a great loss to both the owners of them and the inhabitants of the district. Owners have a right to enjoy their own—to their game and their woods, but one would imagine that they would enjoy it the more were it profitable, as all wooded property might be, and have "game" into the bargain.

Many years of experience tell me that wooded property if rightly managed is as lucrative to an owner as the acres which he "lets" to his tenants for agricultural purposes. I am intimately acquainted with an estate, the miles of woods of which were for generations profitless to the owner, but which for the last twenty-five years, under different management, have been "self-supporting;" and much more than that, for the additional labour which has been employed has been beneficial to many families, the timber that has been produced has been of great value to the trading community, the owner has derived an income from land that was formerly a loss to him, and "game" is as plentiful as ever.

In these woods there have been annual fellings of trees—thorough clearances—and annual plantings—that is, that for every large timber tree that has been cut down certainly twenty small trees have been planted. For twenty and more years from 50,000 to 150,000 trees have been planted yearly. These have been principally Larches, which have been planted about 4 feet apart as nurses to the Oaks, which are to be the permanent trees. The liberal planting of Larches is profitable. In a very few years thinning must commence; the first thinnings selling freely as stakes, the second as stouter fence wood, the third as small poles, and so on according to the growth of the trees. I have known more profit derived from a given acreage of Larch over a period of thirty years than has been obtained from any other portion of an estate which was rented by agricultural tenants. The planting of trees, therefore, should be encouraged, both as a profitable investment on the part of a proprietor, and also as conferring benefit in many ways to a district.

There are thousands of acres of "scrubby" woods and profitless wastes which could be utilised by the planting of trees freely, and especially Larches; and on soils wherein Larch will not grow Scotch Firs will flourish, be the soil ever so poor.

Our timber supplies are becoming so exhausted that it is well that attention is being directed to the subject, for if the whole question is thoroughly examined it can hardly fail to result in the more general and systematic planting of trees, and the converting of almost useless wastes into profitable tracks. If the matter of timber preservation and the necessity of planting is of importance in America—and such appears to be the case—it is of far greater importance in England, where the scarcity of wood has caused it to rise 100 per cent. in value during the last half century.—A FORESTER.

### A HARDY PERENNIAL FLOWER BORDER.

A BORDER or bed of hardy flowers that is thoroughly well managed is one of the most attractive features of a garden not merely at a stated season but throughout the year. In the very depth of winter it has its snowy masses of Hellebore (Christmas Rose), and quaintly formed succulents, among which spring-up the Crocus and Snowdrop—heralds of spring, while it is yet far off—Erica carnea with its thousands of deep pink bells, the Gentians and Anemones in all their charming varieties, while a host of other gems come crowding upon us as the year advances.

There is a very prevalent idea that when once the flowers are planted in such a border very little subsequent care or attention is necessary. Nothing can be more erroneous than such an impression, leading as it does to neglect that is as hurtful as unintentional. When flowers for all seasons are planted, the fact of itself implies that frequent attention to staking, tying, pruning, thinning of crowded growth, is necessary; also if the soil is a deep, sound, and tolerably rich loam, as it ought to be, this involves much lifting, division, and re-arrangement—all apparently trifling matters, but yet they cannot be ignored if we wish to preserve our plants in full health and vigour. I am very well aware that flowers even in profusion may be found in borders that have remained undisturbed for years, but all such borders that have come under my notice have been very far below the standard of perfection which it is possible to approach. We want less roughness, crowding, and confusion, and more of trimness and individuality. Now individuality or tone is easily imparted. Take for example a border sufficiently wide to admit of a bold

belt of Hollyhocks along the back, with an occasional specimen of *Fuchsia Riccartoni* standing-out in the centre, with other specimens between but kept well apart, such as *Tritomas*, the autumn-flowering *Asters* (*Michaelmas Daisy*), the tall-growing *Campanulas*, and masses of *Lathyrus*. In front of these and among them arranged with strict regard to height and habit of growth, we would have specimens of such kinds as are bold enough to produce an effect singly like the *Phloxes*, *Pentstemons*, *Aquilegias*, *Antirrhinums*, *Spiræas*, *Veronicas*, and *Tradescantias*. There should also be clumps and little colonies of other plants of more lowly growth, like the *Genms*, *Anemones*, *Gentianas*, *Violas*, *Primulas*, and many others, keeping each plant or group sufficiently far apart from the others to admit of its full development. Does not this arrangement convey to the mind a picture that is as desirable as it is uncommon—a picture, too, that admits of almost endless variation? Bulbs, spring and summer annuals, are all available for our border, as they are certainly desirable.

"J. S. W." has a border 36 yards long by 2 wide, used hitherto for ordinary spring and summer flowering plants, which he wishes to convert into a hardy perennial flower border. To render this gay next season solely with hardy flowers, three or four times the number would be required that there would eventually be space for. It would, therefore, be better to plant only a certain quantity in the first instance, filling the intermediate spaces with bulbs and annuals for a few seasons, adding to the permanent occupants annually as may appear necessary.

The following list contains only sorts of known merit, those which embrace many varieties, as *Phloxes*, *Pyrethrums*, *Pentstemons*, *Carnations*, *Primulas*. *Dianthus*es should be planted sparingly at first, and gradually added to as individual taste may induce a preference for either genus.

<i>Dielytra spectabilis</i>	<i>Papaver orientale</i>
<i>Pyrethrums</i> in variety	<i>Anemones</i> in variety
<i>Dodecatheon elegans</i>	<i>Aster versicolor</i>
<i>Gentiana acutis</i>	<i>eriodoides</i>
<i>pneumonanthe</i>	<i>bessarabicus</i>
<i>asclepiadea</i>	<i>Delphiniums</i> in variety
<i>verna</i>	<i>Arum italicum</i>
<i>Trillium grandiflorum</i>	<i>Ranunculus aconitifolius</i>
<i>Geum coccineum</i>	<i>Iris germanica</i>
<i>Ponies</i> in variety	<i>susiana</i>
<i>Helianthemums</i> in variety	<i>reticulata</i>
<i>Campanulas</i> in variety	<i>Alyssum saxatile</i>
<i>Helleborus niger</i>	<i>Hollyhocks</i>
<i>Spiræa palmata</i>	<i>Veronica spicata</i>
<i>Erica carnea</i>	<i>gentianoides</i>
<i>Dianthus</i> es in variety	<i>Teucrium</i>
<i>Aquilegias</i> in variety	<i>Potentillas</i>
<i>Nephele oncorum</i>	<i>Oenothera macrocarpa</i>
<i>Pentstemons</i> in variety	<i>taraxacifolia</i>
<i>Statice latifolia</i>	<i>gigantea</i>
<i>Tritoma Uvaria</i>	<i>Hesperis matronalis</i>
<i>Antirrhinums</i> in variety	<i>Cheranthus Marshallii</i>
<i>Tradescantia virginica</i>	<i>Lathyrus latifolius albus</i>
<i>Phloxes</i> in variety	<i>rotundifolius</i>

—EDWARD LUCKHURST.

### PRUNING ORCHARD TREES.

THERE are many Apple orchards which can be depended on for a crop of fruit only once in every two years, and the crop then is generally so great numerically that the individual fruits are small and inferior in quality, the trees not having sufficient strength to bring the superabundant crop to perfection; and yet if the trees had only been treated in a manner which almost any ordinary countryman can be made to understand, a fair crop of fine fruit in a bad season and a heavy crop of superior fruit in a good fruit season would be produced. The way I have adopted, and which has produced these good results, is as follows:—

My trees had for a few previous years been neglected, and their tops had in consequence become much crowded with thin and imperfectly developed branches; the leaves were very small, and the trees generally much blighted. A man and an active boy, who could climb well and knew how to use a saw, were set to work during sharp weather in the winter when ordinary work had to be suspended. The man stood below with a long pole and pointed out to the boy in the tree the exact spot at which the branches which appeared to be in the way should be cut off. At least half the tops of the trees were in this way thinned out, and plenty of room was made amongst them for the free circulation of light and air. Sufficient firewood was cut out to pay for the work done. The trees after the operation spread over as much space as before, but only having half the number of branches to support it followed as a matter

of course that each branch was able to derive double the amount of nutriment from the roots that it had been receiving before, and therefore produced larger and healthier leaves, larger and healthier flowers more able to withstand the effects of spring frosts, and larger, healthier, and better fruit. An orchard treated thus may even in unfavourable seasons be depended upon for producing a fair crop of fine fruit, and in a favourable season a very heavy crop of superior fruit, and this will last till the trees succumb to natural decay from old age, or from exceptional causes which will of course sometimes arise.

The almost general failure in the Apple crop on large trees this season might have been avoided had people not been afraid of making an intelligent use of the knife.—J. E. EWING, *Royal Norfolk Nurseries, Norwich.*

### LANTANAS.

For some years past these attractive plants would seem to have been somewhat neglected. They used to be included in most gardens where collections of plants for the greenhouse and flower garden were cultivated; but latterly it has only been in a few places where justice has been done to them. Yet, although *Lantanas* are not extensively cultivated, better varieties than ever have been raised, and as soon as the merits of these varieties are sufficiently known their cultivation will almost certainly follow.

Especially as bedding plants in hot seasons and in dry localities are *Lantanas* valuable. They resist the effects of extreme heat better than most bedding plants, even better than do *Geraniums*, for during the present tropical season *Geranium* beds have a literally "seedy" appearance, their trusses being mostly trusses of seed pods. *Verbenas* are also dried out, and *Lobelias* are transient, but *Lantanas* are fresh and luxuriant, having foliage intensely green and flowers in profusion and in great variety of colour. The plants, too, are quite free from insects without the aid of doctoring, syringing, or fumigating—no small advantage in a season like the present, when most plants have had a full share of insect or grub enemies to struggle against.

The effect of a bed of mixed varieties of *Lantanas* may not be fully as gay as a bed of *Verbenas*, but it is equally pleasing, and colours are represented in the former which are not found in the latter. The glossy freshness of the foliage of *Lantanas* is also such as cannot be rivalled by *Verbenas*.

*Lantanas* grow freely in ordinary garden soil. It should not, however, be too rich and the plants have too much water if a profusion of trusses are desired. They are also admirable for cultivation in pots for conservatory decoration in summer. The plants may be prepared in cold frames, or may be plunged in ashes in a warm position in the open air. No plants are more easy to cultivate, and perhaps the only point in which they are not generally admired is their peculiar perfume. For hot gardens, vases, and sunny sites grow *Lantanas*. The following are good varieties:—

*Magenta King*.—Colour purplish scarlet; a free bloomer, and of dwarf habit. Suitable for pots or beds.

*Don Calmet*.—Pink, changing to yellow; a very free bloomer, and good yet dwarf grower. An attractive variety.

*Favourita*.—Brownish yellow, changing to scarlet, suffused with purple. A distinct and effective variety.

*Victoire*.—Pure white, with a lemon eye; a good grower and free bloomer.

*La Manula*.—Rosy pink, deepening in colour towards the centre of the trusses, and changing to yellow at their margin. Free and attractive.

*Mons. Chauvière*.—Red, changing to scarlet, with a yellow centre. A gay and attractive variety.

The abovenamed half-dozen varieties are worthy of cultivation in pots, and they are also excellent for bedding purposes, continuing in bloom for a great length of time. I have found these plants very valuable, and especially during the present hot and dry season.—A SURREY GARDENER.

### NEW BEDDING PLANTS.

In taking notes of bedding plants this year I can strongly recommend to those who have not tried it *Ageratum* *Countess of Stair*. It is somewhat lighter and much softer and brighter than *Imperial Dwarf*, a very free bloomer, compact grower, and with good stiff truss thrown well up above the foliage. It is decidedly the best *Ageratum* I have yet seen. *Lobelia* *Alpha* has quite borne out the high opinion I formed of it.

Among new sorts of Geraniums on trial in beds the Rev. T. F. Atkinson (Pearson), a crimson, very large both in flower and truss, has been striking. John Gibbons, a bright scarlet, very fine. Both are somewhat strong growers. Mrs. J. F. Fenn, in the way of Amaranth, a deep lilac pink, has had magnificent trusses. It is a very good match for Mrs. Musters or Amaranth. Sir H. Stanhope is an improvement on General Outram. Miss Strachan (Pearson), a salmon, has proved good in beds as well as in pots; and two beautiful bright pinks, Lucy Bosworth and Lady Byron, have both done well in beds, though I think they are better for pots. Lady Stanhope as a variety of the Lady Middleton type is very superior both for pots and beds. Among others which I need not stop to specify which have been and are exceedingly effective are Frank Miles, Augusta Miles, Mrs. Lowe, Violet Hill (both the last as good as ever), Bayard, Mrs. Vincent, General Outram, Mrs. Huish, Lady Kirkland, Arthur Pearson; and among tricolors William Sanday and Macbeth stand pre-eminent. I will add a few more notes on this subject shortly.—C. P. PEACH.

## VEGETABLES AND FRUIT AT SWANLEY.—No. 2.

*Continued from page 140.*

A NOTICE of the soil's productions of this fertile district would be incomplete without some allusion to the vegetable crops—the Potatoes and Peas—and to the fruit plantations, especially of Raspberries and Strawberries, which are extensively and ably cultivated.

The fields are not small enclosures and to be compared with the size of large gardens—indeed they are scarcely enclosures at all, for there are but few dividing fences, and where there are barriers there are fewer gates, and the fields are apparently open to all. An aspect of freedom pervades the district, and restrictions as to "right of way" do not appear to be appreciated if we may take as an example the liberty which had been taken with a gate on which the owner had had printed in large letters—"No Thoroughfare," and from which the "no" had been carefully obliterated, converting the inscription into a general invitation for all to enter who chose to do so.

The fields vary from one to five hundred acres, and far as the eye can reach the undulated surface is clothed with Potatoes and fruit plantations, and here and there a corn field by way of a change. To such an extent is fruit cultivated in this district that not less than five hundred acres in one parish alone (Croken-end) are cropped with fruit trees; and to such an extent also are Potatoes cultivated that last year one grower (Mr. Vincent) sold six hundred tons of Paterson's Victoria, and in the spring of this year he planted a hundred tons of the same variety.

It is instructive to note the way in which the land is managed for Potatoes, and how the crops are cultivated. The present summer has been remarkable for the great heat and drought which have prevailed in the southern districts, and to this Swanley has been no exception. Scarcely a shower has fallen since the Potatoes were planted. The pastures were parched and the roads were some inches deep in dust, yet the Potatoes were in the most luxuriant health, and the haulm covered the ground so completely that the rows could not be distinguished. A more conclusive instance of superior cultivation cannot well be imagined than is afforded by the condition of the crops. Their admirable state is attributable to deep cultivation, liberal manurings of the ground, perfect freedom from weeds, and persistent surface-stirring—or "crumbing" as it is called in the locality.

The ground is first deeply dragged by the steam cultivator, and is "worked" over and over again—probably seven or eight times before the Potatoes are planted—to form a good "crumb." It is then formed into ridges 2½ feet apart, the sets being planted in the hollows, and the ridges are then "split" and the Potatoes covered. This is the system which is adopted in the large Potato-growing districts of Lincolnshire and Yorkshire, and the only drawback to it is the "sole" that is left by the pressure of the plough, and which in wet seasons prevents the superfluous water from draining away readily, and in dry summers obstructs the uprising of moisture from the sub-soil. This drawback to a good and sound crop—and it is often a formidable one—is removed in the best-managed Potato fields in Kent by a practice which has proved its value, and which is not generally known. When the Potatoes appear above ground in May—that is, when they can be seen in rows, a cranked implement is brought into requisition, and this, with the aid of three or four horses, is made to work quite underneath the

roots from length to length of the rows. This implement runs beneath the plants, and at a depth of a foot from the surface, producing the "crumb" below as well as above the roots, which is so greatly coveted. After this operation the Potatoes grow with great rapidity, and I was assured by one who has worked amongst Potatoes all his life that the value of the crops which have been thus assisted is considerably greater than others which have not been "under-crumbed." The Potatoes are subsequently earthed with the plough or "scuffer," and are dug with forks by the "tatyers," who take them up at a price per acre as is agreed upon according to the nature of the crops. Stable manure brought in trucks from London, and also street-sweepings known as "tackle," are the stimulants mainly relied on to produce large crops of Potatoes.

Peas are also grown on a large scale in the locality—not small early round-seeded kinds, but entire fields of Ne Plus Ultra. This fine Pea flourishes admirably under field culture and yields productive crops. The Peas are sown in drills about 2½ feet apart. The horse hoe is run between the rows to destroy weeds and to promote "the crumb," and the crops then receive no other attention beyond that of the "podders"—men, women, and children, who arrive in due time to gather the Peas for market.

More important, however, than the crop of Peas are the crops of fruit. Plums, Cherries, Currants, Strawberries, and Raspberries are the kinds which are principally grown. Taking a survey of the district from a commanding eminence it is found to be freely, almost heavily, wooded. The woods and plantations in most districts are composed of forest trees, but here the plantations are plantations of fruit trees. There are a few copses here and there of stunted Oaks and Hazels, but these are gradually being removed, and their sites are being more profitably occupied with fruit trees and Strawberries. In the hedges Damson trees appear to grow spontaneously—in fact, the "hedgerow timber" of the district is composed almost entirely of these trees. After the trees have produced fruit for a number of years they are pollarded, or cut down precisely after the manner in which Willows are often treated, and from the old stumps fresh shoots push freely, and in a few years the trees have new heads and yield larger and finer fruit. This mode of heading-down old fruit trees was last year advocated in these columns by several correspondents, and, as may be remembered, others dissented from the practice as being rude and barbarous; but it must be admitted that hundreds of Damson trees in Kent bear witness to the usefulness of the practice which is adopted of "heading them down."

Large plantations of Currants are also to be seen. There are many acres of bushes heavily laden with fruit, and the bushes are very severely pruned, more so than is usually the case in gardens. Raspberries are also very largely grown under field cultivation, and produce annually many tons of fruit. The ground is deeply dragged and well manured, and the canes are planted in rows about 4 feet apart, the plants in the rows being about 15 inches distant from each other. The soil between the rows is frequently stirred with the horse hoe, and weeds are prevented growing and a loose surface is produced which arrests evaporation. The canes grow very short-jointed and become well matured. They are shortened in winter to a height of about 3 feet, and no support in the way of stakes, &c., is given to the canes, each cane, in fact, being sufficiently stout to support itself. The crops produced by this mode of culture are very large, and the fruit is fine, highly coloured, and well flavoured. A favourite variety appears to be Carter's Prolific.

The Strawberries yet remain to be noticed. Hundreds of acres of land are devoted to Strawberry cultivation, and hundreds of tons of fruit are produced annually. The rows of plants are about 2 feet apart, the plants being about 18 inches distant in the rows. The rows are as straight, even if they are a quarter of a mile in length, as are the rows in a well-kept garden, and the plants are perfectly healthy and produce large crops of superior fruit. Each plantation occupies the land for about five years, producing four crops of fruit, and is then destroyed. In the summer, after the fruit is gathered, the runners are trimmed off and also most of the old foliage. The trimming of the plants was being proceeded with in August, when not more than half a dozen leaves were left in the centre of each stool, the others being all cut away. No doubt reasons might be advanced proving that practice prejudicial to the crop, but the fact remains that the mode of culture here adopted is a profitable mode, and failures are exceedingly uncommon. The fruit attains the largest size,

and those who are competent to judge affirm that the flavour of Strawberries which are grown in open fields is much superior to that of fruit which is produced in enclosed gardens. The soil between the rows is kept quite loose with a view of preserving the moisture in the soil; and although there had been scarcely any rain for months, and much of the soil was composed of sand and gravel—soil which one would consider to be totally unfitted for Strawberry cultivation—yet the plants were fresh and vigorous to a much greater degree than is usually seen in gardens—in fact, it is little short of marvellous to see the luxuriance of the plants in a soil apparently so light and poor. In some fields the surface is quite covered with gravel, and when moved little beyond pure sand can be seen; but below the loose surface the soil is moist, and it is this moisture, with the full sweep of wind, which probably keeps in check red spider, to which the remarkable condition of the plants must be attributed. The site of the Strawberry fields is elevated, and the crops are generally better on the hills than in the valleys. The finest pieces of all are on ground from which the copses have been cleared. As the scrubby profitless “wood” is cleared off, Strawberries are planted without any manure, and they flourish in a manner which is quite astonishing. Sir J. Paxton and Eleanor are the favourite sorts.

A visit to this fruitful district suggests how land which may have for many years been almost unremunerative may be turned to profitable account by placing it under fruit cultivation. Strawberries are considered to be the most lucrative crop that can be grown in this district, and their culture has contributed in no small degree to make the fortunes of those who have entered on their cultivation in a spirited and intelligent manner. It is instructive to note the extensive and successful manner in which fruit is cultivated around Swanley, and especially is the value of deeply working the soil and constantly moving its surface most strikingly manifested by the healthy appearance of the crops during a season that has been remarkable for extreme heat and drought.—J.

### NOTES OF A SCOTTISH TOUR.—No. 3.

#### CASTLE KENNEDY.

BEFORE entering into any details of this most interesting place it may be well, as I have said something of the situation of the place, to add a few words as to its climate. It seems to be one peculiarly adapted for the classes of plants which have been used in laying out the grounds; for although lying so far north it is far more mild than many of the southern parts of England—in fact approximating more to that of Devonshire and Cornwall. This is to be attributed, I suppose, in great part to the influence of the Gulf Stream, which divides off the western coast of Ireland, one portion of the current running northwards. Hence the mildness of the coast, snow seldom remaining long on the ground, severe frosts being rare, and moisture abundant; and hence the pinetum at Castle Kennedy passed unscathed through that terrible Christmas eve of 1860, which laid low so many hopes of the landscape gardener in less favoured districts, and this must be borne in mind by any readers of these notes. They may say the statements are entirely opposed to their own experience. It may be so, but then the position and climate of Castle Kennedy are peculiar, and have enabled the noble proprietor and his excellent gardener to achieve results which are impossible in many places. As an instance of this let me note the remarkable manner in which the Sikkim Rhododendrons flourish. They are planted in all directions, flourish as well as the more common kinds, and equally by the beauty of their foliage and inflorescence add wondrously to the effect; and it would surprise many people to see varieties such as *Thomsonii*, *campanulatum*, *campylocarpum*, *barbatum*, *nobilis*, *niveum*, and *lanceolatum*, which we have been accustomed to associate with greenhouse culture, flourishing vigorously in the open air; also one the name of which Mr. Fowler has been unable to ascertain. It grows as rapidly as *R. ponticum*; has long pointed leaves of a mahogany colour on the under side, the upper side dark green; the young wood of a dull red colour. The flowers are white, with dark spots inside, and black anthers. Mr. Fowler is so impressed with the extreme beauty and usefulness of these noble plants, that he is gradually extending them all over the place, and they will soon be quite a feature of themselves. Of the hybrid Rhododendrons there are immense quantities growing on banks and in every available place. Driving along by the loch one sees whole banks of them on the other side, mixed as I have

said with Fuchsias, and these latter were all ablaze with their brilliant scarlet flowers. The species used is *F. discolor*, introduced from Port Famine in 1830, and believed to be the parent of one more generally used and known as *F. Riccartonii*; it is even hardier and earlier than that, and attains here quite a grand size. It is not uncommon to see them 12 and 14 feet high and as many feet through; and as they are freely planted amongst the Rhododendrons and do not come into flower until the Rhododendrons have gone out completely, give a great brightness to what would otherwise be a dense mass of foliage alone.

It is impossible for me to give any adequate idea of the extreme beauty of the planting of the pinetum and ground adjoining. It is not—as one has seen pinetums in other places, where single specimens stand out from all other surroundings—to be admired alone. Here they are in groups and avenues intermingled with other trees. Here, for instance, is an *Araucaria* avenue, in which the trees are in the most flourishing condition—no scorched and naked stems, but all in the rudest health; then we come on a Box avenue, of which the same may be said; then there is a scarlet Thorn avenue. Here again are groups of Irish Yews, and close by an avenue of the Golden Queen Holly. Then again we come on an avenue of *Cupressus macrocarpa* with trees 16 to 28 feet high; while whole quarters of *Pinus cephalonica*, *Picea nobilis* and *P. insignis* met the eye in every direction, together with fine single plants of *P. Webbiana*, *Abies Morinda*, a most lovely Conifer from the Himalayas of drooping habit, *A. orientalis*, very fine, *Abies Douglasii*, a king among Conifers in respect of vigour, habit, and dense dark foliage, and a very beautiful variegated form of it raised here and called by Mr. Fowler *Stairii*. I saw this in all stages from the tiniest plants in the nursery ground up to largish trees, and in all stages it was good and the variegation most constant, and I have little doubt that when better known it will be found as useful as *Acer Negundo* variegata in lighting up plantations, with the additional advantage of being evergreen instead of deciduous. Then *Picea lasiocarpa* and *P. Laricio* were to be seen in great numbers, the latter outstripping in growth the native *Firs*. The Japan species, *A. firma*, also does well, so does also *P. muricata*, and in fact every species seems to thrive.

There are some conclusions which Mr. Fowler's experience has led him to, about which there have been in some cases sharp controversies. It has been said amongst other things that home-grown seed is not as good as the foreign. Now Mr. Fowler totally denies this. He showed us in the seed ground large quantities of such kinds as *P. insignis*, *P. Webbiana*, and *P. nobilis*, which had come up in the greatest regularity and gave promise of becoming sturdy and healthy plants. Then, again, it has been questioned whether grafted trees would stand; but here were trees of *P. nobilis*, perhaps the most majestic *Fir* of all, grafted on the Silver *Fir*, twenty years old, and as vigorous as any tree could be. The value of some of these Californian *Firs* may be seen from the fact that they stand the storms better than the Scotch *Fir*, and the storms on this coast are well worthy of the name. In one exposed part of the ground Mr. Fowler was anxious to get *P. insignis* to grow freely, and he planted as shelter for it some Scotch *Firs*; but now in twenty years' time the former has so grown as to be 7 feet in circumference, while the Scotch *Firs* are not half the size: so that both in an ornamental and economical view we may expect to see in course of time these Californian trees entering largely into the planting of some of the more favoured parts of Scotland and Ireland.

The appreciative writer in the “Quarterly Review,” No. 283, page 83, seems to have had more experience of the southern portion of our islands, and in the matter of Conifers refers with justice to the grand results obtained at Dropmore by good old Mr. Frost. He deprecates the use of *Araucarias* for avenue purposes, and in the ordinary sense of an avenue—i.e., an approach to some grand residence, perhaps he is right. The Elm, the Lime, the Beech, and the Spanish Chestnut may be more suitable for such purposes, but I hardly think that he would complain of the avenue of *Araucarias* here. Evergreen trees are unsuitable for such avenues as I allude to, not merely for the reasons he gives, that “they do not possess the charms of deciduous trees, the different guise of the trees in summer and winter, in and out of leaf,” but there is an amount of sombreness about them all which would lead one in such a case to imagine you were entering a cemetery rather than a private mansion. In gathering lessons from the experience of such men as Mr. Fowler and such plantations as those which

the noble owner of Castle Kennedy has taken such delight in, one must bear in mind the useful as well as the ornamental; "for in earnest matter-of-fact England a hobby retains its favour and prestige all the more permanently if it combines advantage and utility with no æsthetic and sensuous attractions;" and if it can be shown that many of these more recent introductions are not only valuable as timber trees, but also attain more rapidly the size required for such purposes, a greater stimulus must be given to their more frequent employment; and whether one has to improve a property already planted to their hand, or to plant anew for their heirs rather than for themselves, the sight of such places as the pinetum of Castle Kennedy or that of favoured Dropmore cannot but be suggestive of much that is valuable and practical.

And now coming down to smaller matters, Mr. Fowler, be it remembered, is the raiser of that very pretty novelty in Ageratums, "Countess of Stair," of which Mr. Peach wrote favourably to me. Mr. Fowler is engaged in trying still further to improve the race, and fully impressed with the requirements of the day, is endeavouring to combine with novelty of colouring dwarfness of habit, freedom of flowering, and vigour of constitution. There were thousands of seedlings planted out, and there is no doubt that from the care and skill evidenced by Mr. Fowler we may expect some tangible results, thus showing that while he can grasp such subjects as landscape gardening in its full extent, he can yet find pleasure in the improvement of so humble a matter as the Ageratum.

I have said but little of the parterre adjoining the Castle (shown in the engraving in the Journal of the 10th inst.), because, although planted with great taste, there was nothing in it but what may be seen in every large place, but the planting is so unique that it drives other matters in the background. How one could have lingered on the American valley, rejoicing in the foliage and the few Kalmias yet in bloom, and picturing to one's mind what it must have been when Azaleas and Rhododendrons were in their full blaze of beauty; or marked in the pinetum the various shades of green presented by the different species of Conifers, and thought what a picture of beauty another generation will find in these interesting grounds! But I must forbear, and have only to express my thanks to the kind friend who planned this day's excursion, and to Mr. Fowler for the courtesy and hospitality with which he received the "Sassenach."—D., Deal.

#### OTHER FEATHERED HELPS IN GARDENS.

I SAY other, because there are need of other than peewits, inasmuch as their use is limited to walled gardens. What, then, are to be the resources as to feathered helps in unwall'd gardens? This has been a trying year for gardeners in respect to birds. The season has been so hot, and that not a damp but a dry heat—not the heat following rain, but day after day and week after week, the earth baking harder and harder, and dampness utterly ceasing in grass and ditch; so that the birds, the blackbirds and thrushes and other worm and fruit eaters, have been driven to the gardens for fruit alone, as worms have failed. In gardens near to woods the inroad of birds has been unusually great; and even those who are as a rule tender-hearted and bird-lovers, have had their patience sorely tried on seeing, not one or two, but dozens of birds fly out of the fruit trees. Where fruit has been protected by nets, and especially nets fastened on rails as mentioned by J. Muir in his excellent article at page 66, July 27th, gardeners have felt safe and comfortable, but it has been woe to the unprotected. Many have shot at the birds and shot some of them. But the gun is an injurer to tree and bush; and there must always be borne in mind that, cheerful song apart, the blackbird and thrush and the rest assist the gardener during many months, while during a few weeks only they are pilferers. I sometimes fancy that gardeners and others who shoot ruthlessly can hardly be aware of the friends birds are at other times to them. But upon this part of the subject I will not say more, hoping fully to enter upon it in some future papers to be entitled "Our Duty to our Four-footed and Feathered Neighbours."

To return to the state of things this season. Never before have I seen the cuckoos feeding in the garden and always on the same food—viz., the caterpillars on the Cabbages. Sparrows also are great devourers of these. But—and I keep for last mention another feathered help in a garden, and that is the bantam. I happen to have a man who has worked in my garden for the last dozen years, and who, unlike his master, has a perfect hatred of animal and bird, which hatred he with

the privilege of an old servant does not keep to himself. It is always "that dog," with a marked and telling emphasis of dislike upon the word "that;" or it is "They Pigeons" (George's grammar is not good) "have been messing the soft water again and spilling of it." I bear all calmly, for I like strong individuality in character—it amuses me. What, however, was my surprise when the other day George delivered himself oracularly in the following words, "We must have they bantams back again, sir." "Why, George?" "Why, because the garden has got so full of slugs they eat up everything, and when the bantams was here there never was a slug to be seen." "Oh, George, then you have come at last to my way of thinking, have you?" "Well, yes, sir; but the bantams must only be few, and let out during part of the year only an hour before their bedtime: then they do great work and pick up the slugs." There is truth in this, for many bantams would do observable harm by scratching, but with few the good entirely overbalances the little damage done by the busy feet.

A cat is often very useful in a garden, and I have known one regularly chained on a Strawberry bed for the protection of the fruit. Puss did not in the least object to being there, and had her box to go into in case of rain.—WILTSHIRE RECTOR.

#### ROYAL HORTICULTURAL SOCIETY.

As a country horticulturist I regard the position of the old Society more hopefully than I have done for some time past. In that I may be more sanguine than many. I have read the reports of the recent meetings, the general tone of which appears to have been very reassuring. As "heated arguments" and general recriminations are most damaging to any institution, so, on the other hand, sober deliberations have a powerfully beneficial effect. The Society has been racked by conflicting interests, and weakened by passionate advocacy of the policy in which either party was interested. It has been composed of elements that would not blend, and time and money have been wasted in seeking for that which is unattainable. The present Council have recognised this, and they appear to be convinced that the claims of horticulture on the Society which they represent can only be met by the divorcement of the Society from South Kensington. In that they appear to have almost the unanimous concurrence of horticulturists. In a word the Council are trusted, and their policy is generally confirmed as the right policy by all who desire to see horticulture flourish.

Horticulture cannot flourish without a strong, firmly established, and authoritative head. That head is, or should be, the Royal Horticultural Society. At present it is weak, as many believe by its unfortunate alliance, and the sooner a separation can be effected the better will it be for the Society, and the better also in all probability for the district which is known as its head quarters. There may be, and doubtless are, difficulties in the way of a separation from South Kensington being effected, but surely we may hope that no unnecessary impediments will be placed in the way by the Royal Commissioners, and no conditions will be imposed which cannot be borne by the Society. It should be remembered that the connection with South Kensington was effected primarily for the advancement of horticulture, and had the illustrious Prince who commended and supported the amalgamation been happily preserved to the nation, in all probability the union would have been a happy and a prosperous one. Under his patronage and guidance the Royal Horticultural Society would have been made to flourish, simply because that was the primary object of the amalgamation.

The great end in view was not the establishment of a fashionable garden as such—an enclosure for the gratification of a locality—but for the well-being of the horticulture of a nation. That was the end, aim, and object of the agreements entered into with the Royal Commissioners, and the objects are the same now so far as the representatives of horticulture are concerned, but they remain unaccomplished. The policy of the past has failed, the object sought is not achieved, and further efforts are necessary to promote the success of that which was the principal aim of those by whom the present constitutional alliance was projected. The object being still unaccomplished, it behoves all concerned to seek some other way of accomplishing it. The horticulturists as a body have representatives in whom they can trust, and these representatives, as I and many others understand the matter, have not and cannot anticipate the antagonism of the Royal Commissioners, but have a substantial and legitimate claim on their co-operation and assist-

ance. As it appears to me, the Royal Commissioners have in trust the welfare and keeping of the Royal Horticultural Society, and they have endeavoured to carry out that trust, but from (it may be, and probably is) no fault of their own have failed to guide (in conjunction with horticulturists), the Society to a prosperous position. Now when the horticulturists in a united body conclude that the Royal Horticultural Society will be benefited by a separation from their responsibility at South Kensington, it seems only just and equitable that they should have the aid of the Royal Commissioners in carrying out what was the fundamental object of the union of Chiswick with South Kensington. Doubtless it was considered that the Society would have flourished, and the gardens at South Kensington would have been perfected for the promotion of horticulture generally, and for the enjoyment of the dwellers in the "Court suburb" particularly; but when it is found that this double function is not attainable, the question is arrived at, Is the welfare of the horticulture of the nation to be sacrificed for the pleasure of the community of a district? Surely there can only be one reply to that question.

For some time past the dwellers in the country have felt that they did not possess a Society worthy of their support, seeing that the funds subscribed for the advancement of horticulture were in a great measure devoted to the keeping of the gardens of South Kensington. Those gardens are doubtless an attractive feature of the district, but beyond affording convenience for meetings and shows they have not, and it appears to me cannot, benefit horticulture or strengthen the Society. Since the late meetings and the financial statements which have been submitted, it is more than ever certain that country horticulturists will not sink their subscriptions in South Kensington.

Had the Council of the Royal Horticultural Society only the cost of the gardens of Chiswick to provide for, and possessed rooms in London for the committee meetings (which are most important), their shows could be made moveable, having them in different parts of London, and occasionally in the country (a guarantee fund being duly provided); then would the Society be regarded as a real Royal Horticultural Society, and funds would be forthcoming for the promotion of the art in which so many are interested. The suggestions on this point which have been made by Mr. G. F. Wilson are highly worthy of notice, for it is not by the patronage of a select few that the Society can be made prosperous, but by the great body of horticulturists casting their mites together into a common fund for a common purpose will adequate support be provided. These I know are the views of more than one—HOPEFUL COUNTRYMAN.

### COTTAGE GARDENING.

THE annual Show of the Hawarden Amateur Horticultural Society was held on the 15th at Hawarden, and the prizes were distributed in the evening by Mrs. Gladstone.

In responding to the vote of thanks to Mrs. Gladstone for presenting the prizes the ex-Premier said—The trouble is that the circle of topics opened up by a flower show is not a very large one, but at the same time it is one which anybody may be very well contented to treat. There is not a better nor a more wholesome and salubrious village institution in the whole round that can be named than a flower show. In the first place, it is one of those independent institutions which teach the people to exert themselves, and you may depend upon it that man is not a passive and mechanical being. You don't train a man as a plant; he is a moral agent, and if any good is to be done to him or to any woman or child—and I am delighted to see how many young boys and girls have come forward to obtain honourable marks of recognition on this occasion—if any effectual good is to be done for them, it must be done by teaching and encouraging them and helping them to help themselves. As to the people who pretend to take your own concerns out of your own hands and to do everything for you—I won't say they are impostors—I won't even say they are quacks, but I do say they are mistaken people. The only sound healthy description of countenancing and assisting these institutions is that which teaches independence and self-exertion. There is no better kind of exertion than this. It is good for your health, good for your independence, because, though a garden is not a very large thing in the life of a cottager, it is a very considerable element of independence, as well as of comfort, pleasure, and satisfaction, when well managed and of proper size. It makes a sensible addition to his means of living, and for my own part I sometimes hope you, many of you, may live to see the day when there will be no such thing in this country as a cottage without a garden. I rejoice to think that gardens are increasing. We have said before, and I may say now, on my son's part as well as on my

own, that it is our desire to see them increase here. It is not always a very easy thing to make new divisions of land, because, unfortunately, when a bit of land is given to one it very often is taken from another. Land is not a thing that can be manufactured. If we could manufacture it we would make larger gardens, and have gardens for everybody; but as opportunity offers I am glad to think there is every disposition to make them universal. Your independence, your health and comfort, will be thus promoted, as well as neighbourly assistance, good fellowship, and pleasant meetings of this kind, where we are all met in good humour. We come to know one another better, and I hope we come not to like one another worse.

But let me tell you one word more, something more grave than serious, but I hope not sorrowful. When you cultivate the plant that grows from the ground you cannot help thinking a little who He is that makes that plant to grow. When I say you should help yourselves—and I would encourage every man in every rank of life to rely upon self-help more than on assistance to be got from his neighbours—there is One who helps us all, and without whose help every effort of ours is vain; and there is nothing that should tend more, and nothing that does in the well-constituted mind tend more, to make us see the beneficence of God Almighty than to observe the beauty as well as the usefulness of those flowers, those plants, and those fruits which He causes the earth to bring forth for our comfort and advantage.

Now, as I have said before, it is unnecessary and hardly a possible advantage to detain you any longer on an occasion of this kind, but I am very confident that these few words I have spoken are true words, and I believe they will find an echo in your minds, for I must say that the best test of reception of such sentiments is in the zeal and diligence with which the people of this parish have supported this institution and have come forward to claim these prizes. It is to my wife, to me, and to all of us a matter of the liveliest, and I may say intense, satisfaction to see how this institution, which we owe in a great measure to the energy and judgment of Mr. Spencer, has taken root, and is itself, I may say, one of the fairest and most flourishing plants of all those that have sprung up out of the ground. I hope that it will continue to flourish. It is still young. Let it grow stronger and stronger every year. Let us have more and more of the parishioners of this large and growing parish coming forward and competing for these prizes. No enemy will grow out of it—everybody will rejoice in his neighbour's success almost as much as he would in his own. You will all be better for the zeal and energy with which you give yourselves to these useful and healthy pursuits and the support of this beneficent institution.

### NEW BOOK.

*Botanical Reminiscences in British Guiana.* By RICHARD SCHOMBURGK, Dr. Phil. Adelaide.

THIS is a very amusing record of a journey in British Guiana. It contains details of the manners of the people, but we shall confine our extracts to some from the pages relative to the botanical productions.

"Having passed in the course of the day several small tributaries of the Barima, its bed became narrower and more winding, so much that our progress was more slowly. The banks increased in height, and the vegetation became more luxuriant until, with the appearance of that gigantic tree of the Mora excelsa, *Benth.*, which may be called the Oak of the tropics, it reached its culmination. There is none of the European forest trees which could be paralleled with it as a representative. Our large Oaks would only seem dwarfs if standing near one of these giants, the stem of which is overshadowed by the most beautiful dark green foliage. The Indians give this noble tree the name of the 'Chief of the Forests,' and this is the most appropriate name which could have been chosen.

"We were often deceived by these giant trees when we suddenly rounded one of the bends of the river, imagining we saw before us in the distance a number of wooded hills, which, when nearer, changed into single groups of Mora trees, towering high above the surrounding vegetation.

"No idea can be formed of a Mora forest; it is so thick that the sight of heaven is denied to those who enter it. Everything is drowned in a mass of shadows; the eye can only behold a labyrinth of trees of gigantic proportions which astonish and overawe him, garnished with a dome of foliage that darkens the atmosphere, and renders it intolerably heavy and gloomy. Lanes of immense thickness entwine with giant arm these trunks, and ramp to the highest branches, where they crown these giants; then again grow down from this giddy height on to the smaller trees, the branches of which they entwine, and so fetter one tree to the other, with a network, and hold in their strong arms those giants standing close on the banks of the rivers, whose secure position is often undermined by the rapid streams, thus preventing their sudden fall; but should such a

giant succumb, by his fall he will carry all the trees entwined by the same lianes with him to destruction.

"The importance of the Mora for the marine, which my late brother had already pointed out in his first travels, has been confirmed since. On the upper Barima this valuable tree is found in such numbers, and of such immense size, that the trees growing near the banks of the river alone would be sufficient to supply a whole fleet with material. The wood is so close and cross-grained that it is difficult to split it; it is considered by the most competent judges to be superior to Oak, as it is not subject to the dry rot.

"With the appearance of these giants the vegetation near the banks assumed a new character—trees, flowers, fruits, not before seen surrounded me. Amongst these new forms were magnificent flowers of the *Brownea racemosa*, Jacq. I fear no artist is born yet who could produce on paper what Nature has lavished on this dazzling favourite of hers. The elegant form of the pretty tree, by the brilliancy of its foliage, the abundance of large, indescribable, tenderly formed flowers glowing with such dazzling colour that the eye can scarcely bear their sparkling fire; every part combines to captivate admiration—even when the flowers have disappeared the large red legumes offer a pretty picture.

"Although the *Brownea* belongs to quite a different order of plants, and its flowers differ from those of the Rose, I cannot find a more appropriate name for it than "The Rose of the Tropics." The large wax-like white flower of the *Gustavia fastuosa*, Willd. and *Clusias*, increased the preponderating charm. The banks bordered with the 60 to 80 feet high wall-like vegetation, which could be compared to a gigantic clipped hedge, over which hung down in festoons the blue flowers of *Petrea volubilis*, Jacq., and *Schomburgkii*, Schau., also the beautiful red flowers of the *Cacotia coccinea*, Aubl. Nature had even coveted the branches of the gigantic trees, on which numberless Orchids, Tillandsias, Ferns, and Aroids luxuriated, from which the last mentioned suspended to the ground their rope-like roots, resembling the cordage of a ship.

"The *Vanilla*, *V. planifolia*, Andr., and *bicolor*, Lindl., already seen in the lower part of the river, appeared here more frequently, and filled the air, especially in the morning and evening hours, with the aromatic fragrance of its flowers. The plant climbs in a straight line up the trunks of the trees, fastened to the stem by its air roots, their handsome leaves spread symmetrically. Thus it grows from branch to branch, again it descends and strikes roots in the ground, and ascends again. Although the monkeys consider the long, fleshy capsules a great delicacy, we found a large number of the fruits."

"At a small distance from the mouth of the river Pirara, near the bank of the Pirara, we found a gigantic Maran-tree, *Copaifera Jacquinii*, Desf., which showed on its large trunk by old and fresh marks how often the balsam of the tree had been gathered, the entire absence of underwood proving that this spot had been used as a camping place, and it served us for the same purpose.

"To collect the balsam of the *Copaifera* the Indians make a half round excavation in the lower part of the trunk, which extends to the heart of the tree. In certain months, especially in February and March, the resinous juice flows in large quantity and fills the excavation, which from time to time is emptied. We found the hollows full of the balsam, and great numbers of wasps and bees collected around it, which no doubt use the balsam as a cement for their nests. Except for wounds and for the purpose of anointing their body and hair the Indians do not use it for any other purpose. They collect it because it forms an article of barter very much sought for by the Brazilians, and is collected without much trouble."

"On the banks of some rivulets which we crossed in the afternoon appeared again a shrubby vegetation. The pleasure was heightened when these shrubs were seen covered with flowers which I had not met with before; they belonged to the orders of *Proteaceae* and *Ternstroemiaceae*, and were the first representatives of the very interesting genera *Rhopala* and *Ternstroemia*. The whole air was perfumed with the Vanilla-like fragrance of the *Rhopala complicata*, Humb. and Bonpl. This interesting genus appears at an elevation of 1200 to 1500 feet above the level of the sea, although I found the *Rhopala nitida*, Rudge, in the neighbourhood of Pirara. The *Ternstroemia* proved to be a new species, *T. rubicunda*, Klotzsch. Small trees of a *Humiraceae* and shrubs of the peculiar odoriferous *Antonia pilosa*, Hook., changed with the above-named plants, and formed an interesting border along the banks of the rivulet. An oasis through which it was flowing invited us to fix our camp near it. I detected some new forms of plants, to which belonged the *Hyptis membranacea*, Benth., with its tender light blue lip-shaped flowers and green calyx, which, according as the rays of the sun fell on it, changed from green to white and to pink. The leaves of this magnificent tree, which reaches a height of from 30 to 40 feet, emitted a strong aromatic smell. Its wood is very hard. This is undoubtedly the only tree-like *Labiatae* indigenous in British Guiana. Mr. Gardener, the well-known

traveller and botanist, found this species also in Brazil in the diamond district, Minas Geraes, near Cidado do Serro, as one of the most common trees; its distribution, therefore, seems to be over a large area in South America. A new *Swartzia* and *Rhopala*, *S. capparoides*, Klotzsch, and *R. suaveolens*, Klotzsch, I found also here."

"Enraptured with what we had seen through the beautiful magic garden of flowers, we were especially interested by seeing large trees of the *Ladenbergia*. At the Humirida Mountains, in an altitude of 3690 feet above the level of the sea, we found them only as shrubs, here we met them as trees.

"No other order of plants could probably show a more abundant literature than the *Cinchonae*, and yet the knowledge of the geographical distribution in South America of this valuable tree is very limited, as every new traveller has added other discoveries.

"Many are the causes ascribed to the discovery of its wonderful effects of alleviating the sufferings of humanity. No doubt assertion made in proof of it belongs to the region of legends, by which generally an important discovery is accompanied. According to Geoffroy, an Indian afflicted with fever drank out of a pool into which had fallen trees of the fever bark, and by drinking had been cured of his illness. According to Condamine (although he himself doubts the truth of it) the American tigers, the pumas, were the first that drew the attention of men to it, because these animals, which are supposed to be attacked by fever, cured themselves by gnawing the bark of the *Cinchona* trees. Some of the oldest authors assert that the Indians were acquainted with the qualities of the bark before the arrival of the Spaniards; while others again maintain that they did not know its valuable quality.

"It has been proved by later travellers, especially through Alexander Humboldt, that the discovery of the bark as a medicine belongs to the Europeans, and not to the natives of South America. Just as unacquainted as the great traveller found the Indians with the qualities of the bark did my brother in his first travels, and even now we found this the case with the *Arekunas*, who lived in the *Cinchona* region. We gave the Indians, when we found them suffering from fever, quinine, and gained lasting gratitude for it, while a few steps from their sick bed the source of the remedy was growing in luxuriant abundance."

## THE HOLLYHOCK.

THE Hollyhock takes such a high position amongst autumn-flowering plants that it is scarcely necessary to speak in its praise. I can add without fear of contradiction that no other plant grown combines the qualities suitable for shrubbery and border decoration to the same extent as the Hollyhock. It is easily cultivated, requiring only a little protection through the winter—a few coal ashes shaken over the crowns and removed in early spring being all that is required.

It is generally propagated either by seed (and seedlings make the best plants), or by cuttings—single eyes taken off in August and inserted in light soil in pans well drained and plunged in a frame in leaves or tan, so as to have the assistance of a little bottom heat. This is a quick method of working-up a stock. Give air as required when the eyes have made a little growth, and when they are sufficiently rooted pot the young plants singly in 3-inch pots, and replace them in a close frame for a few weeks, and when the pots become full of roots give the plants a shift into 6-inch pots, using one-half of rich loam, one-fourth of well-decayed manure, and one part of leaf soil, with a good admixture of silver sand, all well mixed together. At this stage the plants may be placed in a cool pit or frame for protecting them through the winter, admitting plenty of air on all favourable opportunities. They will be ready for the open ground in spring.

To increase by seed, the seed should be gathered early in the autumn from the most double blooms of the finest shape and colour. Sow it in pans, and give the seedlings the same treatment throughout as plants from single eyes. I have practised this mode of culture and have found it most satisfactory.—J. HOBBS, *The Fernery, Kent.*

## HYACINTHUS CANDICANS.

Now that the tide of popular favour is again flowing, we are glad to say, in the direction of the mixed border and the cultivation of choice hardy flowering plants, a new and really good plant in that way cannot fail of a welcome and due appreciation. Such unquestionably is the beautiful *Hyacinthus candicans*, incidentally alluded to last week as being in flower in the open border at Glasnevin, and of which it is now proposed to speak more specifically. In the first instance, we must ask our readers to disassociate it altogether, so far as regards

its aspect, from the Dutch or other ordinary border Hyacinths. In fact, the consanguinity is, as regards aspect and appearance, scarcely to be suspected. This will be understood when the reader is told that Hyacinthus candicans has Crinum-like glaucous leaves from 2 to 2½ feet long, and broad as those of Crinum capense, that the stout flower scape rises straight as a gun barrel to the height of 3½ to 4 feet, and the topmost foot or 18 inches decked with large pendulous bells of exquisite form and purest white, except a slight tinge of green towards the base. The flowering period is very prolonged, indeed some six weeks or more, the flowers being produced in succession as the spike elongates. This aptly termed "colossal Hyacinth" is admirably figured, and, what is more, truthfully depicted, in last year's volume of the "Flore de Serres." It comes to us from Natal, and is perfectly hardy. Moreover, the very moderate figure, between 3s. and 4s., at which fine flowering bulbs are obtainable, places it within the reach of all lovers of fine hardy border plants, and to the notice of all such we strongly recommend it. As a pot plant for house culture it would, we should say, be singularly striking and effective; and further, there does not appear any reason to doubt it being an excellent subject for early forcing or its amenability for the purpose. With regard to the freedom or otherwise with which offsets are produced, and the plant thereby multiplied, our too brief acquaintance with it does not enable us to offer an opinion.—(*Irish Farmers' Gazette*)

#### SIR J. PAXTON STRAWBERRY.

As several persons have spoken against this Strawberry I should like to state a little on the other side of the question. I think it undoubtedly one of the best Strawberries in cultivation for a dry soil. The fruit this year has been very fine, [the quality first-rate, and the crop very good.

I have seen it classed in some catalogues as an early, in some a midseason, and in others a late variety, but it is properly classed as a midseason variety. A few of the berries began to colour this year as early as Keens' Seedling, but the fruit does not ripen off so quickly—in fact it is a slow ripener, and that is a very desirable quality if you have a good net over the beds; for if you do not happen to want the fruit you can leave it. I left one bed for more than a week after the fruit was ripe, and when gathered it was of fine quality; but it must be remembered the weather was dry.

Last season was the opposite of this, but Sir J. Paxton stood the continual washings of rain as well as any other variety.—*AMATEUR, Cirencester.*

#### FRUIT-GROWERS' ASSOCIATION OF ONTARIO.

The following are extracts from the President's address, and from some of the members' notes:—

We question if ever fruit-growers had to contend with more malign influences than those which have prevailed during the past winter. The season was exceptionally severe, and some noticeable and remarkable effects resulted to almost all vegetation from its severity. The Apple, Pear, Plum, Cherry, and Grape suffered greatly. There are few horticulturists but have to lament the destructive inroads made on their orchards. Scarcely an orchard escaped the biting blast. It matters little the aspect—trees on southern slopes suffered as much as those on northern exposures. Nor were other varieties of trees exempt. The hardy Oak, the luxuriant Maple, the stately Pine, and the lowly shrub alike suffered, and this not in one district, but almost everywhere. Confessedly hardy varieties were more injured than certain others that were previously known for their tenderness. Philadelphia Raspberry was cut down, while in its neighbourhood the hornet stood the winter pretty well. Grape Vines in southern exposures were scathed, while the same varieties in northern aspects passed through the ordeal scatheless. The strangest and most paradoxical results have been noted. Important lessons follow. At Drummondville we learn that the mulching of the tender varieties of the Peach had preserved them. In fact, the severity of last winter has abundantly taught the beneficial results of mulching. Trees well mulched suffered comparatively little—left exposed they scarcely survived. The practice of mulching must soon become general, and this both in winter and in summer. In winter it is needed to protect against the withering cold, in summer as a shelter against the intense heat. My own experience is strikingly illustrative of the benefits of mulching. For years I mulched either with manure

or turf—for the last two years I have applied fertilisers in both cases on the surface. During the past summer and spring branch after branch of my beautiful and fruitful Pear trees have gone. My occupation has largely been to trim off great quantities of blighted limbs, and the evil I fear is not over yet. I propose to return to my old mode of culture, and mulch both in winter and in summer.

In a part of my front green I have purposely kept the ground free of weeds and grass. Every tree on this particular plot has suffered; my Pear trees have actually died out, and my Apples have greatly suffered. I intend in the spring to sow grass seed or Clover to protect the roots of my trees. After all, there is something in this grass theory and practice. I am satisfied that a good crop of weeds has something to do with a good growth of wood, and with the fertility of fruit-bearing trees. Some manure which I once employed as a top-dressing was full of groundsel seed. A luxuriant crop of what was esteemed a noxious weed was the consequence. Not a single bough, however, blighted, notwithstanding the luxuriance. Thinning it proper and right, I got rid of the groundsel, and have for these two years kept my ground clean but undug. This tidiness on my part has been further carried out by an orderly and painstaking workman, who raked into heaps every bit of bark, bone, pruning, old shoes, rags, &c., which offered a certain kind of mulch, and thereby left the ground bare and clean. The result, come from what cause it may, has satisfied me that trees like a little roughness. Forests mulch themselves. Mr. Saunders of London can tell a somewhat similar tale, or rather his grounds do if he won't. Having recently visited his fruit farm, I can testify that even a grass mulch is unmistakably beneficial, and highly subverses the interest of the horticulturist. Among trees on cultivated land there is at London a very high percentage of deaths; in the same varieties grown under grass in the same, nay, almost the immediate position, the percentage of deaths is not a tithe. This speaks volumes for unwehing; indeed, mulching is a great necessity. At Ottawa in June last I noticed in Mr. Bucke's garden that the canes of his Raspberries were scarcely touched. In attempting to account for this I found that he had been attending to first principles, and that his Vines were and had been growing under a course of very heavy manuring.

We have noticed that good hybrids are less liable to be attacked with blight than imported varieties. Crosses are yet to be made which will combine hardihood with quality. Our hybridists are on the track. Skill and delicate manipulation will yet accomplish their wonders. We are only on the threshold of great discoveries in hybridisation. Facts are becoming more and more patent which show the wonderful influence of the stock upon the scion. Stocks ought to be selected with the greatest care. That any stock will suffice is an idea that happily is becoming exploded among fruit-growers. Were testimony to be desired as to the effect the stock has upon the scion, it is not wanted to those who have noted the disastrous results of the past winter. Take for example the Cherry. Cherries worked on the Mazzard stock have in most cases been killed outright, while those on the Mahaleb, standing in close juxtaposition, have in many instances escaped. The Mazzard cannot be compared to the Mahaleb as a stock. Were growers to order trees on the Mahaleb stock they would not suffer so severely as they have done from the severity of winter. Mr. Saunders' Cherries on his farm in the neighbourhood of London have almost all suffered that were on the Mazzard; those on the Mahaleb, while showing symptoms of having suffered, are comparatively uninjured contrasted with those on the Mazzard. What is true of the Cherry on Mahaleb and Mazzard stock is equally true of Pear stocks. Some varieties of stock are naturally dwarfish of themselves—in their own nature—and some are rampant growers. These differences are to be found in the smallest quantities of Pear stock. I have a Lawrence on the Pear stock, which has the diameter of the stock double that of the scion. The consequence both of the growth of the wood and of the fruit is that it far exceeds its neighbours both in wood-growth and in fertility.

The art of hybridising requires some knowledge of botany and a little delicate manipulation. The female is usually chosen for its qualities as a plant, the male for that of the fruit; because it is found the former takes after the mother, the latter after the father. These being selected by the experience of the cultivator, the first process in hybridising is to open the flower just before it would naturally do so of itself, and remove the little cap that covers the pistil with a pair of forceps, then take away the male organs or anthers. So soon

as the flower buds selected are thus prepared they must be enclosed in a paper bag until properly suited for the application of the pollen. This may be from one to two days; but sometimes, if the buds are very far advanced, they may be acted on immediately, and again a few days afterwards, which will increase the chances of success. Care must be taken to keep

easy. The tuber only needs to be planted in a mixture of loam, peat, and sand in the spring and be placed in a genial temperature, when the plant will grow freely, and in due time flower profusely. It is most attractive for conservatory or room decoration, being remarkable for its elegance and in being quite distinct from other plants with which it is likely

Fig. 19.—*Dioscorea retusa*.

the flower as closely covered over as possible, so that they may not be impregnated except by the hand of the operator. The pollen should be collected in a piece of blue paper by holding it under some flowers and jarring the branch several times, when a shower will fall. This should be quickly rolled up and excluded from the light, and may be kept for weeks to be ready to operate with. This is done by taking up some of the pollen collected on a camel-hair pencil and applying it gently to the female organ or pistil. As before stated, this operation should be again repeated in a day or two. The flower should then be covered by a paper bag, and when the fruit has formed this may be removed and one of muslin supplied, which should be kept on until the fruit is ripe, so that nothing can carry it away. The seeds should be sown in the autumn, and the next year plants will be obtained a foot in height. These should be taken up and removed to some secure place where they will not freeze, and be replanted again in the spring. Fruit may be expected on these seedlings in from four to five years' time.

### DIOSCOREA RETUSA.

COLONEL R. TREVOR CLARKE informs us that "this *Dioscorea* was one of many most curious and interesting plants collected by Cooper in South Africa, and presented to the Horticultural Society by Mr. Wilson Saunders. As the plants were not calculated to make ribbon borders or other such delights of the day, they were overlooked by the Fellows; but I tested all or most of them, and keep them still; and a *Cassonia* labelled 'Testudinaria' is now one of the handsomest plants in my conservatory.

"*Dioscorea retusa* is a very striking plant whether trained parasol-fashion in a pot or allowed to climb and ramble as a conservatory ornament, with its Hop-like aspect and pleasant fragrance. It seems to require a warmish, or so-called intermediate, house, to show its full capabilities, although in effect it is hardy, or nearly so."

We may add that this plant was exhibited in splendid condition by Messrs. James Veitch & Sons at the Great International Exhibition at Brussels, and perhaps no plant was more generally admired. As occupying the central position in the rich group of Orchids, &c., its appearance was most striking; its graceful habit and distinct pendulous racemes having a fine contrasting effect with the more highly coloured plants by which it was surrounded. The cultivation of this plant is very

to be associated. After the plant has flowered it may be placed in a sunny place in the open air to mature its tubers, and be started into growth again early in spring.

It is a plant which is likely to become popular, and is well worthy of notice as a distinct and ornamental summer decorative plant.

### DEATH OF MR. PEARSON OF CHILWELL.

HORTICULTURE has sustained a severe loss in the death of Mr. John R. Pearson of Chilwell. The sad event took place on the afternoon of Monday the 14th inst., at his own house

at Chilwell near Nottingham, where he has for some months been suffering from a long wasting illness.

Mr. Pearson was born in the house where he died on the 29th of January, 1819, and was consequently in his fifty-eighth year. Although the three last generations only were nurserymen, the family have been resident in the parish between three and four hundred years, the earliest record of them being in the registry of the parish of Attenborough, in which Chilwell is situated, in 1527. Mr. Pearson's grandfather, born in 1752, was the first of the family who appears to have been a nurseryman. He was a great florist, and had what was considered one of the best collections of Tulips in England at the time. The Polyanthus and the Picotee were also among his favourite flowers, and he raised Pearson's Alexander Polyanthus, said to be the best ever sent out. To him also is attributed the origin of Pearson's Plate Apple and Pearson's Prolific Nut. He was buried in Beeston churchyard, and a stone there commemorates the resting place of "John Pearson, Nurseryman." Though the father of this John Pearson, and great-grandfather of our subject, lived in the same village in a property still belonging to the family, there is no evidence that he was a nurseryman, and we therefore infer that the grandfather was the founder of the Chilwell Nurseries.

There are documents in existence which show that the ancestors of the present family were possessed of lands in Chilwell in the time of Cromwell, and there can be no doubt that some of the Pear trees which still exist in the extensive orchards still belonging to the family are of very great age, for both Mr. Pearson and his father (who was born in 1778), used to say that they had not visibly increased in size during their lives.

It was in the year 1843, two years before his father's death, that Mr. J. R. Pearson succeeded to the nurseries at Chilwell. Even then they were among the most noted of provincial nurseries, but it was mainly through the energies of Mr. J. R. Pearson that they were so greatly developed that at the time of his death they are among the most extensive and important in the country. With him his profession was his delight, though he originally had a preference for the law. The way his father led him on to horticulture was by building him a greenhouse to give him a taste for plants. This had the effect; and while that was the first glass structure ever seen in the grounds, there are now twenty-five of those large handsome structures which have been the theme of many a subject in horticultural literature. Whatever Mr. Pearson did, he did it well and thoroughly, and he brought to bear upon it the powers of a highly educated and intellectual mind, which penetrated the most minute details of the establishment, and not only guided and directed but influenced those around him. Whatever Mr. Pearson said, did, or wrote, had a cast of originality about it, and his way of handling a subject was sure to attract attention by the air of novelty which appeared to surround it. The pages of this Journal have for many years been enriched by his literary communications, which were invariably of the most sensible and practical description. Mr. Pearson rarely dealt in theories, his mind was too observant to allow facts to escape him, and it was upon facts he chiefly relied. All the papers that have appeared in this Journal testify to this; and so striking often were the subjects he discussed or originated, that they invariably attracted attention and set others thinking in a train in which they never thought before.

Of late years Mr. Pearson's attention has been mainly given to the improvement of Grapes and of the class of flowers known as Scarlet Geraniums. On both of these he did not enter as many do at haphazard, but he set about his work systematically and with the intelligence with which he was endowed. In his endeavour to obtain new varieties of Grapes, for instance, he was not content merely to save the seeds of existing varieties and from these to raise seedlings, but he carefully introduced into the commonly cultivated varieties the elements of a new race altogether, and thereby infused into the Vine of the eastern hemisphere the characters of that of the western. By hybridising the Royal Muscadine with pollen of the Strawberry Grape he succeeded in raising that exquisitely flavoured Grape Ferdinand de Lesseps, and that in its turn has served as the parent introducer of new flavours into other seedlings he has raised. Ferdinand de Lesseps was first exhibited in 1870, when it unanimously received a first-class certificate of merit from the Royal Horticultural Society. In the same year he exhibited Chilwell White, which also received a similar award. This was in

almost every respect a white form of the Black Hamburg. In 1871 he raised the large black varieties named Abram Bass, Chilwell Alicante, and Emperor of Morocco, all of which were excellent in flavour, but of which we have not heard much since. In the same year he exhibited a fine, large, white Grape with a Frontignan flavour, which he named Dr. Hogg, and which received a first-class certificate. The parent of this was Duchess of Buccleuch; and while it has the large, tapering, and well-shouldered bunch of its parent, the berries are larger than those of any round Muscat Grape, with a richness of flavour equal to that of Chasselas Musqué. In 1873 Golden Queen was first exhibited and received a first-class certificate. It was raised from Alicante fertilised by Ferdinand de Lesseps, and is a remarkably richly-flavoured, oval-shaped, amber-coloured Grape. In 1874 appeared his crowning triumph in Grape-raising, and this was appropriately named Mrs

Fig. 20.—Mr. J. Royston Pearson.

Pearson. The origin of it is the same as that of Golden Queen, and it at once was awarded a first-class certificate for the large and handsome bunch, and the exquisitely rich flavour of the berries left not a moment of hesitation on the part of the Committee when they made the award.

Mr. Pearson's own account of his work in raising new Grapes is as follows:—

"Some years since, hearing that the native Grapes of North America enjoyed a comparative immunity from the attacks of mildew, I resolved to cross one of them, the 'Strawberry,' with our hothouse varieties. I raised about a hundred seedlings in this manner, using in every case the Strawberry as the female parent. Many of my friends will remember the interest this experiment excited at the time from the extraordinary character of the foliage produced.

"The 'Strawberry' Grape has small woolly leaves, very little cut, indeed nearly heart-shaped; the seedlings were all deeply cut, some of them small, and some of immense size. I remember the Rev. C. P. Peach of Appleton-le-Street, Yorkshire, asking me for a leaf as a curiosity, which was inches bigger in diameter than a page of the *Times*. The fruit of these seedlings varied as much as the foliage, being of all colours, and I may add of every degree of nasty flavour, except one or two which were golden in colour and very sweet. Of these I chose one only to keep, which was exhibited in London, August, 1870, and received a first-class certificate as 'Ferdinand de Lesseps,' and I think richly deserved it, not so much as a new Grape as a new fruit altogether. With me it is a strong grower, a most abundant bearer, and of a beautiful golden colour. The fruit being scented with Strawberry, and tasting like barley sugar flavoured with Pine Apple according to some, and like new honey according to others, is totally unlike any other known Grape.

"Here was at least a great curiosity, a pretty scented fruit, which few with their eyes shut would take to be a Grape. But everyone does not like barley sugar, or new honey either, and then, unfortunately, the berries were little larger than those of the Frontignan, and the bunches scarcely so long, and though 'Ferdinand' found many admirers, I never recommend anyone to plant it who had not seen and tasted it.

"I next tried what the effect of crossing Ferdinand with other Grapes would give, and raised another large batch of seedlings, some also from other crosses, which were all planted together. Some of these were exhibited 6th September, 1871. From them the Committee of the Royal Horticultural Society selected one for a first-class certificate, and as the Chairman, Dr. Hogg, appeared much struck with it, I named it after him. Now I had great doubts about the value of this variety, and told the Doctor so, and also the Committee. I knew it was a seedling from the Duchess of Buccleuch, and never could make up my mind what was its other parent, or if it had been crossed at all. Knowing that all the race of Grapes, comprising Muscat, Muscadine, Chasselas Musqué, and Joslin's St. Alban's, which were the result of a cross between the Muscat of Alexandria and Royal Muscadine, to which the Duchess of Buccleuch belongs, were, though very high flavoured, dreadfully subject to crack, I feared the same might be the case with mine, and never would recommend it to anyone. Besides growing in a north border of a Geranium house, it never was very well ripened, and appeared not to retain its high flavour after it was ripe. With these ideas I let anyone who chose to have it take it at 10s. 6d. a plant, and as may be imagined, made little of it. Now, when it is out and in other hands, as many no doubt have heard, it is proving one of the best Grapes in cultivation. With me it has never cracked a berry, and whilst quite equal in flavour to the Duchess of Buccleuch, it is twice the size, bunch for bunch. While such men as Spencer, Speed, Dr. Hogg, Woodville, Petch, &c., are praising it as one of the best new Grapes—indeed Mr. Petch says, the best new Grape—I have the satisfaction of feeling I gave it away; never mind if I made money by it and everyone abusing it, I should have found that harder to bear than my friends' laughter now.

"Coming now to the 'Golden Queen,' it is a seedling between Ferdinand and Lesseps and Black Alicante. It fruited for the first time in a pot standing on the border of my Fig house. Finding it had made a root through the bottom of the pot, I broke the pot to pieces and hilled-up the ball with fresh soil. No one expects a Vine that has fruited in a pot to do much the following year, but to my surprise this carried thirteen bunches, perfect in every respect.

"The bunch and berry are exactly alike in shape to the Madresfield Court, but in colour is a bright gold. The flavour is that of a Muscat of Alexandria without any of the aroma peculiar to the Muscats, being, in fact, a rich, fleshy, sweet Grape. The foliage shows its hybrid origin, being strong, dark-looking, and feeling to the touch more like that of a Fig than a Vine. The wood is a bright cinnamon in colour, and taking fruit and Vine together, it is perhaps the most beautiful Vine ever seen growing. From the large amount of water used in the Fig house and the little heat employed, mildew attacked most of the Vines in the same house, but the robust foliage of this variety appeared almost mildew-proof. Lastly, only two kinds under these unfavourable circumstances were really ripe in the house, and the Golden Queen was one of them: many have only half ripened their wood, and the thinnest shoots of this are as dark in colour and as hard as the thickest.

"The Committee which awarded it a first-class certificate was the largest I ever saw sit at Kensington, and I am told there was not a single opponent, and on my rejoicing the Committee I was not only congratulated but received a number of orders from some of the best judges at the table.

"I will not give this Vine away as I did 'Dr. Hogg.' If I do not receive from one to two hundred orders I will keep it till I do, having spent hundreds of pounds in raising seedling Vines without any remuneration; and having a really good thing that I can recommend without fear, few will blame me for expecting a little return for trouble taken and money spent. Having anticipated as far as possible every question likely to occur to my friends, let me conclude by saying that I shall receive their orders with pleasure and thanks, and they shall be executed in the order they are received."

In his efforts to improve the race of bedding Geraniums Mr. Pearson had a definite object in view—of imparting to the floriferous Nosegay section the broadness of petal of the ordinary Zonals. How he succeeded is a simple matter of history, and the successive batches of Chilwell Geraniums were always looked to as possessing qualities of a high order. The colours are now so varied, the trusses so fine, and the habits of the plants so good, that they have attained to a foremost place amongst summer decorative plants both for the flower garden and the conservatory. For the past few years the finest beds of Geraniums in the London parks had their

origin at Chilwell, and at the present moment these Geraniums occupy commanding positions in the parks of Hyde and Battersea. The newest varieties sent out during the present year are exceedingly fine, notably Mrs. Lancaster, pink, grand, rich, and massive; Louisa, lovely pink with darker spots; Mary Gregory and Mrs. Pearson, rose; Frederick William and Capt. Holden, plum-coloured; E. Davies, purple crimson; Leopard, salmon; David Thompson, crimson; and Lord Zetland, Havelock, and Wordsworth, scarlets. These are amongst the most striking varieties which have ever been raised, and are worthy of the latest efforts of one of the most successful hybridisers. Mr. Pearson was an active member of the Pelargonium Society, in fact was one of its originators, and continued to the end one of its best supporters. He was also for many years a member of the Fruit Committee of the Royal Horticultural Society.

Mr. Pearson's contributions to horticultural literature extend over a number of years, and some of the most important of them have appeared in the pages of this Journal. He is also the author of several useful treatises. His "Hints on the Construction and Management of Orchard Houses" has gone through four editions, and "Vine Culture Under Glass" has passed through three editions. Both of these are most reliable guides on the subjects upon which they treat.

The Chilwell Nurseries will, as a matter of course, be continued in all their wonted vigour. The same spirit that actuated their predecessors governs the present family, and the business will be conducted under the title of "J. R. Pearson," as before.

## ORNAMENTAL AND USEFUL TREE-PLANTING.

No. 2.

WHATEVER change the use of ironclads—(the drawback to Oak timber in immediate contact with iron is its powerful pyro-ligneous acid, which corrodes the metal and deteriorates the wood. For this cause the Indian teak and the Angelique of Guiana are in request for the backing of armour plates, but for the floating hearts-of-oak which won our naval supremacy Mr. Leslie does not hesitate to set up the British Oak as the standard)—and the demand for Larch to furnish railway sleepers may have wrought in the economic pre-eminence of the Oak in point of dignity, ornament, and ancestral associations, it must still rank as foremost of English trees. "A Larch may buy a horse before an Oak can buy a saddle;" but where is the Larch or Larch grove that can pretend to a credit like that of some of the Oaks in the New Forest, in Arundel Park, in Bagot's Park, at Moccas, Holme Lacy, or a hundred other places; gigantic of girth, weird, gnarled, and massive of limb; and even in age vouchsafing such a prolixity of shade and shelter from their still leafy tops, that we can well believe the stories told of a troop of soldiers bivouacking of old under one such sylvan canopy? In point of duration the Larch is a mere fungus to the Oak, of which Dryden's couplet understates the truth in saying—

"Three centuries he grows; and three he stays,  
Supreme in state; and in three more decays."

The Saley Forest Oak in Northamptonshire could have told if gifted with speech of thrice five, not thrice three centuries; the Winfarthing Oak (Norfolk) was an old one at the Conquest; and there is a fair show of Oaks still in English counties that can sustain a claim to sexcentenary or semi-millenary honours. But where would have been their glory had our remote ancestors regarded the economic return of planting, and had the "dirty siller" been its sole or chief incentive? It is permissible in the planter to bestow half an eye on this, in so far as, in choosing nurses for the Oak which he should plant wherever there is soil congenial, he selects such trees as yield a quick and ready return, and pay—even the longest spared of them—their debt to the axe, or even the Oaks they have nursed attain to even the average honours of maturity. There is, we believe, little doubt of the superiority of the wavy-leaved Oak, with its fruit stalked and its leaves sessile (*Quercus pedunculata*), to the flat-leaved (*Q. sessiliflora*), which has its leaves stalked and its fruit sessile, or close to the branches. Selby considers both to be rather varieties of a single species, while Laslett doubts how the timber can be distinguished without access to the converter. Intermediate varieties are doubtless by no means uncommon; but though the sessiliflora is now determined to have furnished the roofs of Westminster Hall and others of our oldest buildings, till lately supposed to have been Chestnut, the pedunculata is still more esteemed in

the timber market; and so far is the Oak to covet, and this with the less sin, as it is the more prevailing kind. Though the sessiliflora is counted a handsome tree for its upright habit, graceful branches, and larger and brighter leaves, it matters less, inasmuch as only when young is there much perceptible difference between the two species or varieties in size and growth. Given a clay loam for soil and subsoil, with natural or artificial surface drainage, and the English Oak will not lag far behind rival timber trees in quick return or remunerative growth, nor yet cause a pang of hope deferred by delaying the promise of a distinct feature of the landscape. To say nothing of coppice wood, it is calculated that by careful thinning, selection, and replanting, an Oak plantation may be made to pay in suchwise that there shall be no serious locking-up of capital between the sowing and the ninetieth year—in favourable soils a good time for cutting. By that time the Oak will be eminently picturesque; though, as Gilpin notes, it is “through age that it acquires its greatest beauty, which often increases, even into decay, if any proportion exists between the stem and the branches.”

For its merit of indigeneity the British Oak should find place in every English park and lawn meadow. It is a study in bud, blossom, leaf, fruit, and life; in its epiphytes, the Ferns, Fungi, and Mosses, which add to its interest, whether standing or prostrate; and even in the curious spangle on the Oak leaf, of which the clusters puzzle the uninitiated, a phase of insect architecture, a golden-brown egg, which supplies the pheasant with one of its choicest delicacies. But, not to linger on curiosities, we would fain draw the attention of those who rate present pleasure above their debt to posterity, to a feasible compromise in Oak planting. Where ornament is the prime aim, but use and profit still a partial consideration, they might do worse than plant the *Quercus Cerris*, or Turkey Oak, a deciduous tree with a mossy hemispherical cup, and lobed irregularly-toothed leaves of a glossy green above and an almost white beneath. Though deciduous itself it hybridises with the Evergreen Oak, and might pass for an *Ilex* by reason of its leaves, though they die in autumn, clinging to it through the winter. Its rapid growth makes it a straight tall adult when the English Oak is yet a child, but candour bids us add that this maturity is purchased at the cost of the grandeur of ramification to which the latter attains at full growth. Still it is a consideration to get an Oak which in a good dry loam will repay its planter in forty years, either by its park-like aspect standing, or its availability as wainscot of beautiful grain when felled. It was introduced into Britain from the south of Europe in 1735, though indigenous in Asia Minor, and is propagated by the acorns; though its sub-evergreen varieties, the Lucombe and Fulham Oaks, hybrids between it and the Cork tree, can only be increased in their purity by grafting. Both these are alike in breadth of leaf, but the Fulham Oak's habit of growth is round-headed, that of the Lucombe decidedly spiral. The original Fulham Oak is to be seen at Messrs. Osborne's of Fulham, a locale where many introductions and hybrids of the seventeenth century may be studied with profit. A charming variety of the *Q. Cerris* is the *Q. Cerris pendula*, a weeping tree very worthy of culture.\* The Cork tree (*Q. Suber*) is a rarer and less striking tree than its cross-bred progeny. It is an evergreen introduced from Spain, and in a rich dark loam will grow to 40 feet, and exhibit a luxuriance of dark green foliage, contrasting well with its frosted silver bark. This latter is detached from trees of twenty years' growth and upwards “in pieces about a foot square and 1 inch or more thick, and the operation is repeated every eight or ten years, by which time the cork substance is renewed without any detriment to the tree.” Loudon and Grigor quote the king of Cork trees as at Mamhead, Devon; but there is one of fine proportions in the Fulham Nursery. The *Ilex* needs little recommendation, and practised horticulturists still less caution against undue multiplication of it. Its drawback is a certain sombreness; its charm a grandness of diameter, arising from its being clothed from head to foot, when it stands out alone, with a dense mass of leaves and branches. Of later years America has contributed many valuable species of the Oak to our parks and gardens. The kindred

*rubra* and *coccinea* are both presumably hardy, and both notable for a glossy green summer foliage, which turns in autumn to a rich scarlet or purple. The leaves are large and oblong, on long stalks; and fine specimens of *Q. coccinea* are to be seen at Croome in Worcestershire, and at Strathfieldsaye. The speciality of *Quercus alba* is its silvery bark; in fruit and leaf it is a finer sessiliflora. It wants a good soil and a warm situation; with which advantages, in the Grove at Muswell Hill, there is one which, at seventy-two years of age, stands 61 feet high. Selby's doubts of its success in this country arose probably rather from observation of its slowness of growth in exposed places than from any susceptibility to frosts. The *Q. nigra*, or American Black Jack, is as fastidious about soil as its opposite. It takes its name from the blackish-red which characterises its wedge-shaped leaves before the fall. The *Phellos*, or Willow Oak, deserves planting for its elegant habit of spray, as well as for its hardihood; and the *Q. prinus* is attractive for its Chestnut-shaped leaf, and is quite hardy in the neighbourhood of London.

From a contemplation of both, with an eye to the picturesque, Gilpin ranks the Ash next to the Oak—the “Venus of the Wood” next after the Hercules. Yet it is not a tree for every situation, and, though strikingly effective at the corner of a wood or on the slope of a ruined abbey, should be sparingly planted near a gentleman's residence, and this because, coming latest of all trees into leaf, it is almost the first to shed its foliage. So much is this the case, that the expansion of the Ash leaf is reckoned as safe an indicator of the season of bedding-out as the fall of it is a hint to remind such fine folk to shelter. As a natural result of such a long term of leaflessness too many Ash about a place impart to it a cold and barren appearance. But even the common Ash, in maturity and in age, with a congenial soil and situation (a hill bottom, or a well-drained riverside slope, and a deep loam) is a tree to admire and reverence. One at Woburn Park measures more than 90 feet in height and 20 in girth, and contains 872 feet of timber. Others at Longleat show 50 feet of clear stem, and measure 14 feet round. It is, however, best planted by itself, though a stray giant here and there may well diversify the park or pleasure.

But if late leafing disqualifies the Ash for vicinage to the mansion and its wings, no such charge can lie at the door of the English Elm, which, coming late into leaf, is one of the latest of forest trees to succumb to autumnal frosts. A doubtful native, it must have been acclimatised, if at all, in the days of the Heptarchy, and since then has contributed more than any other tree, save the Oak, to the charm of rural England. In the valley of the Severn it has been so long naturalised that neighbouring counties distinguish it as the “Worcestershire” Elm; and though its introduction to Ireland, Scotland, and the Border belongs to a comparatively definable period, it may be said to have found a home in the south of England from time immemorial. That its form and growth with us eclipses that of Continental Elms appears in the fact of its having been exported from us to Spain to form the avenues at Madrid and Aranjuez in the reign of Philip II. It is probable that English avenues have been decimated in number through an absurd craze which possessed proprietors in the early part of this century to make war upon straight lines and double rows; yet wherever, as at Oxford, Cambridge, and here and there in the West of England, the old Elm avenues of two hundred years ago still survive, they assert a superiority in this fashion to avenues of Beech or Lime, or any other deciduous tree. To modern experiments in avenue-making with coniferous subjects—*Araucarias*, *Deodars*, *Wellingtonias*—there must ever be this drawback, that such double columns can never be in undress; whereas the Elm array is stately and impressive when off duty in the leafless season, just as it is gay and glancing, a mass of shade and shelter wonderfully disguised, when on parade and in full foliage. As much may be said for it in groups of two and three, or in the wilderness, which is a common feature of manor-house precincts. And it is indisputably the finest park timber after the Oak, in respect no less of its massy proportions than of the loose set of its crowded but small leaves, the cheerful green of which deepens as the months wane, till at last it becomes a clear yellow. Not every day, of course, does the tourist come across such Elms as the “Crawley” or the Hatfield, or such as are seen at Sion House or Longleat; but a girth of 14 or 15 feet at 5 feet from the ground is not uncommon in a kindly soil—to wit, a free, open loam, without stagnant water. An Elm at Croft Castle, Herefordshire, is 120 feet in height. After eighty years

\* But the common Oak has its pendulous variety, a famous instance of which is the Weeping Oak at Moccas Park, Hereford; the acorns of which, if planted, generate Oaks of more or less weeping habit. Loudon figured this tree in his “Arboretum.” Its girth at 5 feet from the ground is now 14 feet 3 inches, but though several of its branches still justify its distinctive name, the upper branches now take so much of the normal character of the Oak as to be somewhat disappointing.

the Elm has a tendency to become hollow, but this may be mostly where the soil is not deep and kind, and where the wet stagnates. Its worst foes, after wet, are the Elm beetle (*Scolytus destructor*) and the caterpillar of the gold moth. Its timber, valuable for many country uses, is eminently so where durability under alternations of wet and dry is a consideration—e.g., for pumps, troughs, conduit-pipes, water-gates, and water-wheels. It is in request, too, in dockyards for laying the keels of large ships.

Larger, broader, and more deeply serrate of leaf, though, like all the Elms, its leaf is unequal at the base, less upright, too, and stately in growth, though its spreading head, divergent limbs, and festoon-like branches render it highly picturesque in park or paddock, is the Wych or Scots Elm, an undoubted native of Britain, whatever be the history of its sister we name the English Elm. Whilst the latter carries its upper branches cluster-wise, and resembles a goblet in its tree-top, the former assumes a rounder and more umbrageous character, striking the critical eye as more easy and graceful. Another difference is that it has no suckers; another, that whereas the English Elm has to be propagated in this country by layers or suckers, the Wych is easily grown from seed. To see it in its glory probably the tree-fancier must go north: for the famous "Trysting Tree" near Roxburgh in Teviotdale (girthing 30 feet at 4 feet from the ground), and the Wych Elms of Eastby near Richmond in Yorkshire, eclipse in size the average Wyches of the south and west. Yet an exception may be made in favour of one near Chepstow Castle, which girths 36 feet at 4 feet from the ground; and we believe there is one of yet larger circumference in Lord Bathurst's park near Cirencester. Both of these put forth huge lateral arms. But the secret of the Wych attaining large proportions is a rich alluvial soil where moisture percolates freely, a reason, as Selby has noticed, for its affecting the Yorkshire river dales. Its name, we suppose, is no longer a puzzle, as the notice of its connection with magic arts sprang clearly from a fallacy of the ear. The Wych or Wiche Elm, is so called from the olden use of its wood to make boxes and chests, for which it was the old English word. It is said to have more toughness of longitudinal fibre than the English Elm; and is used for cart-trams, naves, and framing, and indeed, for most purposes for which the Ash is in request. Among its curious properties is its sure indication of coming frost. Unlike the common Elm, which keeps full late its deepened verdure, the Wych no sooner scents the advent of cold weather than it curls up its leaves, puts on a habit of brown, and anon is bare and leafless. For this and its singular retention of moisture, no less than its columnar trunk and finely reticulated bark, the Wych is a tree to plant and prize in the open; though the day is past when it might be used for a nurse, or clipped and maimed, as in the days of Queen Bess, for topiary purposes. Amongst its varieties the most attractive is the Camperdown (*Ulmus montana pendula*), a weeping Elm of singularly graceful habit. Most varieties are grafted on the Wych stock; and though Selby (p. 133) doubts the wisdom of trusting the *Ulmus campestris*, where the soil is good, to any stock but its own, we have ourselves seen the value of the grafted Elm in replacing the gaps of an Elm avenue. Compared with other makeshifts, its rapidity of growth fills a vacancy creditably in less than a score of years.

Like the Wych in roots that resist wind and storm, and like it in being among the first of trees to yield its leaves to the cold, the Lime or Linden (*Tilia*) is a foster sister of the English Elm, in that it frequently ekes out the avenues of the latter. The question of its indigenity is so far settled that the weight of authority leans strongly to the affirmative as regards the small-leaved Lime, which, as Mr. E. Lees, F.L.S., of Worcester, long ago noted, is common in the woods of Worcestershire, Herefordshire, Gloucestershire, and Oxfordshire. He testifies, also, to its seemingly indigenous presence on the banks of the Hefse, in Glamorgan; and draws a distinction between this and the *Tilia europæa*, which may have been introduced to England, for avenue purposes, in the days of William and Mary. This is seen chiefly in parks and gardens; while the rarer *Tilia grandiflora*, of larger leaf and a pale downy underleaf, is a denizen of the arboretum. A symmetrical tree in either variety, the Lime deserves the favour of the planter, singly, as well as in lines and rows. A single Lime at Long-leat measures 130 feet in height, its girth at 4 feet being 13 feet; but this is outvied by one at Moor Park, Herts, which girths 23 feet at the same distance from the ground, though its height is less by 30 feet. A more remarkable Lime still is to be seen

at Knowle in Kent, a rival of the Banyan tree in singularity of growth. Its lower branches have dropped till they kissed the ground, and thus taking new life, thrown up a circle of young trees from the parent stem. Aye, and repeated the process! The marvel repeats itself in a second circle; and this goodly company of attached and incorporate descendants of a living vegetable patriarch is said to cover a quarter of an acre. A like phenomenon is to be seen near the Roman remains in Lydney Park, Gloucestershire, where the small-leaved Limes, which are very abundant, give indications of great age, and may have been independent of man's planting.—(*Quarterly Review*.)

### THE THOMPSON FUND.

As several inquiries have been made regarding this fund it may be desirable to say what has been done. The sum of £90, or very nearly that, had been subscribed, and it was our hope that we might have been able to procure the admission of the two little girls into an orphanage, but after seeking in all directions we were compelled to abandon this notion. Amongst others application was made to Mrs. Tait to obtain admission into her orphanage at St. Peter's, Thanet, but there were certain rules which interfered with their admission; but it was suggested by Mrs. Tait, that as the mother was living the most natural thing would be to allow her a certain sum monthly out of it on condition that the children were sent to a good school. This has been adopted, and the amount after paying funeral expenses will be so appropriated. The widow has been for some time receiving £2 a-month on these terms, and at this rate it will be a help to her for some years to come. Dr. Hogg has kindly undertaken the trouble of seeing to the distribution, and I have only now to thank those who contributed for the aid given in memory of one who was so justly respected.—D., *Deal*.

### NOTES AND GLEANINGS.

WRITING in reference to WALL FRUIT Mr. W. F. Radclyffe states that "for a long time, through the excessive drought and heat, Peaches and Nectarines seemed stopped in their growth, although they were kept watered. We have had a wonderfully fine rain, and the fruits are now swelling freely. I cannot remember such sultry suffocating weather as we have had this summer."

—MR. J. T. PEACOCK, Sudbury House, Hammersmith, has kindly announced that his collection of SUCCULENTS may be seen by visitors on any Tuesday from ten to four o'clock during August and September. Mr. Croucher, the gardener, will be in attendance.

—THERE is now in flower at Mr. Reeves', North End Lodge, Walham Green, a very handsome plant of *CRINUM GIGANTEUM*. It has a fine head of bloom, with about a dozen Amaryllis-shaped flowers of a very delicate blush colour. The flower stem is about 2 feet in height. This is probably the finest plant in the country—a charming acquisition for the conservatory at this time of the year. The plant may be seen by applying to Mr. Chapman.

—WE are glad to state that the DISASTROUS FIRE at Messrs. Boulton & Paul's will not affect any other department of the works, where business will therefore be carried on as usual; and although the horticultural workshops are destroyed, fortunately the entire stock of well-seasoned timber which was stored in sheds at a distance from the scene of the fire was saved. We are informed that arrangements are being made to resume this special branch at the earliest possible date, and continuing it during the rebuilding of the premises.

—MR. JACKSON, gardener to Lord Scarsdale, Kedleston Hall near Derby, has an EXTRAORDINARY CROP OF GRAPES, one Vine carrying about 154 lbs. of very fine fruit, the bunches averaging about 3 lbs. each. They are Black Hamburgs. They are very noteworthy, and bear the evidence of skilful culture.—E. C.

—IN the report of the Sawbridgeworth Nurseries on p. 121 it was inadvertently stated that Mr. Rivers possessed a stock of MRS. PEARSON GRAPE. Mr. Rivers requests that the mistake may be rectified, that Grape being now announced for distribution from the Chilwell Nurseries.

—SOME of the finest MUSCAT OF ALEXANDRIA Grapes that have come under our notice have been grown this year by Mr. Denning at Londesborough Lodge, Norbiton. The berries are

remarkable for their size and regularity, being 1½ inch in longitudinal diameter, and they are highly finished. The Vines in this garden are young and in admirable condition, and are fully as noteworthy as are the many fine examples of Orchids for which this place is famed.

— THE APPLE attains a large size in Nova Scotia, and in favourable seasons is of fine flavour, well ripened and coloured. This is owing largely to the beautiful autumn months of September and October—the heat of the sun and the warm dry weather being almost peculiar to the climate at this season of the year. The recorded weight of several varieties exhibited at the shows of the Fruit-Growers' Association is as follows:—

	Dozen.	Single Specimen.
Gravenstein .....	7 lbs. 9 ozs.	18½ ozs.
Ribston Pippin .....	6 " 14 "	9½ "
Yellow Bellefleur .....	7 " 10 "	11 "
Baldwin .....	7 " 10 "	12½ "
Gloria Mundi .....	10 " 7 "	20 "
Obenbuck Beauty .....	9 " 7½ "	18½ "
Emperor Alexander .....	9 " 3 "	18½ "
King of Tompkins Co. ....	6 " 14 "	11 "
Northern Spy .....	8 " 6 "	12 "

The Apples for winter use and for commercial purposes are taken from the trees in the month of October, and from the 5th to the 25th, and sometimes even later. The early sorts, such as Red Astrachan, Early Harvest, Early Joe, Early Red, Bough and Sutton's Early, a native of Nova Scotia, ripen in August and September; then come Porter, Williams' Early, Munson's Sweet, and Gravenstein in the month of September and early in October, the Gravenstein often attaining its greatest perfection when left on the tree as late as the 5th and 10th of October. The Baldwin, Greening, Nonpareil, Russet, Northern Spy, King of Tompkins County, Blue Pearmain, Yellow Bellefleur, Ribston Pippin, and other varieties do not attain their perfection till the 10th to the 25th of October.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### HARDY FRUIT GARDEN.

THE pyramid and dwarf-trained trees have until now not been interfered with. They would have been looked over and all superfluous wood removed, but a press of other work prevented it. We are now cutting out all the young wood that is not required, leaving only two or three buds at the base of the shoots. Some of the Pear trees, and also a few Apple trees, have made a large quantity of young wood, and trees planted only 6 feet apart had grown into each other. There is a great difference in the quality of the soil for causing trees to grow to wood buds. Our experience is that light soils have a greater tendency to produce young wood than heavy or clay soils. We have seen the young trees at Sawbridgeworth grafted on dwarfing stocks make but little growth in a young state, producing far more fruit than leaf buds, and when the same trees were removed to a light moderately rich soil they produced young wood too freely.

Constant summer pruning and pinching will cause the production of fruit buds in many instances; but it is sometimes necessary to supplement this with root-pruning. For instance, we have not been able to repress the vigorous growth of Waltham Abbey Seedling or Tower of Glamis Apples by any system of pruning, and equally difficult has been the management of General Todtleben and Maréchal de Cour Pears; but cutting back the roots in autumn as an aid to summer pruning is generally sufficient. The hot summer weather has developed an unusually large number of the Apple maggot. As the trees are being pruned all fruit that has been bored by the maggot is gathered from the trees, in order if possible to diminish the numbers of the pest in future years. Removing the young wood has allowed the influence of light and air to act upon the fruit. Apples, Pears, and Plums are very much below the average of previous years. Bullace trees, which have not failed to produce a crop during the last twelve years, are a total failure, and the same may be said of Damsons. Raspberries were a good crop, and they are making strong young wood for next year. Cherries and Red Currants were good crops, and Gooseberries were up to the average.

Strawberry plants put out a month ago are now making vigorous growth. It has been necessary to look over the plants and to cut away the runners. In a week or two it will improve the plants to run the Dutch hoe through between the rows. We have noticed on wall trees, especially this year, a number of branches on Plums, Peaches, and Apricots that have died off. The dead or decaying leaves are unsightly, and the branches ought to be removed, laying the fresh growths from each side closer together to fill up the vacant space. Any trees that have suffered from drought now show the effects of it by the fruit

dropping off after a good soaking of rain. Morello Cherry trees require but little pruning; they have carried a very good crop of fruit this year. When the wood is too thick the present is a good time to thin it out.

### VINERIES.

It is too early to prune the Vines in the houses intended to be started about the end of November. The top lights should be pulled down night and day, and the front sashes be open to their fullest extent. All lateral growths should be stopped as they are formed. The late Grapes are not yet ripe, but with a night temperature ranging from 55° to 63° we do not think it necessary to apply artificial heat. The ventilators have been opened to their fullest extent by day owing to the intense heat, the thermometer having risen in the shade on many occasions over 90°, once to 95°. A little air is admitted all night both at the front and back of the houses. The temperature has now fallen considerably, and a fall of 0.72 inch of rain has cooled the ground, and it will doubtless gradually become colder. In northern districts it may be necessary to apply artificial heat to the Muscat house; with air on the night temperature should be about 70°, rising about 10° higher in the day from sun heat. North of the Forth in Scotland and in some of the wet districts of England it is necessary to use artificial heat all through the summer months for Muscats. The atmosphere is kept rather dry and the ventilators are constantly open; a very small chink of air will keep up the circulation.

Vines in pots that have not yet ripened their wood must be encouraged with a high temperature, and if the growth is over-luxuriant water must not be too freely applied to the roots. When in full growth and when the pots are well filled with roots a very large quantity of water is absorbed; but we have not always found the strongest canes bear the best fruit; moderate canes with prominent buds generally give the most satisfactory results. Early-ripened canes intended for early forcing should be kept moderately dry at the roots. It is a great mistake to dry them off, thinking that the wood will be ripened in that way. It does not follow that because the wood is brown that it is necessarily ripe. The main object of the cultivator is to produce well-developed buds. If the pots have been placed in front of a wall facing south, or where they are fully exposed to the sun, a slate, tile, or board should be placed against the pots to prevent the heat injuring the roots.

### MELONS AND CUCUMBERS.

Late Melons will now be flowering, and a temperature of 65° at night should be kept up, rising considerably in the day. Close the house early, and syringe freely to keep the plants free from red spider. Melons in frames are liable to suffer from damp after this month. The fruit should be laid on a bit of tile, but it should also be partially shaded by the leaves. Melons under glass fully exposed to hot sunshine not unfrequently receive injury before the fruit is ripe.

It is now a good time to sow Cucumbers for an early winter supply. They come into bearing early in October, and will, if not overcropped, continue to produce Cucumbers till March. After that time it is best to trust to plants raised from seeds in January. It is a great mistake to allow the plants to bear too much at any time during the winter months; it checks the development of young growths, and the plants take a long time to recover.

### PLANT STOVE AND ORCHID HOUSES.

There is no potting required at present, but all plants that have sufficient rooting space make vigorous growth during the next six weeks. It is well to see that this growth does not become overcrowded. One not unfrequently sees the young wood, or rather the growing shoots, bundled together so that it is impossible that any of them can be well ripened. To give stove climbing plants anything like justice they ought to have sufficient space. One growth that has been exposed to light and air is worth any number of immature shoots which the sun has not reached. It is a good time also to destroy mealy bug. This must be washed off with a sponge and soapy water. Thrips are also very active, and they attack plants that are quite free from bug. They prefer the younger leaves, and when they attack the centre of the young growths it is very difficult to eradicate. Red spider has also been very active during the hot dry weather, especially on Dendrobiums, such as D. Devonianum, D. Bensoniae, and other sorts. Daily syringings are needed to keep such Orchids in good health.

Flowering stove plants that are being grown-on for decorative purposes in the winter require careful attention; they should be trained into proper shape and kept free from insect pests. In order that such plants as Euphorbias, Aphelandras, Eranthis, Thysanacanthus, &c., may flower freely the plants must after this be freely exposed to light and air. Poinsettia pulcherrima is generally grown in too much heat through the summer months; the plants make the most satisfactory growth in a cool greenhouse, or in a sheltered position out of doors. They must not be placed where they are exposed to the fury of south-west winds; in dry weather they must be syringed twice a-day. The general collection of Orchids require less water at the roots,

and light and air should also be freely admitted to them. Cool Orchids, especially *Odontoglossum crispum* and the *Masdevallias*, require a larger supply of water than any other species. We generally place them during the growing period together in the house, so that they may be syringed overhead once or twice a-day in hot weather.

#### FLOWER GARDEN.

We have not yet commenced putting in cuttings of the tricolor-leaved *Pelargoniums*, but it is now time that this was done, and all the slow-growing varieties will be put in as soon as possible. The best way is to put the cuttings in pots or boxes and place them out of doors. They will strike freely if the weather continues warm; cold and wet are injurious. Roses are liable to the attacks of mildew more at this season than at any other, and if this pest goes on unchecked for a time it is very difficult to remove it. On its first appearance the affected parts should be dusted with flowers of sulphur, or the bushes may be syringed with water in which 1 oz. of soft soap and 2 ozs. of sulphur to the gallon have been dissolved. After the bushes have been cleaned from the pest, and should the weather continue dry, syringe freely in the morning and water the roots, giving a slight mulching of manure over the surface of the ground.

In the course of this or next week the early-flowering pot Roses will be repotted. This is done annually at this time of the year. The Rose delights in rich sweet soil, and to be successful in pot culture it must be renewed annually. The pots are well drained, and some fibrous loam is placed over the crocks to keep the finer soil from mixing with them. Truly loam five parts, one of decayed manure, and one of leaf mould, grows them well. After potting the plants are placed in an open position out of doors.

Owing to the very hot dry weather when the Pink pipings were put in, we have had to put in a second lot to replace some that have failed; at this season they will root freely. Carnations and Picotees have all been layered and are making very strong growth. The surface soil is just sprinkled with water when it appears dry. Auriculas are throwing out offsets freely this autumn. When large enough they will be taken off and potted in small pots. We look over the plants once a-week to remove weeds, decaying leaves, caterpillars, and insects.—J. DOUGLAS.

#### TRADE CATALOGUES RECEIVED.

Sutton & Sons, Royal Berkshire Seed Establishment, Reading.—*Illustrated Autumn Catalogue of Bulbous Flower Roots, Plants, Seeds, &c.*

Dickson & Robinson, 12, Old Milgate, Manchester.—*Catalogue of Dutch Flowering Bulbs, &c.*

James W. Mackey, 40, Westmoreland Street, Dublin.—*Descriptive Catalogue of Dutch Flower Roots, &c.*

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

LARGES AND FAIRLIE. August 25th. Mr. D. G. Glen, Hon. Sec.  
SANDY. August 25th. Mr. E. T. Smith, Hon. Sec.  
SEATON BURN. August 26th. Mr. B. Richardson and Mr. W. Elliott, Sees.  
DOVER. August 29th. Messrs. E. W. Fry and C. T. Whiteley, Hon. Sees.  
CHIPPENHAM. (Cottagers' Garden Improvement Society). August 29th. Mr. Alfred Wright, Sec.  
ISLE OF THANET (MARGATE). August 30th. Mr. C. D. Smith, 8, Marine Terrace, Margate, Sec.  
SHIRLEY, MILLBROOK, AND FREEMANTLE. August 30th. Mr. Jennings and Mr. Squibb, Hon. Sees.  
POCKLINGTON. August 31st. Sec., Mr. J. E. Ross.  
YARMOUTH. August 31st. Mr. S. Aldred, Hon. Sec.  
THORNTON HEATH. September 1st and 2nd. Mr. W. Raines, 10, St. John's Villas, Bensham Manor Road, Thornton Heath, Hon. Sec.  
MONTROSE. September 1st and 2nd. Mr. Alex. Burnett, 2, High Street, Sec.  
STAMFORD. September 7th. Entries close September 2nd. Address the Hon. Sec., Stamford.  
DUNDEE (International). September 7th, 8th, and 9th. Mr. W. R. McKelvie, 26, Euclid Crescent, Sec.  
GLASGOW. September 12th and 13th. Mr. F. Gilb. Doughall, 167, Canning Street, Sec.

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

MUSHROOM CULTURE (*R. Goodchild*).—Full directions are in "The Cottage Gardener's Dictionary."

VINES MILDEWED (*An Anxious Inquirer*).—As the berries also shank, we think the roots have much to do with the disease. Cut away the descending roots, and keep the surface of the border moist. We do not consider such a house and site as you describe favourable for the production of good Grapes.

BORAGE TEA (*A Lady*).—The Borage is taken green, and the foliage, stems, and flowers are boiled or infused.

FLOWER STAND (*A. J. M.*).—We cannot supply what you require.

MINT BROWN (*E. M. P.*).—If you water it freely and regularly during this dry hot weather the leaves will not decay. The beetle will do no injury of consequence.

BLACK BEETLES (*T. F. H.*).—Try Chase's pills for destroying them. Place one or two pills on the surface of the soil in the Chrysanthemum pots. The pills are sold by chemists.

DR. MACLEAN PEA (*A. S.*).—This is a very fine exhibition Pea. It has fine pods, which are closely filled with Peas of excellent quality. Commander-in-Chief is also one of the finest of Peas for the exhibition table.

PERENNIAL BORDER (*A. N.*).—Read Mr. Luckhurst's article on page 160 of the present number, which will probably give you the information required.

FRUIT TREES FOR ORCHARD PLANTING (*Leeds*).—The best Apples are—Alfriston, Bedfordshire Foundling, Bess Pool, Blenheim Pippin, Brownlee's Russet, Cellini, Pomona (Cox), Devonshire Quarrenden, Dumelow's Seedling, Emperor Alexander, Golden Noble, Kerry Pippin, Keswick Codlin, London Pippin, Orange Pippin, Norfolk Bearer, Reineette du Canada, Rymer, Tower of Glamis, Waltham Abbey Seedling, Winter Pearmain, Sturmer Pippin, and Wyken Pippin. Pears—Autumn Bergamot, Beurré de Capiaumont, Bishop's Thumb, Croft Castle, Eyewood, Hessel, Louise Bonne of Jersey, Suffolk Thorn, Swan's Egg, Williams's Bon Chrétien, Windsor, Winter Nellis, and Doyenné d'Été. Plums—Early Rivers, Orleans, Mrs. Gibborne's Goliath, Mitchelson's, Victoria, Diamond, Belle de Septembre. Cherries—Elton, Knight's Early Black, May Duke, Morello, Kentish Bigarreau, Governor Wood, Duchesse de Palluau, and Late Duke. If the soil is moderately rich it is better not to manure the ground for the trees you name. October and November would be suitable months to plant Rhododendrons and Hollies.

BRANCHES OF PEACH AND NECTARINE TREES DYING (*Neworth*).—The leaves sent are infested with red spider; besides, the leaves are thin in texture, showing that the house is not properly ventilated. Keep the leaves free from insect pests, and admit air to the house sufficiently to prevent scorching, and the branches will not die off.

PLANTING PERENNIALS (*Ladie*).—You may plant them as soon as the heat of summer has subsided and the autumn rains commence falling, or any time from September to November when the weather is dull and showers are prevalent. You can do nothing at the present time by way of remedying your unsightly-pruned Roses. Probably the shoots left will become matured, and they should be rather closely pruned about March or April next, and new shoots may be produced to give you a fair supply of blooms.

COCKSCOMB CULTURE (*X. Y. Z.*).—The seed should be sown in heat early in spring, and when large enough the seedlings should be potted singly in small pots. In these they should remain until they show the "heads," and the most promising plants must be repotted into larger pots, and be still grown in a heated house or frame, a Cucumber frame answering very well. The soil must be light and rich; loam, leaf soil, and decayed manure in equal parts, and a liberal admixture of sand answering well. The plants should not be planted out before July. March or April, according to convenience for growing the plants on, would be a suitable time for sowing the seed.

VIOLAS (*Arthur Loftus*).—The best half-dozen of Violas in their improved forms are Crown Jewel (Dean), yellow; Lothair, indigo blue with dark blotch; Royal Blue (Dean), clear blue; Alpha, bluish purple; Lady Susan, golden yellow; and Golden Perpetual. There is no really good white Viola; but Deau's White Bedder, a Fanny, is good. They are all hardy. The cuttings may be put in a sheltered situation early in October and planted out in spring, or they may have the treatment of bedding *Calceolarias*. The *Tropaeolum* you saw in Scotland is probably *T. speciosum*. Plant it out, if you live in the south, in a bed of peat soil, and allow the shoots to grow over Rhododendrons or similar shrubs: in this way it is a choice "weed." Or if north, plant against a wall with a west or south-west aspect, watering freely in dry weather, and training to a trellis.

VINES ATTACKED WITH MILDEW (*T.*).—Give a little fire heat so as to admit air more freely, continuing until the Grapes are ripe, and dust the parts infested with flowers of sulphur. Discontinue the application of soapsuds, and keep the atmosphere dry by free ventilation.

NAMES OF FRUITS (*Connaught Subscriber*).—1, Lucombe's Nonesuch; 2, Red Magnum Bonum. (*C. M. A.*)—Florence Cherry. (*Ewing & Co.*)—The Apple is very like Sack and Sugar except in flavour, and in that respect it is not so good. It has a strong resemblance to some of the Russian Apples. (*Fitz*).—1, Mère de Ménage; 2, Rosemary Russet; 3, Hawthornden; 5, Loan's Pearmain.

NAMES OF PLANTS (*F. M. Rogers*).—*Geranium striatum*. The wild Parsley is very peculiar. (*J. D.*)—*Geranium phaeum*. (*H. T. B.*)—1, *Scutellaria Mocquiniæ*; 2, *Ligustrum japonicum*; 3, *Ceanothus azureus*; 4, *Buddleia globosa*. (*Constant Reader*).—1, *Buddleia asiatica*, or a nearly ally; 2, *Achillea ptarmica*, double-flowered var.; 3, *Polystichum angulare*; 4, *Lastrea dilatata*; 5, *L. spinulosa*. (*G. Copstock*).—*Spiræa arifolia*. (*James*).—You are probably right, but the specimen is not satisfactory. (*A. Wildsmith*).—*Polygonum Convolvulus*. (*L. J. K.*)—A double-flowered variety of *Convolvulus* (*Calystegia*) pubescens. (*Johnson*).—1, *Abutilon striatum*; 2, *Lophospermum erubescens*; 3, *Veronica speciosa variegata*; 4, a *Davallia*; 5, *Clematis viorna*; 6, *Tradescantia zebrina*. (*J. H.*)—1, *Hedychium Gardenianum*; 2, *Griffinia hyacinthina*. (*G. R.*)—*Epilobium lanceolatum*. (*I. A. M.*)—The yellow flower is *Lysimachia vulgaris*, the other *Lychnis Haegiiana*. Your other question will be replied to in a future number.

#### POULTRY, BEE, AND PIGEON CHRONICLE.

#### ADVERTISEMENTS.

WE believe it is Mr. Streeter who in his advertisements states that advertising is to trade what steam is to machinery, and so in the poultry world an advertisement often is the means of clearing off a lot of fair birds at a remunerative price; but then the advertisement must be drawn up in such a way as to state fully and truly what is for sale, and in a manner easy of being understood. But some advertisements we cannot understand.

We will give one or two examples. "One of the best Brown Red cocks in England, two years old, stand death," recently appeared as an advertisement. Now we ask, What does this mean? Is it that the said Brown Red bird will stand, and not be in any other position when the cruel hand of death overtakes it? or is it that it is cat-like and rejoices in many lives, only one or two of which have been lost when the bird is offered for sale? or is it that it is invulnerable and will live on for ever? or what does it mean? We confess we are confused, and fear the Brown Red must be still for sale. Here is another—one, however, almost as mystifying: "Spanish cock, nearly blind, with white, and one hen have prized;" but whether the advertiser considers that the Spanish cock in question to have been perfect should have been quite blind with white or partially so with any colour, or whether the blindness spoken of in a fit of desperate honesty, and the cause of the blindness merely added as a sop, we cannot determine. Anyhow, the partially blind cock which "has prized," will, we fear, hang on hand. The next column, however, provides us with an absolute bargain. Imagine fowls at 4d. each, for we read in this thrilling advertisement, "Three fowls for 1s." There is a delicate silence as to the breed, age, and general minutiae, but for such a bargain the world must be clamorous, and we hope the three fourpenny chicks were not so young as to die *en route* to their new home. Just above that, however, we read that there is someone in London (of negro extraction we should almost think), who with a fresh and wholesome mind wants white things around him. Dorkings, Spanish, Cochins, and Brahmas are offered for exchange, but the offers must be "white." Does the advertiser when he puts "white offers" expect to be deluged with offers of people and things from other countries? or can "white" be a misprint for "write"? But surely this is improbable, for no one can imagine that these birds would be sent for by special messenger or by telegram. One more quotation and we have done. "Three hens, three cocks, twelve pullets, and a cockerel." "Must be sold before Wednesday." The day we are writing on is the actual Wednesday, and we cannot help wondering if the nineteen birds have found a new home. We should be afraid not, for only three clear days, and one of those a Sunday, were allowed for this speedy sale; and as neither the price was given, nor the address of the advertiser, some sort of correspondence would necessarily have to ensue. The above is a type of advertisement which is sent out to the world. We are sure advertisements cannot be drawn up too plainly or too fully, for people feel much more inclined to answer an advertisement which will not necessitate much correspondence, and which states directly what is for sale, than they do those which simply state the name of the article and give no particulars or prices.

There are the advertisements, too, of forthcoming shows and meetings, which are not nearly plain enough; for instance, some little town which is not well known gets up a poultry show and advertises it, but never states the county it is in, and consequently exhibitors do not take the trouble to write for schedules, thinking it may be in some inaccessible place. Very likely the town has no station, and is dependant on that of a neighbouring place, and so the "Bradshaw" can give no help. Only this week we attended a show which in its advertisement never stated the name of the county the town was in, and as it had no station we heard afterwards of two exhibitors who would have exhibited had they known where the place was. We could find nothing to direct us as to its stations, and when we arrived we found ourselves separated from the exhibition by a cab fare of 11s. We would urge on all advertisers, especially those of "coming events," who to a great extent depend upon the public for their support, to be very particular in describing their county when the place is not generally known, and even to state on what line of railway it is situated, and what are the best trains and stations. The small sums the extra words in the advertisements would cost them would be amply repaid by increased entries and support.

Advertisers cannot be too sufficiently accurate in the truth of their advertisements. Of course, no papers will be responsible for the truth of statements any more than they will be of the trustworthiness of the buyers and sellers; but statements, often made for want of thought, place advertisers in disagreeable positions, for there will always be found some ready to think the errors were done purposely. We noticed in a contemporary last week an advertisement about an illustration which was stated to have appeared in its columns, but which we believe never did, for it belonged to another journal entirely. We do not doubt but that this error was made by want of thought simply, and yet we learn that there was someone ready to "catch up" this advertiser and to proclaim him in the wrong. This statement was, however, made in such an open sort of way that we can but believe the advertisement was drawn up by mistake, and not done so to gain honour for the birds, which notice and illustration in the contemporary in question would have gained them. Many are the advertisements of the nature we have quoted from, and we could give instances of some even yet more abstruse, but we have told of enough, we

hope, to put our readers on their guard against ever compiling such foolish compositions.—W.

## OLDHAM SHOW OF POULTRY, &c.

THIS year we are happy to relate the Oldham Show was held under more favourable circumstances than was that of last year, for though showers fell at intervals the day was tolerably fine; in fact there was no impediment to the influx of visitors. Turner's pens were used on this occasion and placed in the open air; the sky breeze seeming to chill some of the Pigeons, which were more unluckily placed than the poultry, which had the fence to shield them.

The Show was for young birds of this year in the poultry section, and being the first of the season great interest was manifested; our experience leading us to believe that great size is not to be a striking feature of this season's produce. Some of the classes were very weak, and from the Brown Red chickens that won in the first class we found nothing of great note till we came to the *Cochins*, in both classes of which were some excellent birds; the first-prize Buff pullet was almost as high in colour as a well-peppered Canary. Next to these were the Gold-spangled *Hamburgs*, among which were pullets almost equal to hens in point of spangling, and in our opinion an improvement on all previous years. Black *Hamburgs* were really grand, the plumage of some of the pullets being almost like polished metal. *Bantams*, Game pretty good, and Black very good. The *Ducks* in both classes large and well forward in feather.

*Pigeons* were a larger entry than the poultry, the local classes assisting greatly in enhancing the interest in the Show. Carriers had two classes. In cocks Mr. Walker's champion Blue was left out. In hens, first was a grand Dun, but we thought Mr. Walker's Dun should have been second. The best birds in the Turbits were left out. Pens 630 and 632 should have occupied their position, the winners being very foul-thighed—a point that no doubt escaped the notice of the Judge. Jacobins and Fantails were placed, as also foreign Owls, which were good. In Blue and Silver Dragons the greatest mistake occurred, the first going to a bad White Carrier. The same exhibitor's Silver should have been second, and Mr. Wood's Silver first. Any other colour were well placed; first Yellow and second Red. Antwerps were a good entry, the young class producing some wonderful birds.

*Rabbits* had twenty-eight entries in seven classes. In Lop bucks first was a Black-and-white, rather bad in colour and thin, but by far the best in other points; second also Black-and-white; and third Sooty Fawn; an otherwise good Blue was very crooked in leg. In does we were surprised to see so much improvement in Messrs. Schofield and Barrett's Black doe, left out at Idle for badly-cankered ears, and she was consequently placed first; second was the same exhibitor's Fawn-and-white; a third prize was awarded, but this was to a very crooked-legged Rabbit. Dutch were pretty good; the first a very promising one, not so good in blaze as the second, but more evenly cut. Angoras were good and fine in wool, and Himalayans a nice lot. The Silver-Gray winner at Idle was again first here, and has without doubt one of the best coats of fur of any Rabbit living; the rest very good specimens. The Variety class had Belgian Hares, but they were poor.

**POULTRY.—GAME.—Black-breasted and other Reds.—Chickens.**—1, T. Dyson. 2, J. F. Walton. 3, W. A. F. Fenwick. *Any other colour.*—1, Ambler and Hartley. 2, T. Dyson. *SPANISH.—Chickens.*—1 and 2, J. **JUDGES**.—Messrs. Teebay and Hutton.

## MALMESBURY POULTRY SHOW.

THIS SHOW, which was held on the 17th inst., is one of those which improves annually. It began six years ago with just a few pens, and this time there were nearly two hundred pens of really good quality. Mr. John Martin again awarded the prizes, and his awards were very favourably received. The immense distance of Malmesbury from the station is a great drawback to the Show, and though a new line is in course of construction it seems a long time in progress. The birds were under a spacious marquee, and the pens (Turner's) were well littered with chaff. The gems of the Show were, in our opinion, the Buff pullet in Mrs. Allsopp's pen, the Light Brahma pullet in the Marden pen, and the first Rouen Ducks.

*Dorkings*, which came first on the list, were only a moderate lot, they being old birds and mostly out of feather. *Spanish* only made three pens, but all good; adults in good plumage first, and promising chickens second. *Game* were few, and nothing worthy of comment among them. In *Cochins* a good pen of Partridge (adults) were first, both in good plumage, and as a pair we thought them almost the best in the Show, and would have felt inclined to come here for the cup for the first eight classes; second went to Buff chickens, and though the pullet was simply perfection, the cockerel was such a wretch, and had his wings in such a mess, that we would have passed the pen. In *Dark Brahmas* the second were in the best feather, but the first were the largest. In *Lights* the first pullet was extremely good in every way, but the cockerel was small and inclined to yellow. This pen won the cup, and it was certainly here or to the Partridge *Cochins* it should have come. Perhaps it is fair to give the preference to well-grown chickens at this season of the year. Second went to much younger but good chickens. *Hamburgs* were miserably represented; first were fair Blacks, second neat Silver-spangles. *Polands* only made three pens, and the first was again won by good White-crested Blacks; the cock rather yellow, but the hen the one we have so often commented on. Second and highly commended were good pens of Silvers, the second winning from being in better feather. The Variety class was good, capital Silky chickens taking first, and nice Malay chickens second; highly commended (Long) *Sultans* out of feather, and (Feast) good adult *Crêves*. *Game Bantams* were very moderate; first Pile chickens, second Duckwings. The next Bantam class was admirable; first splendid Blacks, second Silver-laced. Pen 11 (Mayo) contained exquisite Silver-laced chickens, but the pullet had a single comb. *Rouen Ducks* were good; the first pair were monsters, and deservedly won the other cup. *Aylesburies* fair, the winners soon claimed at £2 15s. In *Variety Duck* class very lustrous East Indians were first. *Geese* only made two pens, both Grey and both good.

*Pigeons* mustered fairly well, *Carriers* most especially. The Pigeon cup went to Mr. Yardley's black cock, and the award was correct. *Blue Pouters* were first, second going to *Whites*. *Fantails* were capital, and here is the only class we really differed with the awards, but even here the pens were very equal. In the *Variety* class the cup Hereford Red Turbits won second.

In *Rabbits* a fair black Lop, measuring in ears 20½ by 4½, was first. *Himalays* were poor, and only one prize was awarded. Good *Angoras* won in the *Variety* class both first and second prizes.

In *Cats* *Tabbies* were by far the best. The Long-haired only had three entries, of which we could only find one, and that was rightly deemed unworthy of a prize. A solitary Black won first in his or her class. We furnish full awards below.

**POULTRY**.—*DORKINGS*.—1, J. Gee. 2, G. Hanks. *SPANISH*.—1 and 2, Mrs. Allsopp. *GAME*.—*Black-breasted Red*.—1, E. S. Godsall. 2, H. Feast. *Any other colour*.—1, G. Hanks. 2, E. Winwood. *COCHINS*.—1, H. Tomlinson. 2, Mrs. Allsopp. *BRAHMAS*.—*Dark*.—1, Mrs. Radclyffe. 2, J. Long. *Light*.—Cup, Miss J. Adams. 2, E. Schammell. *HAMBURGS*.—1, J. Long. 2, H. Feast. *POLANDS*.—1, T. Norwood. 2, J. Long. *ANY OTHER VARIETY*.—1, Rev. R. S. Woodgate. 2, J. Horton. *BANTAMS*.—*Game*.—1, A. H. Horn. 2, J. Mayo. *Any other variety*.—1, L. G. Mortell. 2, W. Morris. *SELLING CLASS*.—1 and 2, Haddrell. *ANY VARIETY*.—*Cock*.—1, J. Loader. 2, B. Greenhill. *DUCKS*.—

## DURHAM COUNTY SHOW OF POULTRY, &c.

THIS annual Show came off at Sunderland on the 17th inst., when the entries for poultry, &c., were larger than on any previous occasion. The pens were arranged on the sides of a field in the open air, and the weather being fine the Exhibition was a success.

*Dorkings*, *Cochins*, and *Spanish* were small entries, but the winners good, the cup for section going to a capital pen of Buff *Cochins*. *Malays* of this season produced a good class, and the cup for several classes was carried off by the winning pen, which were unusually good. *French* poor except the *La Flèche*. *Red Game* were mostly old birds, but the first was awarded to a smart pair of Brown Red chickens, the cup going to a grand pen of Duckwings in the next class, which, if we mistake not, were the cup-winners at Otley. Gold-spangles an extraordinary class of old birds, and the cup for *Hamburgs* was awarded here. *Silver-spangles* a fair lot, the first-prize cock uncommonly white. Other *Hamburgs* were a little more shabby in plumage. *Polish*, first Silver, and second and third Gold. In the *Variety* class Black *Hamburgs* and *Silkie*s won. In chickens first, second, and third were Buff *Cochins*, and fourth Brown Red *Game*. *Bantams*, Black or other Reds, were a bad class, more on account of feather and condition than quality, and the variety class, though better, was little improvement upon it, while on the contrary, the variety class was a very good one, the first Blacks winning also the cup for the section, the second Whites, and third Silver *Sebrights*. *Bantams* of this season were a grand class; a very smart pen of *Piles* were first, and Black Reds won the rest of the prizes. *Aylesbury Ducks* were good, but *Rouens* better.

*Cats* as a rule were badly shown, many being entered in the wrong classes, the best of these being the first in the long-haired class.

*Rabbits* produced some fine animals—the Lop class very good; first a Black-and-white doe, on which we have often commented before; second a Fawn-and-white, 22 by 4½; the third a Fawn, 20 by 4½. *Angoras* very good and fine in wool; and *Himalays* a nice lot, and the winners very good in extremities. In the *Variety* class first was a well-known Silver-Cream, and third *Silver-Greys*, both good.

**POULTRY**.—*DORKINGS*.—1, T. P. Carver. 2, H. H. Cochrane. 3, W. Swann. *COCHINS*.—Cup, 1, 2, and 3, G. H. Proctor. *SPANISH*.—1, R. Shield. 2, H. Beldon. *BRAHMAS*.—1, R. Shield. 2, Anderson & Hewitt. 3, J. F. Smith. *MALAYS*.—Cup and 1, R. Hawkins. 2, W. A. Fairlie. 3, S. B. Perry. *FRENCH FOWLS*.—1, E. Walton. 2 and 3, C. M. Saunders. *GAME*.—*Black and other Reds*.—1, J. F. Walton. 2, J. Cook. 3, Holmes & Destner. *Any other variety*.—1, J. Nelson. 2, J. E. Walton. 3, J. Mason. *etc.*, Holmes & Destner. *HAMBURGS*.—*Gold-spangled*.—1 and 2, H. Beldon. 3, T. P. Carver. *etc.*, R. Keenleside, Holmes & Destner. *Silver-spangled*.—1, H. Beldon. 2, G. Alderson. 3, Holmes & Destner. *Gold-pencilled*.—1, H. Beldon. 2, T. P. Carver. 3, J. G. Walker. *Silver-pencilled*.—1, H. Beldon. 2, D. Clow. *POLANDS*.—1, H. Beldon. 2, T. P. Carver. 3, H. A. Clark. *ANY OTHER VARIETY*.—1, H. Beldon. 2, H. A. Clark. 3, H. A. Cave. *ANY VARIETY*.—*Chickens*.—1 and 2, G. H. Proctor. 3, G. Latimore. 4, J. Nelson. *etc.*, J. Nelson. *BANTAMS*.—*Black and other Reds*.—1 and 2, J. Nelson. 3, T. Dowell. *Any other variety*.—1, J. Nelson. 2, R. Brownlee. 3, T. Dowell. *Any other variety except Game*.—Cup and 1, R. H. Ashton. 2, E. Walton. 3 and *etc.*, Rev. H. A. Hawkins. *Any variety*.—*Chickens*.—1, R. Brownlee. 2, J. Nelson. 3, W. Wardle. 4, E. Walton. *DUCKS*.—*Aylesbury*.—1, E. Gibson. 2, M. Walker. 3, W. Stonehouse. *Rouen*.—1, W. Swann. 2, J. E. Moody. 3, J. Nelson. *SELLING CLASS*.—2, J. F. Walton. 3, J. Hudson. *GAME BANTAMS*.—*Undubbed Cock*.—1, T. Clark.

**CATS**.—*LONG-HAIRED*.—*Male*.—1, Mrs. Briggs. 2, A. McDougall. 3, T. Bell. *Female*.—1, E. Ward. 2 and 3, A. McDougall. *TABBY*.—*Male* or *Female*.—1, J. G. Froggett. 2, M. Nichol. 3, D. Stephenson. *ANY OTHER VARIETY*.—*Male* or *Female*.—1, J. Dixon. 2, T. Bostle. 3, L. Tyeddi.

**RABBITS**.—*LONG-EARED*.—1, E. Pepper. 2, J. Handlip & Son. 3, H. Greener. *etc.*, J. Edwards. *ANGORA*.—1, J. Stansfield. 2, J. W. Ibbotson. 3, C. Walker. *HIMALAYAN*.—1, W. Smith. 2, M. Fletcher. 3, T. & E. J. Fell. *ANY OTHER VARIETY*.—1, H. E. Gilbert. 2, T. & E. J. Fell. 3, J. S. Robinson.

The Judges were Messrs. E. Hutton and G. Hall.

## HEANOR SHOW OF POULTRY, &c.

THE fourth Exhibition of poultry and Pigeons was held in Heanor Park on the 15th inst. Grounds more beautifully wooded or adapted for gala purposes it would perhaps be difficult to find, and a splendid marquee with Turner's pens completed the provision for the birds that deserved a much greater display; but the great drawback to numerous entries was the enormous fee charged on each pen, a fee no one with an eye to making their hobby self-supporting would ever think of paying; but this and other matters are to be seen to another year, and with reforms of a practical kind we have no fear of the future of this Society. After all, the entries were much larger than in any previous year, and as an average the quality was high.

*Dorkings* headed the list; a splendid pen of Silvers standing first, with Greys second and third. In *Cochins* was one grand pen of White, the second Partridge, and third Buff. *Brahmas* a bad lot if we except the winners, which were Dark Greys. *Hamburghs* had but one class; first Silver-spangles, second Silver-pencils, and third Blacks, pretty good. *Game* were mostly out of feather, but though in sad plight we recognised some champions, notably the first Brown Reds and Duckwings. *Spanish* were all very good, also *Game Bantams*. *Game* a grand class; first an old pen of Brown Reds, small and gamey and good in colour; second and third small Black Red chickens. In *Game*, any other, all the winners were Piles, and extremely good. In the variety of Bantams first were Silver Sebrights, second White, and third Gold Sebrights. *Ducks* were first Aylesbury, second Rouen, and third Mallard. *Geese* were a good lot, the two first pens old White Embdens, and third a promising pen of Toulouse goslings. Mr. Snell won the point cup.

*Pigeons* had but few classes; first on the list were the Carriers, Blacks winning the prizes; the first a very good pair. Pouters, first White, and second Blue. Antwerps very good, the first Red Chequers, and second and third Silver Duns; first very good indeed. Fantails a moderate lot; but Owls grand, White African carrying off all the prizes. Dragons very good; first Yellow, second Silver, and third Blue. Tumblers, first Almonds, second Kites, and third Black Balts, all very good. The Variety class had nothing good with the exception of the three winners, first Silver Turbits, second Black Barbs, and third Black Jacobins.

*Cage Birds* were a failure; exhibitors will not pay 4s. per pen for a 10s. prize.

Mr. Yardley won the cup for points in Pigeons.

**POULTRY**.—*DORKINGS*.—1, W. Roe, jun. 2, H. Feast. 3, Miss M. Murray. *COCHINS*.—1, A. Darby. 2, H. Tomlinson. 3, H. Feast. *vhc*, Rev. R. Fielden. *BRAHMAS*.—1, J. F. Smith. 2, H. A. Barclay. 3, E. W. Snell. *HAMBURGHS*.—1, H. Feast. 2, S. B. Meynell. 3, E. W. Snell. *GAME*.—*Black and Brown-brasted Reds*.—1, H. E. Martin. 2, E. Winwood. 3, H. Butler. *Any other variety*.—1, H. E. Martin. 2 and 3, J. Calladine. *SPANISH*.—1, H. Feast. 2 and 3, J. Calladine. *BANTAMS*.—*Game, Black and Brown-brasted Reds*.—1, S. Beighton. 2, J. Mayo. 3, H. Butler. *vhc*, J. Osroff. H. Butler. *Any other variety*.—1, J. Osroff. 2 and 3, H. Butler. *vhc*, J. Mayo. *Any variety not Game*.—1, P. Foxwell. 2, H. Feast. 3, J. Calladine. *DUCKS*.—1 and 2, E. W. Snell. 3, H. JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

## DISEASES OF PIGEONS.

My experience does not lead me to accept your answer to "E. B. T.," in your number of August 17th, as correct. I admit that you can give a Pigeon what would kill a man, and that the dose will have no visible effect, but I deny that the internal diseases of Pigeons are incurable by medicine. I have had many cases of what your correspondent calls inflamed lungs, but which I should call bronchitis, and never seen one recover without treatment.

I have just cured two birds, a Russian Trumpeter and a Pouter. The symptoms were difficulty of breathing, a cough, and a rattle in the windpipe, with occasional coughing-up of mucus and loss of appetite. It is a form of roup, and attacks young birds when just commencing moulting, and sometimes old birds.

They are generally attacked very suddenly. They will take three weeks or a month of attention to get them over it, and of course may die in spite of all you can do for them. The treatment is:—Put them in a large airy pen free from draught, pluck the feathers from the throat and paint twice a-week with tincture of iodine. Give them a teaspoonful of Epsom salts in half a pint of water, and give no other water till they have finished it. Then give a capsule of cod-liver oil and half a Walton's roup pill every night, and cram with soaked beans, dipping one or two beans in each feed in sharp sand, if they will not feed themselves, and pluck-out all the tail feathers. I do not believe that the diseases of Pigeons are hereditary, for the simple reason that diseased birds do not breed.

I have had cases of wing disease and tumours in birds bred from perfectly healthy parents. Wing disease I look upon as incurable, but have been wonderfully successful in treating the same description of tumours on the legs and body with tincture of iodine. I must also deny that any amount of cleanliness or care will keep Pigeons free from disease whether confined or allowed to fly. I have never found homoeopathic treatment of any use. Your correspondent will find Fulton's chapters on diseases very useful. The Epsom salts for roup has the best effect, and will sometimes cure a bad case in two days. Never despair of a case of roup. I have a Trumpeter hen that last autumn had it badly for three months. However, she even-

tually by constant care and a great deal of physic recovered, won a second prize in January last, and has this season reared eight young birds.

I think the reason of many failures with sick Pigeons is want of perseverance, care, and cleanliness.—J. H. HUTCHINSON.

## NEW BOOK.

*How to Succeed in Poultry-keeping for Profit or Exhibition.*  
By G. W. BACON, 127, Strand, London, W.C.

We have before us this new book, and do not quite know what to say about it, for it seems to us in matter and illustrations merely a *rechauffé* of other works. In many ways it is harmless, and some two or three sections are useful and practical. The original parts give us the idea of having been written by some poultry-keeper who has rather looked upon birds with the eye for profitable table food than in the light of exhibition stock. There are plentiful quotations from the "Poultry Book for the Many" published at our office, from Mr. L. Wright's "Illustrated Book of Poultry," and from other sources, and these pieces are always acknowledged when copied verbatim. We wish the source of the illustrations had been as freely stated, for we can find no notice of their origin. It is palpable to many, however, that they come chiefly from the defunct periodical "The Poultry Review." Among them the best are Mr. Horace Lingwood's Dark Brahma cock, Mr. S. A. Dean's Light Brahma hen, the Rev. Reginald S. S. Woodgate's White Cochins hen, &c.; while the worst is undoubtedly the Buff Cochins cock, which might be of any colour, and the leg feathers are very unnatural. The chapters on "Food and Drink" and the "Rearing of Chickens," though they contain nothing new, are well put together, and contain many hints useful for young beginners; on the other hand, some of the advice offered is positively absurd. For instance, in the chapter on breeds it states, in reference to purchasing Cochins, "Do not select those with clean legs . . . nor with double combs." The youngest amateur surely knows that leg-feathering is one of the chief points of all Asiatic breeds. Mr. James Long is also quoted a good deal, and his classification of breeds is well put together. The breeds are so lightly touched upon that one page suffices for all particulars about Bantams, and it is in such points as these that we feel the work is wanting as a guide for new beginners—*e.g.*, in speaking of White Bantams we read, "neatness of comb" is a special point; but the comb may be double, single, pea, or falling over for all w; can glean from the work. Taking, however, the whole book into consideration we should call it a fairly useful little manual, but perfectly uncalled for in the midst of the cheap poultry literature of the present day.—W.

## THE STEWARTON SYSTEM AND THE STEWARTON HIVE.

THERE are many bee-keepers like myself who keep a few hives to supply their household and their friends with honey, but do not care to have a large number of stocks. They generally follow the non-swarming system, and prefer a moderate amount of super honey in the comb to any amount from a stock hive; but in spite of all their efforts their bees will swarm and increase their stocks beyond the required number, and at the end of the season give them just what they do not want—namely, the trouble of driving, uniting, and, worst of all, breaking up stock hives and running honey. In many cases no doubt the bees are condemned to the sulphur pit. My own system is to prevent my stocks from multiplying unduly by uniting a number of swarms. By this method I also get my deserted supers filled as well as others besides.

It is not everyone who cares to add swarm to swarm in the ordinary way of knocking them out in the evening and placing the hive to which they are to be added over them, with the trouble of placing all right early next morning. To these let me recommend the Stewarton system of adding swarm to swarm. It is simply to hive the swarm to be added to another in a hive or box constructed with bars, with moveable slides between the frames like the Stewarton hive; or, which will answer as well, a flat board or sheet of zinc, which can be withdrawn and placed over the bars. A cheese box perforated with a sufficient number of slits or fitted with bars would answer well for round hives.

The swarm is hived in this prepared box, placed as near as possible to that to which it is to be united, or merely left where it was hived till the evening, and at sunset placed gently beneath the hive to which it is to be united, and the slides or cover withdrawn, whereupon the new swarm will set up a pleasant hum, a sign that they are gladly joining their neighbours in the upper storey. The next morning the hive underneath may be removed, and the partially filled super deserted by the swarm placed on the top of the united stocks. A third swarm, if not too large, say a cast, may be added and additional room given above if the season be not too far advanced. One hive thus treated has given me two fine supers, one 15 lbs. and the other 12½ lbs. I have thus been led to think that for many

From observations taken near London during forty-three years, the average day temperature of the week is 71.0°; and its night temperature 47.2°.

## THE CULTURE OF ROSES IN POTS.

**R**oses are generally admitted to be the most beautiful flowering shrubs of our gardens, and for a number of years both in England and on the Continent they have occupied a large share of attention. Who is there that will come forward and deny that they have not a slight weakness, if I may term it so, for Roses? At all times Roses are strikingly beautiful, but more particularly so during spring and the early summer months, and

they are especially valuable for the ornamentation of the conservatory, and I know of no more pleasing sight than that of a house furnished with well-grown specimens bearing luxuriant foliage and well-formed flowers. So well do they harmonise and associate with other spring subjects that it is of their culture in pots for this purpose, as well as for exhibition, that I describe the method that I have adopted with a fair amount of success. Although, as Mr. Douglas in one of his excellent papers said, "it is not given to ordinary mortals to possess such plants as are annually exhibited by Mr. Charles Turner of Slough, and Messrs. Paul & Son of the Old Nurseries, Cheshunt," still creditable specimens may be grown by any enthusiast, even if only the convenience of a cold pit is afforded. I have grown and exhibited Roses for two years with no other convenience than a cold lean-to pit 20 feet by 8. I am not advocating this as the best place to grow them in, for it has many drawbacks compared with a house, but only to show that if no other means exist Roses can be grown in such a pit.

Perhaps never has there been a season when such encouragement has been offered for the cultivation of Roses in pots as during the spring and summer of this year, and never have plants, both large and small, been produced in greater perfection. The admirable collection exhibited by Messrs. Veitch & Sons at the Hyacinth Show at South Kensington in March last was an instance what an effect a collection of small plants will make early in the season. The extraordinary qualities of the flowers exhibited by Messrs. Lane of Berkhamstead at the Alexandra Palace early in May was another instance what may be done by healthy young plants grown in 8-inch pots; and the huge specimens 6 to 7 feet high and as many through shown by Messrs. Turner and Paul & Son at the two May Shows at the Westminster Aquarium, also at the Crystal Palace and the Royal Botanic, were marvellous examples of perfection in Rose culture, such quality of bloom and foliage being scarcely attainable out of doors. The Roses in 8-inch pots, also exhibited by these great champions, embracing all the new sorts of the last two or three years, must verify the fact that almost every Rose, whether Hybrid Perpetual, H. China, or Tea, does well under pot culture; and those who wish to procure a collection in the shortest space of time would do well to go to some nursery where this favourite is made a *specialité* and select as many plants from the subjoined list as means or convenience will admit. Now and during

September will be a very good time to select well-established plants in 6 or 8-inch pots, and such may be purchased at reasonable prices.

As soon as possible after receiving them from the nursery examine their roots, for it may be found that many of them will be benefited by a shift into 10-inch pots. This operation will also enable you to ascertain whether the drainage is in good order or not—a point that is most essential, for the Rose is very impatient of stagnant water at the roots. The following soil will be found suitable to them:—Good strong turfy loam the top spit from an old pasture three parts, the other part of well-decomposed cow manure, or sheep dung if it can be procured; a little leaf mould and a sprinkling of bone dust may be added with advantage. Chop and mix the compost well together and pot firmly, taking care that the plants are moist at the roots before potting them. After potting place the plants in a cold frame, admitting plenty of air by tilting the lights, and on all favourable occasions draw them entirely off. It is not warmth that is required, but a place of shelter from the heavy autumnal rains and very severe frosts. In these quarters the plants may remain until they are started into growth.

It takes, as a rule, from eight to eleven or twelve weeks to bring Roses in full bloom from the time they are started; and if wanted to bloom during May, which is the month in which pot Roses are usually exhibited, the first week in March will be found early enough to start them. Soon after the turn of the new year, say early in January, prune away all weak or watery-growing shoots, and shorten the points of all the shoots, more especially all such as are not well ripened; it is not, however, necessary to prune as hard as you would for a plant growing out of doors. Have a ball of cord or some other tying material in readiness for training the plants, begin by placing a string around the rim of each pot, then bring gently down the point of each shoot to the string; this to be continued until all the branches or twigs are bent back, so that they may be likened to an umbrella turned inside out. This severe training or bringing down of the branches is indispensable, as it regulates the sap and causes each shoot to break right back, which otherwise would not do so. By thus training a foundation is laid for good plants in future years, and the foliage of the plants is made to cover the rims of the pots. This operation must be done very gently, as too great a strain is apt to break the shoots; indeed I have known them to snap occasionally after being bent. It will not be out of place here to mention that some cultivators provide against bleeding by using a composition which is recommended in the "Gardeners' Year-Book;" its principal ingredients being pitch and fat. This is very desirable where Roses have to be started into growth soon after pruning them, and is an useful application.

If plants are not wanted to bloom until May they can be started about the first week in March in a cold pit or in a house set apart for them, and must be encouraged into growth by keeping them close and syringing them two or three times a-day with tepid water. If rain water

is not procurable, always place some pots of water in the sun to prevent that sediment which is so often found on the foliage of plants after using hard water. Keep the plants as near to the glass as possible, and close until the buds begin to burst strongly. As the buds begin to gain strength air must be given as weather permits. This simple work requires more than ordinary caution, as cold currents must be carefully avoided, and often during March we have strong bursts of sunshine with very keen cutting winds. The young and tender foliage is unable to bear these cold draughts, which are the cause, in my opinion, of the mildew. This past season was a very trying season for mildew. This pest must be kept in check by dusting with sulphur on its first appearance, or it will possibly spread all over the plants; so again I say, Carefully avoid all cold currents, and close early to husband the natural heat. In the morning you will be rewarded by finding the edges of the leaves covered with beads of dew, and the plants bearing a fresh and thriving appearance.

When growth has commenced the anxious grower will have to keep more than an ordinary look-out for that most hateful of all pests to the rosarian, the Rose maggot, which coils itself in the half-expanded leaves, and if not detected drills its way into the hearts of the flower buds, which have to be picked off; besides, the foliage will present a riddled and unsightly appearance. Wherever a curl appears there the enemy will be found lurking, and a simple pressure between the forefinger and thumb will soon settle him. Green fly will also be found to put in an appearance at this stage, and the syringe or a smoking or two with tobacco must be resorted to. I have invariably found as the plants gained strength that a good wash at times from a tolerably coarse-rose watering-can was more effectual than syringing.

As soon as the buds appear well above the foliage the plants should be trained into a somewhat flattened bush-like form, which form enables the grower to make a better display of his flowers, besides encouraging a more even habit of growth, taking care to distribute the flower buds regularly all over the plants. For this purpose neat sticks, such as small osiers used in the making of baskets, are suitable, choosing those that have been cut and laid by for some time, these being the most durable, and there is no fear of their taking root and growing in the pots. Place some of these sticks in a slanting position resting on the rim of the pot, and bring the lowest and most forward shoots down to the sticks, securing them neatly (the foliage from these when fully developed will completely cover the rim of the pot), carefully cutting away all the ties made when the plants were first pruned. Secure each of the growing shoots to the sticks, placing them equally over the plant until the desired shape is attained. This training requires both judgment, taste, and neatness; it also regulates or balances the sap throughout the whole plant, and the result is a number of blooms opening at the same time, which should be every exhibitor's aim, and which result could not be obtained were the plants allowed to take their course; the stronger shoots would outgrow and rob the weaker, and consequently bloom first. From the time the buds first appear manure water may be given freely, for when well established the Rose is able to absorb strong stimulants. Cow manure steeped in water in which a little soot is mixed is as good as anything. I have relied more on cow dung and soot this season than on any other manure. I have also successfully used a mixture of cow dung, horse dung, and sheep dung, a basketful of each to about a peck of soot, and a 6-inch potful of guano, the whole being put in a large tub and well stirred; when settled it is fit for use. If thought too strong dilute with water. My plants have always thriven well, carried rich foliage and well-formed flowers. I do not advocate a large quantity of guano; it will, in my opinion, produce large foliage to the detriment of ripe wood and less blooms the following season. Its properties are too heating for the Rose, whereas cow or sheep manure is of a cooling nature.

When the plants have done blooming and the weather has become warmer, say by the middle of May, plunge them out of doors in a bed of coal ashes or cocoa-nut fibre, cut off all dead flowers, and give copious supplies of manure water, or a mulching of rotten dung around them will answer the same purpose, for the watering and rains will wash its virtues in. It is on the summer growth that success mainly depends, and attention must therefore be given to produce it. Watering and frequent dampings overhead after a hot day will help to keep the plants fresh and healthy.

Most of the plants if they have made good growth will re-

quire a shift. This operation is best done from June to September—the earlier the better, as it gives a longer time for fresh roots being made, and the more a plant has filled its pot with roots the better will it be able to stand forcing and stimulants. If it is required to have flowers earlier in the season it will be necessary to prune the plants sooner than already stated, also to introduce them into a genial temperature of 45° or 50°, and if convenient a slight bottom heat of 10° more will materially assist. As the plants gain strength, if thought desirable they may be subjected to a temperature of 60°; but hard forcing should be avoided at all times, for it will be found detrimental to good blooms. The harder the plants are driven the smaller will be the flowers, as well as being devoid of colour.

There are other enemies to the Rose besides the Rose maggot, green fly, and mildew spoken of. The black mildew sometimes makes its appearance and sadly disfigures the foliage, causing some which is badly affected to drop off. For this I know no remedy; but for the orange fungus more air and less moisture will, I think, prevent its spreading.

At the commencement of this paper I suggested that the quickest method of procuring a collection is to purchase established plants in pots; but plants obtained as follows, although not fit for early blooming the first year, still may carry a fair supply of blooms and become thoroughly established the following year. The first step is to take up from the garden some dwarf Roses and put them into 6 or 8-inch pots, taking care to well drain them. Plunge the pots to the rim in a partly spent hotbed, and keep them close for a few days, giving one good soaking of clear water, and dew them over with a syringe on fine days, and in the course of a fortnight they can have air and be treated as for the established plants, only these require to be pruned hard back, and take a year or so longer in making good plants. If large quantities were treated in this way they could be plunged in an open space with sufficient cocoa-nut fibre to keep the frost from their roots and breaking the pots. They would then take care of themselves until the spring, and the rains would supply the same benefits as when planted in the open ground. They could be pruned in the ordinary routine of pruning outdoor Roses.

It is scarcely necessary for me to append a select list of Roses, as nearly all will answer well for cultivation in pots; but the following can be depended on, and each possesses some particular merit:—Anna Alexieff, H.P.; Annie Laxton, H.P.; Mad. La Baronne de Rothschild, H.P.; Beauty of Waltham, H.P.; Boule de Neige, H.P.; Countess of Oxford, H.P.; Duke of Edinburgh, H.P.; Edward Morren, H.P.; John Hopper, H.P.; La France, H.P.; Madame Lacharme, H.P.; Madame Thérèse Levet, H.P.; Madame Victor Verdier; Mdle. Eugénie Verdier, H.P.; Marguerite de St. Amand, H.P.; Marquise de Castellane, H.P.; Maréchal Vaillant, H.P.; Marquise de Mortemart, H.P.; Paul Neron, H.P.; Paul Verdier; Sénateur Vaisse, H.P.; Victor Verdier, H.P. Among the new H.P.'s that have been conspicuous at this season's pot Rose shows and which are worthy of cultivation are Capitaine Christy, John Stuart Mill, Rev. J. B. M. Camm, Star of Waltham, and Miss Hassard. These will make excellent pot plants.

All the Tea Roses are very effective in pots, but Alba Roses, Catherine Mermet, Cheshunt Hybrid, Madame de St. Joseph, Madame Willermoz, Niphotos, Perfection de Montplaisir, Souvenir d'un Ami, are the most reliable. Céline Forestier among Noisettes, Souvenir de Malmaison of the Bourbons, and Charles Lawson, Paul Ferras, and Juno of the Hybrid China section, are also sterling varieties for pots.

The best twelve are undoubtedly Céline Forestier, Madame Willermoz, Souvenir d'un Ami or Madame de St. Joseph, Cheshunt Hybrid, Alba Roses, Victor Verdier, Paul Verdier, Madame Victor Verdier, Madame Lacharme, La France, Duke of Edinburgh, and Beauty of Waltham. These all possess good foliage and well-formed flowers.

In conclusion, let me say to those who propose specimen-growing that they must have great patience and be exceedingly watchful, for a specimen pot Rose requires a great amount of attention to grow it in perfection, and many details must be attended to which cannot be well taught by writing.—J. W. MOORMAN.

#### CANADIAN WONDER KIDNEY BEAN.

In my opinion this is the finest Kidney Bean in cultivation. It is the only one I am growing this season, and I have made up my mind to adhere to it exclusively in future. It grows about 18 inches high. The pods are produced by the thousand

in long succession. Their average length is from 10 to 12 inches, and when cooked they are tender and delicious in flavour. We have gathered a good dish daily for the last five weeks from a few rows, which in all would make about 30 yards, and the supply is not exhausted yet. For market purposes it would be the Bean before all others. Half an acre of it would produce cartloads of pods.—N.

### LESSONS OF THE SEASONS.—No. 3.

#### SPRING.

WITH opening spring comes seed time, to meet and be in readiness for which much previous care and forethought is requisite. The treatment of garden borders and soil which is exposed to the action of the weather has already been explained; let us now go a step beyond this, and see what can be done for such crops as require some shelter and protection during the period of vegetation and the earlier stages of growth in the field, often severe, weather of spring. Early Horn Carrots, Radishes, Celery, Lettuce, and other salading; Cauliflower and Brussels Sprouts among vegetables, with such herbs as Sweet Basil and Marjoram, and the most delicate and tender annuals among flowers—these are the things to which I would point as being eminently worthy of our best care and attention. Some of the crops to be brought-on as early as may be for a kitchen supply, others to be in readiness for transplantation to beds and borders as soon as can be done with safety, so as to ensure strong growth and early flowers.

To obtain our end every available auxiliary—glass-light, hand-glass, and “protector” is brought into play, the best kind being that which is portable, suitable for its position, and offering no obstacle to the manipulation of the whole of the plants, which should be well within reach from every side. I am gradually accumulating a stock of very useful little span-roofed frames specially adapted to this purpose. They are 21 inches wide, 8 feet long, 1 foot high in the centre, and 5 inches high at the sides; each frame has only six squares of glass—three to each side, large panes of 24-oz. glass being found much better than small thin glass. The ridge bar projects about 4 inches at each end for handles to lift and carry the frame by. These frames, in addition to the important merit of cheapness, possess the advantage of thorough efficiency. They are light, yet very strong and durable; and although they are made of a suitable length to go across a certain border, they are also applicable to a variety of other useful purposes.

To render one quite independent of the weather—or rather to enable one to make use of the frames at any time—there must be a supply of rich sweet soil kept ready at all times for sowing or planting in, precisely such as is used for potting such free-growing plants as *Fuchsias* in—moist yet not wet, so that when handled it crumbles to pieces freely. For this purpose there should be a soil lodge in every garden, of a proportionate size to the requirements of the establishment, an annual supply being stored therein just about the present time, before the autumnal rains set in. The primary object in the building and storing with soil of such a lodge is to have a sure supply for pot plants, a matter of the utmost importance at all seasons of the year, but especially so in spring, when propagation and repotting come pressing upon us with such rapidity as to make the slightest hindrance a serious matter, not unlikely to have an evil effect upon the results of an entire year. Preference is usually given to a building closed on three sides, but with that which is least exposed to rough weather left open, so as to have the soil constantly subject to the sweetening influence of fresh air. Not many kinds of soil are required. Our first heap should be of light sweet turfy loam; next comes a stack of light upland fibrous peat, then another of very old black-looking manure, then leaf soil as old as we can procure it, with a substantial heap of white sharp gritty sand; charcoal, finely shattered brick, sphagnum, and broken crocks being kept in the potting shed.—EDWARD LUCKHURST.

### ROYAL ASCOT PEACH.

WE have received from Mr. Speed of the gardens, Chatsworth, fruit of the Royal Ascot Peach, with the following communication:—

I send you fruit of the Royal Ascot Peach to give you some idea of its lateness. We commenced gathering Prince Albert Nectarine, which, by-the-by, is the earliest Nectarine I know, on the 26th of June, and Elruge, *Violette Hâtive*, &c., the first week in July, and we are now gathering the Royal Ascot Peach.

The fruit I have sent you is rather smaller than usual, owing to a very heavy crop. It is a good setter, and has a strong constitution. The flowers are large, and I have enclosed you leaves that you may see the glands. Planted in a late house it would doubtless be later than any other Peach and much better quality than such as Walburton Admirable, Salway, or Barrington.

### WATERING.

IN dry seasons like the present there is always a great deal said and written in the horticultural journals about watering, and I am inclined to think that more than half of it is nonsense. “Peas should have abundance of water, fruit trees should have abundance of water, French Beans ditto,” and so on all through the kitchen garden, flower garden, and orchard. Now, it is quite certain that three parts of the people to whom such advice is given have not the slightest idea of what an abundance of water to a thirsty plant is, and I cannot imagine that the practical experience of the writers of such articles can be quite perfect, or they would be a little more careful in giving their advice. I do not hesitate to say that there is more harm done by watering as frequently practised in the present day in the case of outdoor plants not in pots than there is good. It is utterly impossible, if it were necessary, to apply water in sufficient quantity to do any good to all the plants to which we are recommended to apply it in such a season as the present, and I will attempt to show that it is frequently unnecessary to apply it at all.

First, let us think what is a sufficient quantity of water to apply to thirsty ground when it becomes absolutely necessary to apply it. It is of no use to measure the rainfall of a district for this, for water as applied from the clouds is very different to artificial application. When it rains there is little or no evaporation going on, but when we water outdoor plants artificially the evaporation is often so great that the atmosphere takes up the greater part of the water without its entering the plants at all. Then there is the thirsty ground adjoining that for which the water was intended, which often takes a great deal, so that probably only a very small proportion enters the system of the plants; and just imagine the amount of leaf-surface of a good-sized tree (it certainly would not take a very large one to have a quarter of an acre of evaporating surface), exposed to an atmosphere nearly as thirsty as a red-hot brick.

In our houses we have the atmosphere partly under control, and after some years of experience we find out the quantity of water necessary for any given indoor fruit border, so that we can tell unskilled men, if we can only trust to their honesty, exactly how much water to apply. The borders of my principal vineries may be taken as an example. They are heavier than Vine borders usually are, being composed of nothing but loam and a few half-inch bones, and are nearly 3 feet deep, consequently they do not require so much water as they would if shallow and more porous; but for all that the quantity I consider necessary for one application is about forty gallons to the square yard as far as the roots extend. This lasts them about three weeks, or sometimes a month, according to the state of the outside atmosphere. This be it remembered is indoors, in one of the most perfect houses it has been my lot to see, where we have to a considerable extent control over the atmosphere; and if this quantity is necessary there, I maintain that a fourth of the quantity applied to soil full of the roots of a tree outdoors is worse than useless, unless means are taken to prevent it going off rapidly into the atmosphere. Many vegetables and flowering plants, of course, do not root so deeply, and therefore do not require so large a proportion of water at one time; but it is not often that these are given a sufficiency, and I should not have to travel far to find instances of plants killed this season by watering, which would have survived if no water had been applied.

How deep is the prejudice against watering Peas and some other kitchen-garden crops amongst workmen! What kitchen-garden labourer cannot tell of crops spoiled by watering? Such deep-rooted and wide-spread prejudices are seldom without some reason, and the reason for this one is that nobody waters half sufficiently when they do water, and thereby do a great deal more harm than good.

Deep-rooting crops should not be watered so soon as the surface becomes dry. A dry surface if kept loose is very effective in retaining moisture below, and to wet that surface for 2 or 3 inches down, as is often done with the water-pot, is to

unlock the earth and conduct into the thirsty air the precious stores from the rootlets of the plants.

The soil below the surface should always be examined when practicable before watering, and when water is absolutely required no half measures should be taken. A covering of some dry material after watering is of great service—dry loose soil, dry litter, or in fact anything which will lie loose and enclose a large volume of dry air, will to a great extent prevent the water applied rising into the air and the sun heat penetrating too much to the roots of the plants, thereby diminishing considerably the need for the water-pot. Soils resting on clay, and perhaps some others if covered in this way, will keep sufficiently moist through the driest seasons without any artificial watering.

Outdoor plants will often flag because the atmosphere is dry. There is no help for this, for we cannot water the atmosphere sufficiently, and damping the tops of the plants under such conditions will only do them harm.—WM. TAYLOR.

## 1 S IN THE ROYAL GARDENS, KEW.

ON the Rockwork is a new and interesting hybrid Campanula, one of the many productions of Isaac Anderson-Henry, Esq. This is *C. Haylodgensis*, obtained from *C. pusilla* alba and *C. isophylla* alba, two very distinct species. Their offspring is quite intermediate in point of form and habit, though, being blue, is like neither in colour. The new hybrid will prove a useful rockwork plant on account of its free-flowering qualities, and also because of its neat and distinct appearance. *Oxalis enneaphylla*, though not now in flower, claims a brief mention. It is one of the most interesting of this once-popular genus, and though not decidedly showy is yet very attractive, chiefly on account of its silvery leaves and large white flowers. The leaves are peculiar from having from five to twenty leaflets, though in cultivated plants they are usually about eight or ten. It is a native of the Falkland Islands, and was introduced by the Challenger expedition. *Gladiolus purpureo-auratus*, a showy and handsome species, is remarkable for its golden-yellow flowers. There are purple spots, however, on the two lower segments. It was introduced from Natal by Mr. W. Bull. *Rhexia virginica*, though not new, is extremely rare. It has pretty pink flowers, and is the only hardy Melastomaceae plant we have in cultivation. It was figured on page 4 of the current volume of the *Journal of Horticulture*.

A very fine plant of *Fourcroya gigantea* is throwing up a flower stem in the Succulent house. To be correct, however, it is not altogether in the house, but about 4 feet of the stem is above the roof outside, and is still growing fast. *Sarcostemma Brunonianum*, an interesting Asclepiad, is in flower near the north door. It has long, green, cord-like, pendulous stems, along which clusters of pale greenish flowers are produced at intervals. It grows in Ceylon, and is also common in arid jungles of the Madras Presidency, "where it forms great masses, climbing over shrubs, tree trunks, and stones, abounding in an acid milky juice, and hence eaten by the natives as a salad and sucked by travellers to allay thirst, thus forming a remarkable exception to the usually poisonous nature of the Asclepiadeous juices."—*Botanical Magazine*. The very remarkable Cactus, *Leuchtenbergia principis*, which bears its flowers on the summit of the mammæ, will shortly be in bloom.

Of the finer Orchids now in flower, *Eulophia guineensis* is the least known and most rare. It has several times had eulogistic notice in the gardening papers. The flower spikes are about 2 feet in height, producing numerous flowers of large size. The sepals and petals are narrow, ascending at right angles to the labellum, which is nearly round and of a beautiful pinkish colour. *Dendrobium Pierardi* appears continually in flower; others flowering at the present time are *D. aduncum*, *D. Bensoniæ*, and *D. sanguinolentum*. Several plants of *Cattleya crispata* are in bloom. *Calogyne speciosa*, a grotesque brown flower, is strange in contrast with *C. ochracea*, a very pretty white and yellow kind, which we have before described. *Thunia alba* has been very attractive for some time; it is one of the few Orchids having a graceful habit. *Disa grandiflora* is just now very ornamental. Other cool Orchids in flower are *Odontoglossum crispum*, *Miltonia spectabilis*, and *M. Regnelli*, a very pretty and distinct kind, said to be rare.

In the Begonia house we find *Liebigia speciosa*, a plant not only of great beauty but also of much interest on account of the distinguished chemist whose name it bears. It was imported from Java by the Messrs. Veitch through their well-

known collector Mr. Thomas Lobb, and was figured in 1847 in the "Botanical Magazine," though probably it has been lost to the country for several years. The stems are soft and green; leaves opposite, light green, ovate or elliptical, and covered with rigid hairs. The flower stems are in axillary panicles, few or many-flowered. The flowers are tubular, somewhat Gloxinia-shaped, but rather smaller; the corolla is white, with the tube violet-purple on one side.

In the next house is a fine new Begonia of the tuberous-rooted section, *B. Froebellii*, introduced from the Republic of Ecuador. It is quite distinct in habit. The leaves are all radical, with stems 6 or 8 inches long: the blade is obliquely cordate acuminate, and is covered with hairs on both surfaces. A peculiarity of the flower stems is that they are either male or female, only one sex being produced on a scape. The flowers are about eight on each stalk, and rise rather above the leaves. They are not quite so large as in most of the allied kinds, but are of an intensely rich crimson colour.

## A VISIT TO THE SOUTHWELL NURSERIES.

THE nurseries of Mr. H. Merryweather of Southwell possess many attractions, not only to the rosarian, but also to the general florist and horticulturist, for here, besides thousands of Roses raised annually, there are all the leading sorts of fruit trees, a fine collection of Conifers and evergreen shrubs, forest trees, herbaceous plants, bedding plants, a fine assortment of Ferns, Camellias, Azaleas, and other greenhouse plants, all cultivated with energy and skill, and all kept in a clean and healthy condition.

However, the most attractive feature at Southwell during the month of July was the Roses, and it was these that I specially went to see. I had the privilege, in company with Mr. H. Merryweather, jun., of noting all the valuable Roses both new and old. Captain Christy, a delicate rose, quite new in colour, was in superb condition; it is a fine addition to the light Roses. Mdle. Marie Cointet is one of the most perfect Camellia-shaped Roses in cultivation; light satin rose, and a favourite with everybody. Louis Van Houtte, a better Rose does not exist; it is grand dark Rose, one of the best of its colour; a fitting Rose for such an honourable name. Xavier Olibo is another grand dark Rose which should be in every collection; it was here in splendid condition. Horace Vernet was quite equal to the last. Madame Victor Verrier is a dark Rose of the Sénateur Vaisse type; it is a brilliant rosy crimson, and so good that too much cannot be said in its praise. Marie Baumann was in foliage, shape, perfume, and colour all that could be desired; it was simply perfection. Dr. Andry was splendid; it is a gem of the first water—a perfect Rose. Mdle. Bonnaire, most delicate blush; the finest Rose that can be found for ladies' bouquets. Pauline Talabot, a dark shade of rosy carmine; promises to be one of the best new Roses of 1874. Pierre Notting, here we meet with an old friend in no way impaired by his age; grand in all respects. Duke of Edinburgh, very fine. Madame Boutin, a beautiful clear Rose, still blooming in grand form; one to be desired. Duchess of Edinburgh was thin in petal and wanting in the general character of a good Rose. Marguerite de St. Amand, beautiful light satin rose, was very lovely, possessing all good properties; it is alike good on the exhibition stand and in the garden. Marquise de Castellane; this—on the Briar, Manetti, or on its own roots—is always alike good. Maréchal Vaillant, very full, with a flaming centre and fine foliage. Dupuy-Jamain, bright cerise crimson, with a suffusion of violet; a remarkable Rose. La France, so prolific and profuse in bloom that it is the one for a single bed, and should be grown in quantity in every garden. Thomas Mills, so bright is the colour of this Rose that it may almost be termed a scarlet; very large, full, and will become a great favourite. Mdle. Marie Rady, a most perfect gem; fine shape and form. Alfred Colomb, one of the grandest of all grand Roses; this and Marie Baumann should be in every collection. Boule de Neige, very useful as a garden Rose for cut blooms. Abel Grand, a well-formed and good Rose; not so large as many others. Louise Peyronny, this beautiful Rose sustains its character for the exhibition tent; it was exceedingly fine. Hippolyte Flandrin, a Rose of high quality, but neglected; however, it will come to the front again. Madame Hippolyte Jamain, fine foliage; one of the best. Sir Garnet Wolseley, a fine crimson rose, of the character of Exposition de Brie. Crimson Bedder, a new Rose, useful for the purpose that its name indicates. Mdle. Marguerite Dombrain—what a pity that this beautiful Rose should be of such delicate

habit; it is one of the most beautiful pink Roses in cultivation, very large and full, and the shape perfect. Auguste Neumann, a full-sized, perfectly-formed, dark crimson Rose, the flowers being very erect. Princess Mary of Cambridge, fine silvery pink; a desirable garden Rose, but not quite large enough for exhibition purposes. Mdle. Eugénie Verdier; in this we have a distinct shade of salmon pink of the Victor Verdier type; a good Rose. Charles Lefebvre; dear old Charles! what a true friend, always alike good. This is the poor man's Rose, the rich man's Rose, and everybody's Rose, so good that it needs no praise; and almost equally good is *Sénéateur Vaisse*.

Of the newer Roses Etienne Levet was a marvel of beauty, the best Rose sent out in 1871; for substance of petal, colour, foliage, and shape without an equal. Miss Hassard, beautiful soft pink, recurved petals, very full, of perfect shape, erect in habit, with fine foliage; unquestionably one of the best English Roses in commerce. Mrs. Baker, a darker shade of Victor Verdier, and a promising flower. Rev. J. B. M. Camm, bright rose, globular, very full, very much in the style of the Marquis of Castellane; a fine exhibition Rose, supposed to be the sweetest Rose in cultivation. Royal Standard, globular, rosy pink, after the style of Emilie Hausburg; a promising Rose. Miller Hayes, scarlet crimson, deepening towards the centre; a very fine Rose. W. Wilson Saunders, intense scarlet, a superb Rose, but scarcely large enough for the exhibition stand. Comtesse de Serenyi, fine recurved petals, delicate blush, deepening towards the centre; a Rose of perfect form, and a fine addition to the light colours. Villaret de Joyeuse, bright rose deepening towards the centre; a promising variety. Reynolds Hole, a very dark rich crimson maroon flushed with scarlet; this Rose is improving, and will become like its namesake a universal favourite. Madame la Baronne de Rothschild, a splendid Rose, too well known to need comment. Madame Marie Finger, a glorious Rose for cut blooms; salmon pink, somewhat deeper than Eugénie Verdier. Alice Dureau, a fine Rose of the Comte de Nanteuil type. Anna Laxton, an improving variety, beautiful bright rose, fine foliage, and well-arranged flowers. Antoine Mouton, a brighter shade of Paul Neron; young blooms are very pretty, but you must not see it open. Auguste Rigotard, glowing rosy crimson with a beautiful violet suffusion; a grand flower. Black Prince, dark crimson shaded black; occasional blooms are marvels of beauty, but I am told they are "like angels' visits, few and far between." Cheshunt Hybrid, bright carmine; the young buds are all that can be wished for; a valuable Rose to mix with cut flowers, and a fine companion for Gloire de Dijon as a pillar Rose. Countess of Oxford, this is a noble flower with splendid foliage. Camille Bernardin, bright red; a flower of first-class quality, very free. Duke of Wellington, fiery red with dark shadings; extra fine. Ferdinand de Lesseps, purple shaded violet, splendid foliage, very fine. François Michelin, beautiful bright Rose of high quality. Frederick Wood, a promising dark crimson Rose. Lord Macaulay, bright crimson; a Rose of a most striking colour, and not sufficiently planted. Madame Clémence Joigneux, bright rose, rough at times, but here I found it in excellent condition. Madame Fillion, particularly distinct in colour, salmon pink; a very desirable Rose. Madame Louis Levêque, beautiful clear rose, very full and globular. Madame Lacharme, in this beautiful Rose we have the queen of whites; nothing can equal it in bud, and what can equal its pearly whiteness when in bloom? Monsieur Noman; the fresh blooms of this Rose are charming, but are quickly damaged by rain.

The above ends my notes on the Hybrid Perpetual Roses, and I only noted two of the Bourbons—Baron Gonella and Souvenir de la Malmaison. The former is a bright cerise with bronzy shadings, very distinct; and the latter is one of the oldest favourites in the garden; no collection is complete without it, especially for autumn blooms.

Of the Tea-scented Roses the following were the best:—Anna Olivier, a full good Rose. Aline Sisley, deep purple rose, very distinct and useful, good for forcing. Belle Lyonnaise, a very attractive variety of Gloire de Dijon; a most desirable Rose. Catherine Mermet; this beautiful Rose almost surpasses in beauty anything I have met with in the Tea Roses; shape perfect, colour beautiful soft salmon rose. La Boule d'Or, golden yellow; it is useless attempting to describe this "beauty," it is a perfect gem. Louise de Savoie, not a new yellow Rose, but very fine. Madame Jules Margottin, very much like a small Devoniensis with a pink centre; fine for cut buds. Madame Marie Van Houtte; here is another

charming Rose, very light yellow with soft rosy shading. Madame Willermoz, waxy petals; a most beautiful Rose. Madame Caroline Kuster, than which no Rose is more perfect for cut flowers. Marie Guillot, very full, a good addition to the Tea Roses. Niphetos, strikingly beautiful when the buds are half open. Perle des Jardins, one of the finest yellow Roses in commerce. Souvenir d'un Ami, a superb Rose of the very highest order. Souvenir d'Elise, creamy white, large waxy petals of great substance; very fine.

The Moss Roses were all over with the exception of one, Souper et Notting. There were rows of this covered with a profusion of bloom as sweet as any Moss Rose, and very good.

Maréchal Niel I met with in all stages and forms—in pots, on seedling Briars, low standards, and full standards. In one house there is one of the largest trees in the kingdom, from which was cut one morning 1500 blooms; but although it has a stem as thick as an ordinary man's leg, it is now swelling out of the stock and will soon have to be destroyed. Tea Roses are here extensively grown in pots; one house was filled with a fine selection of healthy plants in vigorous health, and many were plunged in coal ashes out of doors.

Speaking of the new Roses of 1875, after a very careful selection I think the following will be among the best French varieties:—Antoine Mouton, Comtesse de Serenyi, Frederick Wood, Hippolyte Jamain, Mons. E. Y. Teas, and Villaret de Joyeuse. The following half dozen are among the best English introductions:—John S. Mill, Miss Hassard, Rev. J. B. M. Camm, Royal Standard, Sir Garnet Wolseley, and Star of Waltham. I am glad to find we are likely to have further additions from our English raisers, which is much to be desired. The following are very promising:—Dr. Hogg, Mrs. Baker, Oxonian, Sultan of Zanzibar, Duke of Connaught, Letty Coles. French sorts, which are also good, are Duchesse de Vallombrosa, Henry Bennett, Jean Liabaud, Madame F. Jamain, Mdle. Emilie Verdier, President, Leon de St. Jean, and Triomphe de France.

But these nurseries are not entirely confined to the rearing and growing of Roses. There is a general stock of shrubby and ornamental trees carefully cultivated. I noticed fine quarters of *Wellingtonia gigantea*, and groups of *Cryptomeria elegans* were growing as freely as the common Larch. *Rhus glabra laciniata* was so beautifully cut in its foliage that it might be taken for a Tree Fern. *Acer Negundo variegata* appeared to be growing in great luxuriance, and I may say that we have no hardy variegated plant equal to it. Of variegated and plain-leaved Ivies there was a large stock in fine condition. Clematises I found growing in various forms, but those pegged-down in the flower garden were specially beautiful. To name the best of them would only be telling an oft-repeated tale.

Herbaceous and alpine plants also find here a congenial home. There were Phloxes and Pentstemons in great profusion. *Anubrieta purpurea variegata* was largely represented; it is a gem for the spring garden. *Plumbago Larpentæ* had stood out all the winter, and was in full bloom; but the most attractive of perennial plants was *Anemone japonica alba*, a plant with luxuriant dark green foliage, and a profusion of flowers as white as snow.

In concluding these notes it is only just to say that every part of the nursery was in perfect order, the fruit trees healthy, and the plants in the houses were in good condition and free from insects. This is one of our most promising midland nurseries, and in the Rose season affords an admirable opportunity for forming an estimate of the varieties, for all the new and most of the old Roses are well and largely cultivated, Mr. Merryweather, jun., being an ardent rosarian.—Q. R.

FERN LIFE IN DEVONSHIRE.—"The railway—to the lover of nature—mars the free wild aspect of the woods and fields. But Nature conquers everywhere in Devonshire. Even its iron-lined roads are subdued by the softening influence of plants and shrubs. The Ferns, especially, resent the intrusion of the railway engineers. Dry, hard, bare cuttings may be made through the hills; the turf, Heather, and wild Bracken may be stripped off along the valleys; the lines may be laid down, and everything done to make the scene look as commercial and uninteresting as possible. But the spontaneous influences which produce vegetable life will overcome all this. The rain comes down, and on to the softened earth the grass seeds blow. Thistle and Dandelion will send their germs in light and airy chariots; and Fern spores in countless numbers will find their way where the navvy has ruthlessly stripped off the verdant carpeting to make room for the iron roads. Nature,

indeed, everywhere more or less asserts her sway, and clothes our roads and railways with her charming dress; but it is especially the Ferns with which roads and railways have to contend in the charming county of Devon—the Ferns which carry everywhere a soft and indescribable grace.”—(*The Fern Paradise*, by Francis George Heath.)

### INJURIES BY HAILSTORM.

THE destructive storm that occurred on the night of July 23 wrought such havoc in the district of Tottenham, Stoke Newington, and Hornsey that a considerable amount of personal suffering as well as loss is the result. Those who have suffered most severely are the nurserymen and gardeners, glass houses being wrecked and standing crops crushed. In the interest of the nurserymen and gardeners a subscription has been started by a Committee formed for the purpose, but this subscription progresses so slowly that it becomes necessary to make an appeal to the public. It happens that in the locality where the destruction principally prevailed those who most truly sympathise with the sufferers are themselves losers to such an extent that they cannot do as they would in aid of their poorer neighbours.

It is proposed to raise £4000 at the least, and apportion it in accordance with the recommendation of a survey committee of practical horticulturists who have had experience in the valuation of nursery stock and other outdoor properties. Towards this amount about £500 have been already subscribed, the Baroness Burdett Coutts having generously given £50, while the principal nurserymen have contributed liberally. In a majority of cases where help is needed speedy aid is most important, for in many instances the trade stock for 1877 must be secured before the present summer wanes. Those of your readers who wish to respond to this appeal may forward their subscriptions to the Treasurer, Mr. Shirley Hibberd, Bridge House, Stoke Newington; to any of the branches of the London and County Bank; or to—JOHN FRASER, *Chairman of the Committee, The Nurseries, Lea Bridge Road, Leyton, E.*

### EARLY APPLES.

DURING all seasons early Apples are coveted, but especially during a season like the present are these crisp, juicy, and delicious fruits appreciated. The dearer an article is the more it is valued, and as early Apples have this season been sold at a penny each, that fact is sufficient to render a supply of them desirable. But apart from their scarcity early Apples may be estimated on their merits. They add to the dessert a total change from the soft fruits of early summer. Strawberries, delicious while they last, eventually pall on the palate, and the same in a degree may be said of Raspberries, Currants, and even Gooseberries; whilst Grapes, that princely fruit of almost perennial virtues, cannot wholly satisfy the cravings for fruit, but something more substantial is desired—something crisply sweet and pleasantly brisk, and these qualities are almost exclusively combined in Apples.

It is a remarkable fact that in many gardens where such fruits as Peaches, Nectarines, Apricots, and even Grapes are produced in abundance, the supply of early Apples is quite inadequate to the demand for them. Apples there are which ripen late in the season, but during July, August, and September—the very time when Apples are appreciated—they too often are hanging green and sour on the trees. Even when extensive collections of Apples have been planted only about one tree, or one tree of a sort of one or two of the earliest kinds, have been included, and these, especially in seasons of light crops like the present, have been quite insufficient to produce the desired supply of fruit. In all gardens having to supply families of a considerable size not less than two or more trees of a sort should be planted of the standard kinds of early Apples. Even if the trees at times produce more fruit than is required for the dessert no great fault has been committed, for nearly all early Apples are delicious when cooked, and some of the sorts are free bearers and profitable.

Some of the earliest dessert Apples are rather shy bearers, and on that account, perhaps, they have not been so freely planted as they would have been were they productive. But irrespective of their bearing properties, their earliness and refreshing qualities should ensure them a place in most gardens; and their shyness, so far from acting as a deterrent, should act the other way, and, instead of one, three or more trees should be planted to insure a supply of dessert fruit. I am intimately

acquainted with a nobleman's garden which contained three old trees of the Joanneting which during most years produced a fair sprinkling of fruit, and which was always appreciated. These trees were, however, in the estimation of the gardener inconveniently placed, and after frequent applications made for their removal the owner at last reluctantly gave his consent, a consent which he ever regretted, so greatly did the family miss the crispness and vinous flavour of their favourite summer Apples. This is probably the earliest Apple of the year, and when gathered off the tree it is most refreshing, but it does not keep long, nor is it required to do so when there are other good sorts which immediately follow. It should be grown because of its earliness and desirable table qualities. This kind has many names, as Juneating, Golden Beauty, Ginetting, &c., and unfortunately more than one kind is cultivated under the same name. The true Joanneting is a small

Fig. 21.—Joanneting.

Apple, round and slightly conical, smooth, and of a bright yellow on the sun side, and occasionally tinged with red; on the shaded side it is greenish yellow. The tree is a good grower, and also bears fairly well when grown on the Paradise stock. It is a very old Apple, and from the fact of its having ripened occasionally at the end of June when grown on a wall its name of “Juneating” is by some said to have been derived. Dr. Hogg, however, in his “Fruit Manual” does not believe this to be the correct derivation, and clearly traces the name from Joannina, an Apple ripening about St. John's day, which is undoubtedly, the period of ripening of this favourite Apple. I submit a section of a fair example of the Joanneting, showing its true form. I recommend this Apple as worthy of being grown by all who do not possess it, and as an Apple that is sure to be appreciated during the sultry period of its ripening.

Another valuable early Apple which is by no means commonly cultivated is the Summer Golden Pippin. I have found

Fig. 22.—Summer Golden Pippin.

this to be of the greatest value by its earliness, firm juicy flesh, and sparkling flavour. It is considerably larger than the Joanneting, and the tree is a good bearer. It is dwarf grower, and is well suited for the bush form of culture. When grafted on the Paradise stock it commences bearing when in

quite a small state. The skin is covered with russet dots, and is streaked with brownish red next the sun, the shaded side being pale yellow and shining. It is in use at the present time, and is much prized by the family. This is called the "White Pippin" in some districts, but why I cannot imagine, for its flesh as well as its skin is yellow. I have grown it both on the Crab and Paradise stocks, and it is best in quality from the latter, but the tree is a pigmy, and shows signs of canker. I am afraid—indeed I am certain—that the true kind is not always cultivated under this name. The Apple from which the accompanying sketch was taken was, I believe, a fruit of the true variety.

I have mentioned the above Apples, the one for its earliness, and the other for its good qualities and as not being extensively cultivated, and I now mention a very old favourite, one of the most profitable and valuable Apples that can be grown—the Devonshire Quarrenden. It is now ripe and will continue

Fig. 23.—Devonshire Quarrenden.

throughout the month. Whether we regard this Apple for its beautiful appearance, its refreshing juiciness, its hardness and great bearing properties, we must pronounce it the king of early Apples, and no garden or orchard can be considered complete which does not contain trees of this excellent variety. It is admirably adapted for orchard cultivation, and will grow in any soil in which other kinds will flourish. It forms a handsome head as a standard tree, and in all favourable seasons its branches are wreathed with crimson fruit—crimson where exposed to the light, but light green where shaded by a leaf, causing the fruit to have a beautiful dappled appearance.

It is one of the best of Apples for home use and for market purposes, and during the present month the supply of it in all the principal markets will exceed that of any other Apple, a circumstance speaking highly of its productiveness and value. And yet this deservedly popular Apple is not grown everywhere, for there are many gardens which do not contain it, and in my district I can say that friends will come and send from long distances to beg, buy, or borrow dishes of my covetable "red-cheeked" Apples. The figure is of a section of a medium-sized ripe fruit, and is certainly the most handsome Apple that I can now send to table.

It is because I have found the Apples named extremely useful and much valued, and because I do not find them by any means in all the gardens which I visit, that I draw attention to them at a time when their qualities are fresh in my memory, and when the period for planting fruit trees is fast approaching.—A NORTHERN GARDENER.

### ROSES FOR TOWN GARDENS.

A CORRESPONDENT, Mr. W. Symon, having sought for information about growing Roses in the vicinity of towns, we publish the following excellent advice on the cultivation of Roses, with well-selected list of varieties, which cannot fail to be useful to those endeavouring to grow Roses in small villa gardens in the vicinity of large towns.

"The smoke of large towns is no doubt injurious to the growth of Roses. Standards do not do so well as dwarf bushes near towns. Choose the strongest growers with the best foliage. I give a list of eighteen or twenty varieties which are likely to do best. Have them budded on the Manetti, and

plant deeply—that is, bury the junction of the scion with the stock at least 3 inches below the level of the soil. Mulch the ground during the autumn and winter till about the first week in April with good stable manure, then take it off, fork the beds gently over, and keep the hoe going through the summer. If the leaves turn black or mildew attacks them give liquid manure—guano and superphosphate dissolved in water about 2 ozs. of each to the gallon; and if much troubled with smoke syringe the leaves with water containing a little soft soap in it, about an ounce to three gallons, following it up before the plants are quite dry with pure water—soft water if obtainable. The leaves sent are suffering from black mildew and a little orange fungus, chiefly caused by the exceeding dryness of the summer.

The best sorts are Alfred Colomb, John Hopper, Fisher Holmes, Mad. Clémence Joigneaux, Gloire de Dijon, Maréchal Vaillant, Marquise de Castellane, Dupuy-Jamain, Mdle. Marie Rady, Abel Grand, Marguerite de St. Amand, Annie Wood, Boule de Neige, Baroness de Rothschild, La France, Princess Mary of Cambridge, Général Jacqueminot, Jules Margottin, Edouard Morren, Etienne Levet, and François Michelin.

In all gardens exposed to the east and north-west winds prune late. Thin out all old and all weak wood, and cut all strong young wood back to four or five eyes. Always try and encourage young wood to be made from the base. Do not mind the plants looking short and small when you have done pruning in April. If the soil has been properly treated in winter you will soon have plenty of growth when warm weather sets in.

Many Roses in small gardens are spoilt by constant dribblings from a water-pot, and others from fear of cutting away too much wood, or from close planting and allowing other plants to crowd them. A golden rule is to give plenty of space; Roses like air, but not wind, and in exposed places should be staked, and protected, which can be done very often by planting bushes, as Yews or Box, on the windward side, care being taken not to let the shrubs interfere with the Roses."—C. P. PEACH.

### GARDENING IN THE OLD WORLD AND THE NEW.

Your Journal reaches even to the "far west," and is welcomed not only as a recorder of progress in the "old country," but as affording much information that is useful even in the "new world." We are here a severely practical people, and ever are on the look-out for that which is useful. The luxuries of eastern life have not yet overtaken us, but we are well in the van of civilisation, and can appreciate a dish served tastefully, provided it contains something substantial. We do not "go in" for table decorations and "colouration," simply for the purpose of making a display, and I am not certain that the "old folks at home" are so ardent in these matters as they used to be—at any rate, when I was lately on the "other side of the water"—i.e., in London, England, I heard sundry allusions to the frothiness, flimsiness, showiness, and change-fulsness of the habits of society. And as we have a saying here that "when a man knows he is a fool there is some hope of him;" so when a fact is realised, and padding and gilded make-ups are recognised, it is a sign that mere glitter is not satisfying, and that the common remark one hears of this or that being "overdone" is a little significant.

When in London I heard on all sides that showing had been "overdone," and that shows did not "take;" that bedding had been "overdone," and there was an inquiry for "old-fashioned" plants; that awarding prizes was being "overdone," and the honours were not properly honoured by the public; that the naming of plants and vegetables was being "overdone," that new names were sometimes given to old articles, and those which were new were not always better than the old; that there was an increasing number of "superbissimas" and "splendidissimas," and such-like grandiloquent superfluities attached to very plain subjects. All that and much more I heard when in the old country. I heard, for instance, that the "new race of gardeners" might "talk finer," but they did not "do better" than the "old standards," the "plain old sticks," who covered our walls with fruit trees—such trees that the "young school" say they have "not time to train;" who planted our orchards, those old plantations of fruitful trees of useful fruits which are yet relied on for the "market supply;" who planted Vines half a century ago, and which yet produce luscious clusters of Grapes; who had great

field days of Pinks and Carnations, Hollyhocks and Dahlias Auriculas and Polyanthus, which the "young 'uns" cannot equal—times of floral refreshing which gladdened many a heart—times of sober joy to those belonging to the "steady plodding school," but which have no reflex in these modern days; but yet even now when the "tide seems to be turning" there are a few left who believe in the "good time coming," when real florists can again meet in congenial conclave and do something more than talk about "bedding Geraniums." The mention of bedding Geraniums brings to mind how these have absorbed public attention, and while the great improvements which have been made in them are admitted, they, even they, are regarded as being super-patronised—"overdone."

But what about Roses? Well, these during my few years of absence have really advanced, the love of them has increased, the cultivation of them has been perfected, and the exhibiting of them has been the scene of many a triumph and many a joy. If anything in the horticultural world has been "overdone" one might think it were the growing and showing of Roses. But no such thing is whispered; none can say anything against a good Rose, the charms of which are above mere taste and the virtues beyond reproach. Yet it is said that many a character of some Roses "written in French" has been "overdone," and that the "new" in Roses is not always better than the "old."

Nor is gardening in the new world better than it is in the old. We have flowers in the far west which are bright for a time, but they lack the continuousness, the freshness, and especially the sweetness of flowers "at home." Yes, England is "home" yet. Whether it is by lack of moisture in the ground, by extreme heat and an arid atmosphere, or all combined, I know not; but I do know that flowers of the gardens and flowers of the prairie do not possess, or at any rate diffuse, the "sweetness of breath" that flowers do in England. And after all they are the "old flowers," which are the sweetest as they are the hardest, the same as "old friends" are the firmest and most constant.

Such have been my thoughts since my return to "the west"—a land where there is no display of pride, where a man is not estimated by the number of rings which he wears, but for the work that he does; where gardening is improving every day; where flowers are spreading, and fruits and vegetables are increasing; and where those who aid in such pursuits which benefit a nation are regarded with that respect which is due to good services.

Of good service has your Journal been to me and many. It has taught us many useful hints, and given us wise counsel for many years. Though England in gardening matters had changed since I first left its shores, I found after a regular perusal of your pages the "old country" just as I expected to find it. Even the very designs of the "carpet beds" seemed familiar, and the sober nests of succulents, the golden lines of Pyrethrum, and the crimson carpets of Alternantheras scarcely evoked surprise as I examined them in "the parks"—parks which have been designed with so much skill, and are managed with so much ability, that, so far as my travels enable me to judge, there is nothing in the "old world or the new" to equal them.

Yes, you are in advance of us in gardening matters, but your advance on your own of a quarter of a century ago is an advance of "display" mainly. Is your present race of rising gardeners equal in solidity, in steady, plodding, working perseverance to those of the "old school"? Are the young training themselves to works of usefulness by thoroughly mastering the principles which govern the "old craft"—are they, in a word, "bottoming the business," or skimming the surface and relying on achieving reputations by "making a show"? If so, and I cannot help having a suspicion that such is the case, I shall continue to seek instruction from the "old hands," and wish them, and you, and all prosperity.—ANGLO-AMERICAN, Lafayette County, Wisconsin.

### BEDDING GERANIUMS.

THE Geraniums in the trial grounds at Chilwell are now showing their true character, and as some of them are better than others for flower-garden decoration, the following classification may be of service to some of your readers:—*First-rate*: Mrs. Turner, Mrs. Augusta Miles, Mrs. Holden, and Amaranth, pink; Dell and Corsair, scarlet; Shakespeare, Col. Wright, and Earnest, red; Rev. T. F. Fenn and Mrs. Mellows, crimson; Edward Sutton and General Outram, dark crimson; Mrs.

Jacoby, salmon; Lawrence Heywood and Mrs. Hole, magenta. *Second-rate*: Pink, Mrs. Fyfe; scarlet, Mrs. Hetley, John Gibbons, Rev. F. Aitkinson, and Mrs. Whiteley; crimson, Sir H. S. Stanhope, Bayard, and Col. Holden; cerise, John Fellows and Little Carr; rose, Mrs. Paget. *Third-rate*: Lady Byron, Lucy Bosworth, Mrs. Rogers, and Lady Sheffield, pink; Louisa Smith, rosy crimson.

It may be remarked that many which are not good for bedding are excellent when grown in pots under glass. Lady Sheffield, for instance, runs to seed immediately the flowers open outside, while in the conservatory it is all that can be desired.—J. M.

### VIOLAS.—No. 1.

THE Violas are an extensive family of plants, for the most part of dwarf or spreading growth, and possessing such a combination of flowers with foliage as to give a greater satisfaction to the eye than the beholding of bright unrelieved masses of colour, which may dazzle and fatigue but do not attract.

In Violas we have the sweet lovely Violet (*Viola odorata*), a native, in purple and white varieties, with the little-differing Russian Violet (*V. suavis*), only flowering at an earlier period. From these, with probably an admixture of the Chinese Tree Violet (*V. arborea*), in purple and white varieties, have arisen our improved varieties of sweet-scented Violets. No one seems to have paid any particular attention to this class of Violas until Mr. Lee of Clevedon took them in hand and gave us Victoria Regina, the best of all the deep blue or rather purple single Violets, being much larger and deeper in colour than Czar, also sweeter, commencing to bloom considerably in advance of that variety. Of Victoria Regina I gathered fine blooms on August the 17th of this year from plants which were rooted runners planted in April last, and these will give flowers until spring. Fine as Victoria Regina is it is far surpassed by Prince Consort, a lighter colour—a blue in fact, with a circular bloom, and of an endurance that has no equal in Violets. It commences blooming at the same time as Czar—namely, October, though I had blooms last year in September. I allude to these because it appears such a pity to cling so tenaciously to old favourites as the Russian Violet when there are others with very much larger, better shaped, and equally sweet or sweeter flowers, and stalks that admit of the flowers being readily bunched, and therefore more serviceable and enduring. No flower meets with readier acceptance and appreciation than the Violet.

The Pansy or Heartsease is another of the Viola family, associated with our earliest recollections. From the common Heartsease or Herb Trinity of our fields have been obtained by sowing and hybridising with other species the numerous varieties of the popular florists' Pansy. Viola tricolor varies considerably in a wild state, and has been greatly improved by the skill of the cultivator and hybridist. Most normal forms under high culture increase in size both of foliage and flower, and it is in these variations that occur sports—or departures from the original—which it has been the care of the cultivator, when the breaks were improvements on the parents, to foster and increase. It is hardly possible to take in hand any species of plant, especially of plants which are increased freely from seed, without improving its size and beauty. It is only a few years since the Viola cornuta became prominent through the efforts of Messrs. Wills, Bennett, and others, and after the lapse of a few seasons we are presented with varieties which for form and size are scarcely distinguishable from Pansies—in fact, some of these are no more like *V. cornuta* and *V. lutea* than are the bedding Pansies like *Viola tricolor*.

The genus Viola naturally divides itself into two sections—namely, the Violets and the Pansies. The Violets have the leaves mostly heart-shaped, though the foliage is occasionally pedate (*V. pedata*), and palmate (*V. palmata*), proceeding directly from the root or stem without forming a shoot, and perennial, the stem increasing slowly and upright, forming what are recognised as "trees," and are continued by runners rooting at a distance from the parents. In *V. cucullata* the plant is furnished with a tubercled root-stem from which arise the leaves and flowers without a stem above ground, producing only leaves and flowers. It is deciduous, losing its leaves in late summer; it is the latest blooming of the Violets, and continued this year into June. The variety I have is Mr. Lee's, there being several types or varieties of this the Hooded Violet. The flowers are large, of a deep purple colour, and very numerous. Unfortunately it is inodorous, but neverthe-

less is fine for moist yet well-drained slightly shaded rock-work, and for the open border in rich light well-drained soil. All the Violets have as compared with Pansies stout root-stems increasing with the age of the plants. In Violets the seed capsules seek the soil, their stems becoming prostrate—lying upon the ground with the mouth of the capsule downwards, but rising again when the seed ripens, and the capsules open. The capsule is much more round in Violets than in Pansies, and the valves are consequently more elongated. In Violets the leaves proceed from the root, or if from a stem they are opposite and simple, whilst in Pansies the leaves are alternate, simple, and furnished with permanent leaflets at their base, none of the Violets having leaflets at their base. The calyx in Violets is imbricate, in Pansies valvate. In the direction of the flowers Violets are more or less drooping and hooded, Pansies oblique. In Pansies the stems are annual, and are replaced by others from the root—i.e., suckers; in Violets the stems are perennial.

I will now remark that Violets remain as they were. No improvement has been effected except that resulting from cultivation and selection, and it is equally certain that no union has taken place between Violets and Pansies. Of the latter I propose to offer a few further views and cultural hints.

It is possible that the genus *Viola* may admit of division into more than two sections. Be this as it may, it appears pretty clear that *Viola cornuta* of Switzerland, *V. calcarata* of the Alps, and *V. grandiflora*, have an affinity to or for our *V. tricolor* and *V. lutea*, subjects not very distantly distributed as to climatic conditions. When we consider the freedom by which *V. tricolor* suffered itself to be ennobled into Pansies,—the credit thereof being due to a lady, Lady Mary Bennet, daughter of a late Earl of Tankerville, who in a small flower garden at Walton-upon-Thames in 1810 or 1812, assisted by the gardener, Mr. Richardson—we cannot help being astonished at the result. Mrs. Loudon in her pleasing sketch of the history of the Pansy in her "Gardening for Ladies," tells us about the great variety and beauty of the seedlings. The trade, in the person of Mr. Lee of Hammersmith, saw the advantage to be derived from the improved culture of the Pansy, and other nurserymen kept the "ball a-rolling," imparting to the flowers size, form, substance, purity of ground, and distinctness of colour, until the angular-petaled *Viola tricolor* could scarcely be recognised as the progenitor of the popular florists' Pansy.

It were not to be expected that a profusion of flowers destitute of good shape would be tolerated. Plants now employed for decorative purposes must be not only beautiful in the mass but have individual flowers which will bear the closest scrutiny. A species would no more be tolerated in a choice selection of Pansies than a Dog Rose in a border of Roses such as that selected from the Rose election; and no florist could view a *Viola*, much as he may admire its beauty, without setting to work and resting not until it be converted into his ideal of beauty.—G. ABBEY.

### SANDY AND DISTRICT FLORAL AND HORTICULTURAL SOCIETY.

THE eighth annual Exhibition of this flourishing Society was held on the 25th inst. in the park of Sandy Place, the residence of J. N. Foster, Esq., and it would be difficult to find a more suitable place for such a gathering, the park being studded with fine old trees, which in hot weather form a very inviting retreat to visitors. The well-ordered grounds of Mr. Foster were also thrown open to the public; the day was fine, and a large and fashionable company assembled.

The different exhibits were arranged in eight large marquees dispersed about the grounds. There were classes for farmers' grain, roots, dairy and other produce, market gardeners, cottagers, amateurs, gentlemen's gardeners, and nurserymen; poultry, cage birds, dinner-table decorations, &c. The Show throughout was a good one, although the vegetables were not so numerous as in former years, owing in a great measure to the late hot and dry weather, but those shown were of good quality. The show of fruit and flowers was very satisfactory, although there was a falling-off in plants, the collection of Mr. House of Peterborough not arriving owing to a breaking-down on the road.

There was a large show of Potatoes, and the way in which some of them were judged is worthy of imitation. They were boiled, some being peeled and some having their skins on. In this competition Early Rose carried off first honours. This variety is becoming very popular in this neighbourhood. The honey was a grand show, the premier prize going to Mr. Samuel Thorne, sen., Ashwell, Herts, for a glass super weighing 101 lbs.;

the second prize going to Mr. James Thorne, Ashwell. There were five entries for dinner-table decorations, the first prize going to Miss J. Pearson, The Hassels, Sandy; the second prize to Mr. Richardson, Sandy Rectory. In the market gardeners' class some good Onions, Carrots, and field Cucumbers were shown, the first prize for six Cucumbers going to Mr. D. Dickens, Old Warden. Heads of Onion seed were shown in sixes.

In cut flowers, Asters, Dahlias, Verbenas, &c., were not so good as usual, but noticeable were some stands of very fine African Marigolds. Roses were both scarce and poor except in 48's, and in this class Mr. Prince of Oxford staged good blooms.

Collections of vegetables in eight varieties were good and well arranged, as also were the collections of fruit in six varieties. The show of Grapes was not large but good, the first prize going to Mr. Telbrook for two well-developed bunches of Black Hamburgh, but rather deficient in colour. Good bunches of Muscat of Alexandria were shown, but in an unripe state. The show of Red and White Currants and Gooseberries was very good. There were nine dishes of Cherries, twenty-six dishes of Plums, and forty-two dishes of Apples, the first prize going to Bedfordshire Foundling. Several good dishes of Tomatoes were shown. Of Cucumbers there were eighteen brace of immense size, but, as a rule, coarse. Tender and True carried off the first prize. Peaches and Nectarines were good, and the same may be said of Melons, of which seventeen fruits were staged. Owing to the delay in making the awards the names of the successful competitors could not be obtained.

### ANNIVERSARY OF THE WIMBLEDON GARDENERS' SOCIETY.

THE second "session" of this new and flourishing Society was opened on the evening of Friday, the 25th inst., by about fifty of the members, who celebrated the occasion by a "knife and fork entertainment," and after proceedings which may be described as socially educational. This institution is worthy of note, and a brief recapitulation of its establishment and progress may be usefully given, as affording encouragement to gardeners in other districts seeking a wholesome mode of uniting together for self-improvement and the general advancement of the craft in which they are engaged.

As to the desirability of gardeners meeting together to discuss congenial topics there cannot be a dissenting voice, provided that the same strict care is taken as at Wimbledon to eschew even a savour of that peculiar kind of "unionism" which has destroyed so much good feeling between employers and employed which formerly existed. At Wimbledon, as Mr. Ollerhead took occasion to say, "the objects of the members of the Society were at first misunderstood, and the union of the gardeners was interpreted by some as a union of that kind which the best of employers regard with abhorrence, as also did he as a gardener, and equally did the friends acting with him in re-establishing the Society. Their sole object was self-improvement, their one and only desire being to become more proficient in their calling—to become, in fact, better gardeners, and so render their services more acceptable to those having or requiring them. That was their sole aim and ambition, and they had no ulterior object in banding themselves together. Since their motives had been better understood, aids in the way of gifts of books, &c., had been forthcoming, and he felt sure that the Society would be so conducted as to secure further patronage and assistance from those who would in the end share in its benefits in having the services of competent gardeners, or those engaged in adopting every means at their command in making themselves proficient."

Such sentiments have the right ring about them. That they were expressive of the views of all the members assembled was clearly manifested. A society founded for such an excellent object is certainly worthy of support, and is almost equally certain to be supported. Were similar efforts made in other districts to enhance the knowledge and improve the status of the gardeners good could not fail to result therefrom. It is not, however, every district that contains a sufficient number of gardeners in a limited area to form a society which can be self-supporting; but in some localities this obstacle may, perhaps, be surmounted by co-operating with some already established kindred institution, and in this respect the establishment of the Wimbledon Gardeners' Society affords a useful lesson.

At Wimbledon there had been a gardeners' society for some years, but it was weak and in a measure effete. Sir Henry Peek kindly permitted the few members to meet for discussion in the young men's rooms in the gardens at Wimbledon House. The members attending these meetings not being so numerous and active as desirable, Sir Henry spoke to his gardener, Mr. Ollerhead, by way of resuscitating the Society, and suggested the possibility of making arrangements with the Committee of the village Reading Society for the use of their lecture hall. This being in the ordinary course of business too costly, it occurred to Mr. Ollerhead to enter into an alliance with the

village Society, and eventually it was decided that if thirty gardeners could be induced to enrol themselves, the managers of the village Institute would accept them as ordinary members, and, in addition to the general literature would provide them with a certain number of gardening periodicals, permit them the use of the lecture room for the reading of papers and for discussion, and allow them to establish a library of gardening books. The stipulated number of members soon became doubled, and the gardeners became a source of strength to the Society which opened its doors to them, and thus assisting it more completely to fulfil the purpose for which it was established—as an institution for the general improvement of the industrial classes of the district.

The alliance has been most successful. The Committee and Secretary of the Institute have rendered every assistance and granted every facility in their power for the gardening contingent, and the gardeners have already formed a library including the most practical and useful books in publication. These advantages—the garden and general library and reading room—are at the disposal of all gardeners for the easy subscription of 5s. per annum, and in order to participate in them some members come long distances to attend the meetings and discussions. Especially is this so with head gardeners, who have been quick to perceive the advantages offered, and it is to be hoped that all the young men of the district will follow the excellent example that has been set them. Acting alone and without the aid of the village Institute the Gardeners' Club could not have been in the satisfactory condition that it now is, and without the gardeners the Institute could not equally well carry out the intentions of its founders and managers. Thus the alliance has proved one of mutual help, strength, and benefit.

The success of the amalgamation may well be recorded, for the plan which was adopted, and which has been carried out so well, is adaptable to other localities, and similar attempts at self-improvement cannot fail in adding to the benefits of those who are especially desirous of seeing competent and prosperous—the gardeners of Britain.

The opening meeting was a very enjoyable one, and an impetus was given by the remarks of the various speakers to the strengthening of the Society, and making it additionally useful and flourishing.

Mr. Wright of the *Journal of Horticulture* was called upon to preside at the meeting, and was supported by Mr. Gordon of the *Gardeners' Magazine*; Mr. Casswell, the Secretary of the village Institute; Mr. Kinghorn, Sheen Nursery, Richmond; Mr. Ollerhead, gardener to Sir Henry Peek, Bart.; Mr. Lyon, gardener to A. Schlusser, Esq.; Mr. Moorman, gardener to the Misses Christy, &c.

### THE ROSE ELECTION.

I SHOULD be glad of all replies to this as soon as possible, as I am anxious to get the result out before the end of September, and I shall therefore be extremely obliged to all those who intend to kindly assist if they will send me their lists without delay.

1, Name what you consider the best fifty Roses in cultivation, underlining the best twenty; and

2, Which do you consider the best stock for Roses?—  
JOSEPH HINTON, *Warminster*.

### ASPECTS OF NATURE.—AUGUST.

OF all months of the year August is richest in colour, for not only are the hues of the wild flowers more brilliant than in spring, but the fields of golden grain are at their brightest and offer a splendid contrast to the surrounding greenery of hedgerow, copse, and wood. The reaper cuts both corn and flowers, and beneath his glittering scythe or sickle fall some of the most beautiful blossoms of the floral garland which twines with an unbroken chain the circle of the months. Spenser thus describes August—

"Being rich array'd  
In garments, all of gold down to the ground,  
Yet rode he not, but led a lovely mayd  
Forth by the lily hand, the which was crown'd  
With ears of corn, and full her hand was found."

Full indeed during this most bounteous month, when not only the cultivated fruits are ripening in every orchard and on every garden wall, but when the clusters of Hazel nuts begin to gain a deeper tint, when the Bramble has its white or pinky-white blossoms, and its pleasant fruit changing from green to deep purple.

In the corn field the most gorgeous flower of all is the Corn Marigold; indeed, during this glowing month a bouquet of wildings—as rich in colour, if neither so sweet in perfume nor so large in size as the more favoured occupants of the parterre—may be culled. For gold we may gather the brilliant Corn

Marigold or yellow Oxeye; for blue, as bright and beautiful as though reflected from the unclouded ether above, the Centaurea Cyanus, known by so many names—Cornflower, Hartsickle, Blue-bonnet, and which the poet has apostrophised as Love's Oracle.

"There is a flower, a purple flower,  
Sown by the wind, nursed by the shower,  
O'er which love breathed a powerful spell,  
The truth of whispering hope to tell.  
Now, gentle flower, I pray thee tell  
If my lover loves me, and loves me well,  
So may the fall of the morning dew  
Keep the sun from fading thy tender blue."

For deep crimson the splendid blossoms of the Saintfoin, which, though it is a cultivated plant and much beloved of the farmer for fodder, still escapes and grows up in odd places; for the white the effective Ox-eyed Daisy may be chosen. We may gather such a nosegay from plants that grow on either side of many a field path, and nothing will excel its brightness.

Where such strong contrasts are not desired the hedgerows offer numberless plants, less conspicuous doubtless, but scarcely less beautiful, being distinguished by variety of form, colour, or peculiarity of habit. The field *Convolvulus* now covers many a waste place, clothing with beauty the most unpromising spots, and displaying its pretty pale pink petals day after day, as though the store was endless. But the *Convolvulus arvensis*, delicate and pretty as it is, has a favoured rival in the splendid large white Bindweed of the hedgerow, which grows so profusely and luxuriantly. A pretty effect may be produced where this wilding is abundant in garden hedges by placing a few pea-sticks for it to run up; the *Convolvulus* will twine gracefully around the sticks, and will repay the kind attention by forming a screen of graceful green leaves and snow-white flowers until frost comes to cut down unnoticed weeds and carefully tended blossoms indiscriminately.

On the chalky cliffs which round in the Bay of Broadstairs, in the Isle of Thanet, the beautiful crimson flower commonly known as Rambling Widow grows in profuse red patches of bloom, which hang over the edge of the cliffs towards the sea. In the same district also, but not quite so near the sea, the lovely blue flowers of the wild Chicory and the pale lavender Scabious—which has so little in common with the cultivated variety, wanting both its velvety appearance and Musk-like scent—may be gathered. The Red Campion is a pretty flower, though its bloom has a somewhat loose and rugged appearance; but it is little known, being outvied in brilliancy and popularity by the scarlet field Poppy.

The common yellow Goat's-beard of the fields is in many places known only by the characteristic term of "Go-to-bed-at-noon," from the opening and closing of its flowers at certain hours of the day, and which inspired Linnæus with his idea of a botanical clock. Mrs. Hemans has perpetuated the remembrance of the *Horologium Floræ* in the following beautiful lines:—

"From such sweet signs might the time have flowed  
In a glorious current on,  
Ere from the garden, man's first abode,  
The glorious guests were gone.  
"Yet is not life in its real flight  
Mark'd thus—even thus—on earth,  
By the closing of one hope's delight,  
And another's gentle birth?  
"Oh! let us live, so that flower by flower,  
Shutting in turn, may leave  
A lingerer still for the sunset hour,  
A charm for the faded eve."

The Marsh-mallow may now be seen in full flower, and where the petals have fallen the country children pick the round flattish seed vessels and call them cheeses. In France the Marsh-mallow is very highly esteemed as an emollient in cases of slight cold or cough, and every nurse and every housewife knows how to make Tisane de Mauve and Tisane des Violettes, both sovereign domestic remedies in constant request during the uncertain spring weather.

Some of our summer visitors now begin to leave us. The swifts are the first, evidently liking to live in a perpetual spring, for as yet these cannot be driven from our land for the lack of food, for the air is filled with insect life, nor has the warmth of the atmosphere diminished, except during the night. The rooks also, which have remained abroad during the hot evenings of summer, now return to roost in their nest trees; and the robin, which has with the rest of the merry songsters been silent some time, resumes towards the close of the month his warblings, to cheer the shortening days with his lively winter notes. The warm autumn nights, when no leaf is

stirring and all nature appears hushed in repose, is the season when the shrill chirp of the cricket is heard striking somewhat discordantly on the perfect quiet of the air, which can scarcely be said to be disturbed by the trumpetings of the innumerable gnats,

"Which, drawn by milky steams at evening hours,  
In gather'd swarms surround the rural bowers.  
What time the glad some nymphs in chorus sung,  
Rose-gilded legions glittered in the sun."

When the corn is gathered and the harvesters rest for a while from their labours the work of the sportsman begins; but on the breezy hill sides and among the purple heather on the moors, where, during the still warm days, the grouse and the plover have reared their young broods, the report of the death-dealing gun is heard, and terror and dread reign where so lately all was peace and happiness.

We see the changes of the month as each follows each in turn; we note the distinguishing plants that come and go—the insects that are awakened to life in the spring, that buzz during summer and disappear during autumn—while we almost forget the little flower with silver crest and golden eye which blooms always and everywhere, which "hides in the forest, haunts the glen," grows along the margin of the dusty road, blooms undisturbed over the graves of those who rest in peace in God's acre, and ever perks up its little head on every trodden spot in close vicinity to towns and cities.

"Tis Flora's page—in every place,  
In every season fresh and fair;  
It opens with perennial grace,  
And blossoms everywhere.

"It smiles upon the lap of May,  
To sultry August spreads its charms,  
Lights pale October on its way,  
And twines December's arms."

—T. S. J.

## WOLLATON HALL.

THE RESIDENCE OF H. AKROYD, Esq.

WOLLATON HALL is situated about two miles and a half west of Nottingham. It occupies a commanding position, and can be seen in almost every direction. It is in the centre of a grand old park of seven hundred acres, which is enclosed with a brick wall from 7 to 10 feet high. The Hall is approached from Nottingham either by the way of Lenton or by Old Radford, the latter affording the readiest access to the gardens. The Lenton entrance is by a lodge of commanding proportions, and in character with the noble structure within the grounds.

It is impossible to approach the mansion on either side without being struck with its magnificent proportions and the richness of its details. It is supposed to be one of the most beautiful mansions of "England in the olden time." It is entirely built of freestone, which came from Ancaster in Lincolnshire, on the backs of horses, in exchange for coal produced by the mines of the estate. The building is square with four large towers adorned with pinnacles, and in the centre the body of the house rises higher, with projecting coped turrets at the corners. The front and sides are adorned with square projecting Ionic pilasters. The interior is on a grand scale, has many stately apartments, and contains a very extensive and valuable collection of paintings by the best masters. Every front of the main building and every side of every tower is richly decorated, so as to present a very superb whole. The park is broken into gentle swells, and in some parts is beautifully wooded, admitting some picturesque and extensive views of the surrounding landscape. It is well stocked with deer, and from the flower garden is seen a fine sheet of water enlivened with swans and other aquatic birds.

Passing by the west side of the Hall there is a sunken way, which lies between the Hall and the stables, and being overhung with shrubs and trees it is entirely hidden from view. This road leads to the large conservatory at the south-west corner of the Hall, and the flower garden in front falling gently towards the park. Between the conservatory and the gravel walk there is a broad ribbon border filled with spring flowers, and though when seen it was past the middle of June it was a sheet of floral beauty. Beginning at the back there were two rows of Cliveden Blue Pansy, then two rows of *Viola lutea* followed by two rows of red Daisies, then a row of *Arabis variegata*, next a broad band of *Aubrietia*, succeeded by a row of *Saxifraga umbrosa* with another row of Golden Feather *Pyrethrum*, then *Sempervivum californicum*, and the outside row of *Saxifraga hypnoides*. The flower beds were also all aglow with spring flowers, and for general effect Mr. Gadd

depends more on Pansies than any other plants. There were many mixed beds, but Pansies were the chief feature. I noticed one large bed of Pansy Purple Prince, very effective; another of Purity, equally good; another of Chrome Yellow, all masses of bloom. Then there were several beds filled with dark seedling Pansies which were very gay and attractive. Other beds were filled with Daisies of sorts, *Aubrietias*, Golden *Pyrethrum*, Imperial Blue Pansy, and the Variegated Thyme. Among the many plants used for the embellishment of the spring garden there is none more effective than the Variegated Thyme, *Thymus citriodorus aureus marginatus*. On a narrow strip of grass that skirts the park I observed several long narrow beds planted so as to match with each other. The outside row was *Veronica incana*, with an inner circle of *Aubrietia*, next Golden *Pyrethrum*, then a ring of Forget-me-not, and the centre Wall-flowers. The flower garden is well sheltered on each side by banks of evergreens and *Rhododendrons*, the front of it being open to the park.

Turning into the conservatory I found a fine collection of *Camellias* planted in the borders, many of them being 8 and 10 feet through and 10 and 11 feet high. I cannot enumerate all the noble specimens, but amongst them were *Chandleri* 13 feet high, *Countess of Orkney*, *Mathotiana*, *Mathotiana alba*, *Contessa Lavinia Maggi*, *Lady Hume's Blush*, *Imbricata*, *Double White*, and many others. From the roof was suspended the charming *Maréchal Niel* Rose, *Bignonias* and *Tacsonias*. To the left of the conservatory is the Rose garden, but I was there too soon to see the Roses in beauty. This garden is encircled with *Rhododendrons*, which were in full bloom, and these were backed with fine old Cedars of Lebanon, which were interspersed with *Lucombe Oaks* and grand old Yews. Following this walk we come to a fine piece of open lawn, studded here and there with excellent specimens of *Cupressus Lawsoniana* and one or two specimens of Purple Beech that it would be difficult to surpass. Coming to the terrace walk, on the left there is a broad bank of *Rhododendrons* about 9 feet high and 10 or 12 feet wide, and now and then a white Broom jutted out from amongst the dark foliage and mass of bloom; and down the centre is a row of standard plants of *Acer Negundo variegata*. At the termination of this walk a fine prospect opens on the vision. There are avenues of Elms and Limes radiating in various directions, with the deer reclining beneath their umbrageous branches, giving the whole scene a charming park-like appearance. Turning to the left we ascend the upper terrace, and now the fine architectural proportions of the mansion come out in all their magnificence. In proximity to the mansion I observed some venerable Oaks and Cedars, and one copper-coloured Beech was 225 feet in the circumference of its branches. In the park is an evergreen plantation consisting of *Piceas*, *Wellingtonias*, and other choice Conifers, each having been planted by some member of Lord Middleton's family.

The kitchen gardens and forcing departments are some little distance from the mansion. Near Mr. Gadd's residence is a fine piece of pleasure ground surrounded with *Rhododendrons*, which at the time of my visit were a mass of glowing beauty. Among the most conspicuous of them I noticed *Lady Eleanor Cathcart*, *Luciferum*, *Nero*, *Brutus*, *Blandyanum*, *Alarm*, *Vandyke*, *catawbiense fastuosum*, *C. Everestianum*, and many others equally good.

We now pass on to the large conservatory, which is 15 or 18 feet high and 75 feet long. Besides *Camellias* I noticed a fine plant of *Araucaria Cunninghamii*, large *Azaleas*, and a general collection of greenhouse plants. In front of this conservatory there is a large herbaceous garden, and here many favourite old plants are petted and cared for. There was the beautiful *Spiraea Douglasii* with its dense plumes of white flowers; *Aquilegia glandulosa*, one of the most beautiful plants of the genus; *Anthericum Liliago*, a pretty free-flowering perennial, with grass-like foliage and numerous spikes of white flowers; *Lithospermum prostratum*, a fine plant for the hardy flower garden; *Phloxes*, *Delphiniums*, double *Pyrethrums*, plants of great beauty; large *Azaleas*, *Paeonies*, *Potentillas*, and *Dodecatheon Meadia*. The walls of the old conservatory were draped with *Magnolias*, *Wistarias*, and *Chimonanthus fragrans*.

Pursuing our journey we reach the kitchen garden. The walls are all clothed with beautifully trained fruit trees, and the various flats were teeming with luxuriant vegetables. There are several walls devoted to *Apricots*, which are protected in spring with broad coping boards resting on projecting brackets at the top of the wall. *Peaches*, *Pears*, and *Plums*

are well represented, and every tree is in the best possible condition. I hardly know which deserves the greatest meed of praise, the wall trees or the vegetable crops: both bore the impress of superior skill. I was much struck with a flat of Sutton's Queen Broccoli, which was invaluable as a very late Broccoli. Many of the heads measured 36 inches and upwards in circumference, and they were close and compact. A flat of Hicks's White Cos Lettuce was something wonderful, the Lettuces were so large and fine. The Strawberries promised abundant crops of fruit, a large quarter of the old Black Prince being grown for preserving, and Sir J. Paxton and Eclipse are good for table purposes. Early Prolific was not very promising in the open ground, but as a forcing Strawberry Mr. Gadd considers it without an equal. Strawberries are forced extensively, and at the time of my visit (June 17th) they were a grand sight. On the south wall there is a range of lean-to

houses 480 feet long, divided into eight compartments of Peach houses and vineries, and every available spot was occupied with French Beans and Strawberries. These houses were in the same good keeping as the rest part of the garden.

At the west end of the kitchen garden there is another block of useful span-roofed houses; the first being a Pine house, 60 feet by 13 feet, and well furnished with young Pines in luxuriant health. The second is a Melon house 30 feet long, the fruit in various stages of growth. The chief varieties grown were Read's New Hybrid Scarlet-flesh, a beautiful netted variety of most delicious flavour; and Eastnor Castle Green-flesh, a hybrid between Beechwood and Victory of Bath, a delicious variety, the plant being a free grower and setter. There was also in this house a miscellaneous collection of stove plants. The third house, 30 feet long, contained Cucumbers. Rollisson's Telegraph and Pearson's Long Gun appeared to

Fig. 24.—WOLLATON HALL.

be relied on for the main crop; but there were several plants of the Duke of Connaught and Tender and True, the latter proving a first-rate Cucumber. Two or three days before my visit Mr. Gadd cut three fruit from a plant of Tender and True which measured 7 feet. In the Palm house I noticed in particular a fine *Passiflora Buonanaparte* blooming in great profusion, and a *Clerodendron splendens*. In the show house, which is 75 feet long, there were huge *Brugmansias*, Tree Ferns, Musas, healthy Orange Trees, &c., and from the roof were suspended Climbing *Devoniensis*, *Gloire de Dijon*, and *Maréchal Niel* Roses. The Fern stove was furnished with a fine collection of healthy well-grown Ferns interspersed with *Gardenias*, which filled the house with the most delicious odour. On the roof were *Hoya carnosus*, *Jasminum Sambac*, *Rhynchospermum jasminoides*, and *Stephanotis floribunda*. In the large plant house there was a large collection of *Pelargoniums* of the greenhouse section, and the same may be said of the Zonals. The New Holland house was filled with hardwooded plants, *Ericas* and *Epacris* predominating. The pillars were draped with *Tropaeolums* of the Lobbianum section. The stove, 35 feet long, was crowded with such plants as are used in the present style of dinner-table and house decoration, all in excellent health. The last house I entered was a successional Pine house.

Behind the range of vineries and Peach houses there is a very commodious potting shed heated with hot water. It is

rare in noticing gentlemen's seats that the potting shed comes in for a note of observation, but that at Wollaton is well worthy of imitation. In a shed of this description plants may be brought from warm structures in cold weather either to be repotted, sponged, or staked, and the work can be performed without danger to the plants and with comfort to the workmen. There is also a convenient place for fumigating, which must be a great advantage when only a few plants are infested with insects, or when it is not convenient to fumigate them in the house in which they are growing. The fruit room is also a model of perfect arrangement. All the trays are moveable, and fifty bushels of fruit can be stored away in single layers. On a bed of coal ashes I noticed a fine batch of *Chrysanthemums*. Mr. Gadd grows these plants on single stems; they are never stopped from the time they come from the cutting pot, and he succeeds in producing flowers of prodigious size.

I have dwelt longer on these gardens than I intended, and now the notice is very imperfect, there are so many objects of interest deserving to be recorded. I wended my way across the park and kept by the Lenton lodge. From the mansion to the lodge it is about a mile and a quarter. There is a noble avenue of Limes about three-quarters of a mile long—"tall ancestral trees"—planted on each side the carriage drive, the branches meeting overhead and forming a leafy arch of great beauty. From the Limes to the lodge there is an avenue of

Wellingtonia gigantea half a mile long, about 10 or 12 feet high, but they will never equal in beauty the splendid avenue of Limes.—R.

### PYROLA ROTUNDIFOLIA.

OUR figure represents one of the most charming families of dwarf-growing hardy plants in cultivation. They are by no means a numerous race, but it sometimes happens that the less in number are the species the greater is the interest attaching to them. The greater number of these plants are natives of Britain, while some are from North America and the Pyrenees; but no matter where they are from, they form one of the choicest groups of plants that we possess. Why they have remained so long in background and been excluded from our rockeries and other shaded situations is to me incomprehensible. Their evergreen pear-shaped foliage is a sufficient recommendation for them, to say nothing of their spikes of white and other coloured flowers. They are met with in shaded and sheltered alpine regions among decaying vegetable matter. They are very accommodating when taken in hand for decorative purposes, and they are fine for exhibition in the spring and summer. Afford them the elements under which they are found, and then success is almost a certainty.

They are admirable plants for cool ferneries under glass in the shade, but they are impatient of wet, and must be provided with efficient drainage. A mixture of peat, leaf soil, and coarse grit is a suitable compost for them to grow in, but with the best attention we sometimes have the reward of foliage only, or accompanied with only very few flowers, while at other times we are richly rewarded with a full supply of beautiful flowers. They are charming flowers for the bouquet and any other decorative purpose for which cut flowers are adapted.

They are increased by seed and division, which is best done when the plants have done flowering. The kinds most generally met with are *P. media*, *P. minor*, *P. rotundifolia*, *P. secunda*, and *P. elliptica*, but they are all worthy of culture, and ought to have a place in all collections of rock and border plants.—N.

### GRAPES AT KEDDLESTON HALL.

YOUR correspondent "E. C." was perfectly right in last week's Journal when he said the Grapes of this place were very noteworthy. I saw them the other day, and I must say they are the most remarkable crop of Black Hamburg Grapes I

have ever seen. There are a good many vineries about the place, but at present I will only notice two of them, or one in particular. This one is 40 feet long by 8½ in width. Sixteen years ago it was planted with Peach trees. The border was made to suit them with common garden soil mixed with a quantity of decayed vegetable matter from the rubbish heap. This border was only made 2 feet deep and 8½ wide. Peaches were planted on the back wall, and still grow and do well there.

As the exposure is due south it was found intensely hot inside in the summer time. To secure a partial shade Mr. Jackson the gardener planted a Black Hamburg Vine at the front and in the centre of the house. At first the canes were trained along each way from the centre to the two ends of the house, and when this was accomplished a rod was taken up each of the 11-foot rafters, which are 9 in number. This is the form of the Vine at the present time. It has invariably produced and finished splendid crops since it came into a bearing state some twelve years ago. Nearly every year there have been bunches cut weighing over 6 lbs. This year there are fifty bunches on the Vine; one or two of them have been cut which weighed 5½ lbs. each. About half the number on the Vine will reach this weight, and the remainder will at least run from 3½ to 4 lbs. Altogether the bunches must average 4 lbs. each, which brings the entire crop on the one Vine over 14 stones. The bunches are all well formed; the berries very large, well coloured, and not the remotest sign of shanking or any other kind of disease about them. The leaves, too, are healthy and green and of great substance.

From the first to the last the border is watered with manure water drained from rotten dung. In the hot weather the border was co-

vered to the depth of a few inches with cut grass from the lawn. No doubt the roots must have passed into the outside border, which is 8 feet wide; but this has no special treatment for the benefit of the Vine, as it is cropped with Potatoes or some other kind of vegetable annually.

It may be as well to remark that the Vine is started slowly into growth in March. There is only a flow-and-return 4-inch pipe in the house, therefore a strong heat cannot be maintained early in the season or in cold weather. The only time the Vine is syringed is during the period it is in bloom.

The other house to which I have referred is the same width, but 45 feet in length. Peaches are also growing in this one, and there are two Black Hamburg Vines planted in the front. They are trained in the same way as the single one. The bunches in this house will average from 3 to 4 lbs., and they are equally as well finished as those in the first house. The treatment they receive in this house is precisely the same as

Fig. 25.—PYROLA ROTUNDIFOLIA.

in the former, and Mr. Jackson can only attribute the slight deficiency in the one from the other through having to restrict the two Vines more than the one.

This is a very strong case in favour of the extension system of Vine-growing. Lord Scarsdale takes a great delight in his Grapes, and well he may, as better crops no one need desire to possess or see. Just fancy going into a house 40 feet by 8½, and being able to cut from twenty to thirty bunches of superb Black Hamburgh Grapes, and not one of them under 5 lbs. each.—J. Muir.

### SMALL FRUITS IN TREE FORM.

MANY of our most prominent pomologists have taken the ground that fruit trees of every description succeed best in our hot dry climate when allowed to branch from the ground; that the action of the sun's rays on the long naked trunk is highly injurious to its health and productiveness. Some even go so far as to say that the Apple, the most reliable of American orchard trees, will yield a far larger profit and show a higher state of vigour when trained in the shape of a large bush than when trimmed up as a tall standard, and they bring such convincing proofs as the growing trees to sustain their arguments. That there is a great deal of truth in this reasoning as well as notable exceptions to the rule we are forced to admit; but the system, as a system, is correct, and should be more generally carried out by our fruit-growers in training their young trees.

One of the most curious instances of the standard form yielding better results than the dwarf is exemplified in the new standard Currants and Gooseberries now on exhibition at the Centennial grounds in Philadelphia. These pretty little trees, for they are exceedingly ornamental, were planted in one of the beds the past spring, have received no extra care either in mulching or watering, and yet they have made a fine growth in every instance, and perfected very large crops of superior fruit. An unanswerable argument in their favour so far is, that there has never been the least symptom of mildew either on foliage or fruit, but whether this feature will remain permanent has to be tested; it seems really too good to prove true. Seedlings from the Lancashire varieties raised in this country will frequently produce perfect fruit for a few years, and then fall into the evil ways of their parents; grafted in the manner described, however, this disease may not attack them, and we hope for the best.

The stock used for the purpose is the common Missouri Currant (*Ribes aureum*) trained to a single stem, and it is astonishing how the grafts appear to favour this species. The originator claims that the influence of the root is what prevents the mildew from appearing, and I see no cause to doubt his arguments, as seeing is certainly believing. These little trees are not entirely new in this country, as they have been tested in New Jersey for several years past, and with the most complete success so far. It is indeed a novel and very ornamental sight to see these miniature trees with their weight of fruit depending from the branches, and in some instances with both Gooseberries and Currants in tiers one above another of the largest size. Charles Downing, who will not lend his influence to a doubtful fruit, has given them his endorsement, and Dr. Siedhof of New Jersey has been growing them for more than seven years to his entire satisfaction.—(*New York Tribune*.)

### ORNAMENTAL AND USEFUL TREE-PLANTING.

No. 3.

THE eye is familiar with the Lime in walks, avenues, and squares, where, under favourable conditions, it has a striking and graceful effect, and special attractions in the fragrant scent of its flowers and the summery hum of the bees as they sip their honey. The smoker knows no choicer rendezvous than the Lime walk for the enjoyment of a quiet "weed;" and a specimen of a very perfect Lime walk with interwoven canopy may be seen in the gardens of Trinity College, Oxford. The drawback to the Lime is a freakiness of growth in even the clays and gravels that are said to suit it best. A considerable difference will occur between two Limes in the same avenue, and the disparity from the Elms, which were probably planted at the same date, will be found much greater in some than others. A feature, too, which does not enhance the beauty of the Lime, though it has a solid *raison d'être* as an asylum for small birds, is the dense thicket of twigs and shoots which often grow out of its very centre or heart. Still the Lime may claim to be an ornamental tree; whilst its uses, in-

dependent of its honey-cups and the "bast" which it furnishes for mat-making and plant-tying, consist in supplying the best of woods for the carver, the smooth-grained, insect-proof, pale-yellow material, which yielded such delicate and enduring handiwork to the touch and under the graving tool of Grinling Gibbons. Specimens of this are to be seen at Chatsworth, Windsor, and St. Paul's, with the lines still fresh and sharp after a lapse of two hundred years; and another splendid example of this famous artist's skill is the carving in the saloon and rooms adjoining it at Holme Lacy, Herefordshire. Another use of the Linden wood is for the sounding-boards of pianos, as it is less inclined to warp than other timber. The *Tilia alba* is a variety of the *T. europæa*, with a silvery under-leaf; and there is an American Lime which differs from the European in having its young shoots brown instead of bright red.

Walk we next into the Beech woods for the charm of dryness under foot, and in autumn the yellow and amber tints overhead, no less than for the grace and nobility of contour which no tree critic except Gilpin has attempted to deny. Precedence might be claimed for the Sweet Chestnut, but that is a naturalised alien; whereas, but for Cæsar's statement that there was no Beech in England, we should claim it as a native. As park timber, in clumps, pairs and triplets, it has a fine effect; and though ill suited to mix too much with other trees will thrive apace amidst its own kind. It makes the best and densest of hedges, except the Yew and Holly, and there is no tree better for a screen fence. In habit it varies with its conditions. Drawn up by contiguous trees, its clean straight stem of a smooth olive grey is eminently graceful, as witness the two giants of straight and branchless trunk, named the King and Queen, at Ashridge, Lord Brownlow's seat in Herts, the finest samples of their kind in England. Where, however, it stands alone, its form is that of an expansive round-headed tree, apt to be short of stem, but having its head composed of crowding branches, which bend, curve, and inarch in various fashions. The finest example probably of this type in Europe is a Beech at Newbattle Abbey, near Edinburgh, with a bole of 33 feet at 2 feet from the ground, a height of 160 feet, and an overspread of branches not less than 120 feet in circumference. Its lower branches arch over till they reach the ground, when they assume an upright growth, disguised in summer by ample foliage. This tree, planted according to tradition in the sixteenth century, is an exception to the rule that the Beech, which reaches its prime at seventy or eighty years, decays rapidly after a century or a century and a half. An illustration of it is given in the *Gardener's Chronicle*, October 24, 1874. The Beech grows kindest on chalky soils, as in Kent, Berks, and the midlands; but it does well on clayey loam and generally where the subsoil is dry. Had we space, it might be shown that mycologists and entomologists have their special interests connected with the Beech; but it must suffice us to notice a form of disease to which it is subject, and which we have not seen noticed in the books on arboriculture. This is a woolly white mould upon the bark of tall clear-stemmed trees, resembling in appearance the American blight on the Apple's bark. It is said to be curable by copious dressings of oil; but the remedy is a laborious one, and in the meanwhile trees thus affected pine and shrivel. A notice of the Beech would be incomplete without a reference to the Purple Beech, and its sub-variety the Copper Beech, which are such effective contrasts to the green leaves of the garden and lawn in all their phases of colour. Our trees of this kind are produced chiefly by in-arch grafting from the stock of the original tree discovered a century ago in a wood of Germany. A weeping Beech and a variety with leaves blotched with yellow or white are worth consideration.

Linnaeus and his contemporaries regarded the Sweet Chestnut as a species of Beech, from which, however, it differs generically in having long and cylindrical and not globular catkins. For its well-girthed twisted trunk, broad leaves of a dark glossy green, and comparatively lightsome head, the *Castanea vesca* is entitled to rank amongst the trees of the park, though it is no match for the Oak or many other timbers in durability and soundness. On deep sandy loam or a rich gravel it is good timber enough up to thirty-five or forty years, and does well for gates and rails, or at a much earlier date for hop-poles and barrel-staves. But after fifty or sixty years, dialling or decay is apt to detach the annual layers from each other, and the tree becomes shaky. Its economic virtue is, strange to say, its precocity. In France, Spain, and Italy, from which last the Romans probably brought it

hither on that account, it is valued for its fruit, which makes a species of flour, and serves the purpose of our Potato; but with us who cannot grow *les marrons* of our neighbours, it is simply a dessert fruit, and even then rarely home-grown. It is propagated from the nuts when well ripened; but the tree has but a moderate amount of flavour in this country, and not such as one might expect from the size of ancient samples of it at Croft Castle—where some of the Chestnuts are from 76 to 80 feet in height, with a girth of 25 or 26 feet—at Nettlecombe in Somersetshire, and in Dean Forest and its border. The Tortworth Chestnut on the other side of the Severn was a boundary tree in Stephen's reign, and is computed to have seen eleven centuries. It bore fruit small but abundant in 1788, and in 1721 was 19 yards in circumference; but it is now very dilapidated, and its girth of 60 feet at 4 feet from the ground is a trifle to the famous Chestnut of Mount Etna, the *Castagna di cento cavalli*, which was 204 feet in girth, and of the capacity of which the name gives an idea. But the Sweet Chestnut's claim to consideration is its picturesque effect at other seasons, as well as in its autumnal leaf, which abides longer and is of a richer gold than its namesake the Horse Chestnut (*Æsculus hippocastanum*), a much later introduction to Great Britain from Thibet, of much less value as timber, and of a wholly different botanical family. The sole likeness is in the form, not the savour of the nut. The merit of the Horse Chestnut, which commends it for environing walks, drives, and lake banks, is its massive and luxuriant foliage, especially when "the richness of its velvet drapery is embroidered over with millions of silver flowers." Compared with these clusters of delicate white, tinted and relieved by as delicate pink and gold, the blossom of the Sweet Chestnut is dull and flat. For a charming variety of the Horse Chestnut the roseate-tinted *C. rubicunda* may be easily grown, as also the less known *Pavia lutea*, a smooth Horse Chestnut of elegant foliage and habit. We may mention, too, a variety of the Sweet Chestnut likely to prove quite hardy, the *C. chrysophylla* introduced from California, which is remarkable for its bright golden-yellow underleaf.

But lest the reader should tire of a prolonged march past, in which each deciduous tree follows another, we shall resort to the device of grouping, which has been used with such effect by Mr. Mongredien in his "Trees and Shrubs for English Plantations." The reds and yellows which predominate in an autumnal landscape suggest one such group, which has been partially anticipated; the towering and spiral tree-forms which stand out from such a landscape, and a group to which some of these belong, the trees that love the waterside, a second; and a third having been devoted to such as will endure town smoke, whatever space remains will of right belong to the Conifers. From the outlook we occupy, say on the last day of October, the eye comprehends within the lawn precincts the reddish-yellow of the Sumach, the less ruddy yellow tints of the common Medlar, the green-yellow of the Mulberry, and the burnished gold of the Norway Maple. Just beyond, a week ago, might have been seen the red foliage of the Bird Cherry, and at no great distance the rich crimson of the Pear leaf. Were fruit trees within our scope we might dilate on the lovely white blossom of the Medlar and Cherry in springtide, and the colour and grain of the Cherry wood when felled and converted. To these may be added the leafage of the Liquidamber just changing at the same season to a bright red from a golden amber, and the *Salisburia adiantifolia*, the leaves of which turn to a golden tint before they succumb to sharp frost. But as we are upon timber trees way must be made for the Maples; and first among them the presumably British Sycamore (*Acer Pseudo-platanus*), which puts on its autumnal brown-red, as Cowper notes, "ere autumn yet hath changed the woods," lest perhaps the change should go by default, so quick is it to part with its leaves, it may be owing to the density of its foliage, which adapts it for sheltering the sunny side of a dairy. A variegated Sycamore with white blotches on its leaf is a favourite and healthy-looking variety, and there are one or two others of more recent introduction. Against the fault of the Sycamore, that it does not carry height in proportion to its girth, may be urged the fact that it is a quick-growing tree of great durability, and in request with cabinet-makers, moulders, and turners. For a lighter carriage perhaps the Norway Maple (*A. platanoides*) may be preferred, a tree of first-rate growth, and as desirable for its uses as its ornament. Its early light green turns to brilliant yellow. It is lightsome in form and outline, and its timber exhibits the same beauty of fibre as the Bird's-eye Maple of America. The form of its

leaf is like that of the Western Plane, and it merits well the consideration of the planter. Mongredien recommends the variety called *Acer Pl. colchicum rubrum* for its dark red leaves; and it is worth while to try also for contrast the Sugar Maple (*A. saccharinum*), the smooth green leaf of which, with glaucous underleaf, changes in autumn to orange and crimson. This variety is the American Bird's-eye. Other species from North America are *A. eriocarpum* and *A. rubrum*, both of which are very susceptible of frost, and an Himalayan Maple of very recent introduction does not as yet encourage the hope of its becoming hardy in this country. It is curious that two of the Poplars from North America, *P. balsamifera* and *P. canadensis*, invert the order of colouring, exhibiting a soft yellow when their leaves expand in early spring, but changing with full maturity to a deep green with whitish-green underleaf.

But the Poplars are chief amongst our spiral and columnar tree forms. Who has not realised the character which a triplet of Poplars adds to a rural landscape, as they tower above the hedgerows and the lesser timber trees; or the semblance to a pinnacled cathedral put on by a group of these in the far distance, as it overtops the Oaks, and Elms, and Beeches that intervene? For ornament to the landscape, and upright, tapering, Cypress-like growth, there is nothing to beat the Lombardy Poplar (*P. fastigiata*). It is the tree "which wept amber on the banks of Po" in classic fable; and even where it does not, as at Great Tew, attain the height of 120 feet, its rapid growth enables it to contrast signally with trees of lower and spreading habit, and to "diversify," as Grigor expresses it, "the regularity of the sky-mark." In leaf it much resembles the later-foliaged Black Poplar, and its habit when swept bodily by the breeze, and when it

"like a feather waves from head to foot,"

is a sight to remember. Intermediate in habit between it and the Black is the monilifera or Black Italian, the fastest grower of the Poplars, which on stiffish soil or near running water attains to 100 feet, and makes planks for the largest buildings, that are neither apt to split nor to ignite. Distinct from these is the Abele, with a dark green upper and downy white under leaf, the hardiest variety of which is the common White Poplar (called *acerifolia*, from its deep-lobed leaf). The fault of the Grey Poplar is its tendency to realise the proverb, "Soon ripe, soon rotten." Full grown at forty years, and having a stem of 40 feet clear of branches, it is apt to take heart-rot at sixty. For its many associations the tall "light quivering Aspen" should be planted (which may best be done as a seedling); and, unlike most of its tribe, it is a native. Of elegant form and motion, it has a rich green foliage, which turns eventually to bright yellow. Its chief drawback is a tendency to innumerable suckers. Its slimmer allied species, called the Athenian Poplar, though it hails from the North American, not the Greek, Athens, is in some respects a more ornamental tree.

Next after the Poplars for upright and columnar growth comes the Irish Yew, a somewhat sombre fastigate evergreen of moderate height from Fermanagh; and among the Cypresses, Thujas, Biotas, and Junipers we shall meet with other trees of this habit and of more aspiring stature. A Pyrenean Oak, unnoticed earlier in our remarks, but hardy about London, whatever it be further north, the *Quercus fastigiata*, has a growth and shape by no means unlike the Lombardy Poplars. In its finest development the Occidental Plane might rank with this class, having an upright and quasi-fastigate growth (of from 70 to 100 feet), which distinguishes it from the Oriental Plane, a tree from its rounded form and bright flickering foliage is eminently suited for the lawn or pleasure ground. The Western Plane has this in common with the Lombardy and other Poplars, that it attains its greatest growth by the waterside. It is the same with the Willows and the tall American Birch (*Betula excelsa*), introduced about a century ago, and reaching in North America a stately well-branched growth of 80 feet.—(*Quarterly Review*.)

## DIOSPYROS KAKI.

I HAVE thought of trying this in a pot in an orchard house, but fear there are few who can speak from experience as to the probability of success. The three questions I want answered are—1st, Does the plant break readily from the old wood, so that the tree may be kept compact? 2nd, Does it fruit when small, say as readily as a Peach tree? 3rd, Is the fruit worth the trouble? This is, of course, a matter of taste. A person writing from Japan said that the fruits there were generally

bad, but that the Kaki was pleasant and good. I shall be glad if information can be given by anyone having experience of this fruit.—G. S.

### DOVER FLORAL AND FRUIT EXHIBITION.

THIS was held on the 29th inst. in the grounds of Dover Priory, and merited praise in all the divisions. The cut flowers, fruits, and vegetables were especially excellent. A fuller notice we hope to publish next week, but we must promptly particularise the success of one exhibitor, so well known and welcomed in our pages—the Rev. H. Honeywood Dombrain. He had awarded to him the chief prize and a second for Gladioluses, and it is enhanced by the fact that he had as a competitor Mr. Baker, whose collection is so vastly larger in numbers than Mr. Dombrain's. The Gladioluses in his first-prize stand were *Blanche*, *Murillo*, *Norma*, *Adolphe Brogniart*, *Lady Bridport*, *Sir Redmond Barry*, *Marie Stuart*, *Rossini*, *Meyerbeer*, *Madame Desportes*, *Genievra*, and *Leda*.

We would observe that the excellence of Mr. Dombrain's flowers were done justice to by their superior arrangement and the style in which each spike was displayed. This was rendered more striking by some of the competing collections appearing distasteful by the careless way in which the spikes were placed in the stands.—G.

### NOTES AND GLEANINGS.

WE have received the schedule of the INTERNATIONAL HORTICULTURAL EXHIBITION which is to be held at Dundee on the 7th, 8th, and 9th of September. The schedule is very comprehensive, numbering 206 classes—namely, 64 for fruit, 57 for plants, 36 for cut flowers, 10 for table decorations, &c., and 39 for vegetables. The prizes offered are liberal, amounting in the aggregate to upwards of £1000, besides gold and silver cups and medals. For twenty sorts of fruit, prizes of £15, £15, and £10 are offered; a gold cup of the value of £20 being given by the Earl of Strathmore to the winner of the first prize. For eight varieties of Grapes a gold medal is added to the first prize of £15, the second prize being £12, and third prize £7. For twelve stove and greenhouse plants prizes of £20, £15, and £10 are offered, a gold medal being provided for the winner of the first prize; a gold medal is also offered in the class for nine stove and greenhouse plants. Messrs. Dickson & Turnbull give a silver medal to the winner in the class for six greenhouse plants in flower, and Messrs. Robertson & Galloway a similar medal for twelve spikes of *Gladioli*. A special committee is appointed to take charge of the exhibits, and every facility is offered to intending exhibitors. Arrangements have been made with the railway companies to carry plants, &c., at a single fare for the double journey, such plants &c., not changing ownership; and the Caledonian, North British, Glasgow and South-Western, and Highland Railway Companies have agreed to carry all passengers going to the Exhibition the double journey for a single fare—the tickets to be available from Wednesday, September 6th, to Monday, September 11th, on condition that the railway tickets are stamped at the Show. A large and successful gathering is anticipated.

REV. W. F. RADCLIFFE writes as follows on PEA PROTECTION:—"Before sowing Peas dip them into benzoline and immediately sow them. Mice will not touch them before they come up, and sparrows will not damage them after they are up. Aloe dissolved in water is also a good protection. Put the Peas into the solution the night before sowing. The sorts I use, and they are good, are *Ringleader*, *Princess Royal*, and *British Queen*. Gardeners and amateurs love, like *Athenians*, some new thing. The prices charged for new Peas are enormous: 7s. 6d. for a quarter of a pint amounts to £96 per bushel of thirty-two quarts!"

THE second show of the season of the BURTON-ON-TRENT HORTICULTURAL SOCIETY, which was held on the 23rd inst., was very successful. There was a good show of stove and greenhouse plants, Ferns, Roses, Stocks, Hollyhocks, Dahlias, bouquets, Marigolds, Phloxes, and Verbenas. Among the fruits there were some fine black and white Grapes, Cherries, Apricots, and Apples. The best specimens of vegetables might be found among the French Beans, Celery, Carrots, and Potatoes. Mr. W. Bennett, gardener to Mr. M. T. Bass, M.P., Rangemore, was first for stove plants, Begonias, Ferns, collection of miscellaneous plants, table decorations, cut flowers, collection of fruit, Pine, Black Hamburg Grapes, black any other sort, Peaches, Nectarines, Cherries, Black Currants, Scarlet Beans, French ditto, Cauliflowers, Carrots, white Celery, and culinary herbs. Other successful exhibitors were

Mr. Tobin, gardener to Mr. F. Gretton, Bladon House; Mr. E. Hollis, gardener to Mr. J. T. Poyser, Stapenhill; Mr. G. Gough, Little Malvern; Mr. G. Chitty, gardener to Mr. Guy Nadin; Mr. H. Draycott, Leicester; Mr. F. Wood, Derby; Mr. W. Cunningham, The Forge; Mr. G. Bentley, gardener to Mr. R. S. Tomlinson; Mr. T. Wilson, gardener to Mr. J. Nadin, Ashby Road; Messrs. Perkins & Sons, Coventry; Capt. Webb, Lichfield; E. D. Salt, Esq., Newton; Mr. R. Spencer, gardener to Mr. R. Ratcliff; Mr. H. Frettingham, Beeston, &c.

By the kind permission of Lord Eversley the gardens at HECKFIELD PLACE, Winchfield, may be inspected by the public on the 4th, 11th, and 18th of September; and from the well-known reputation of Mr. Wildsmith both as a flower-garden and fruit cultivator a treat of a high order may be anticipated by those who can avail themselves of the privilege which is now again offered by the noble owner of these renowned gardens. Applications for tickets of admission should be made to Mr. Wildsmith.

WE recently noticed in the flower garden at Wimbledon House some fine plants of *CHAMEPUCE DIACANTHA*, which are noticeable as having been raised from seed sown last autumn in the open border, the seedlings having had no other protection during the winter than that afforded them by a common hand-light. That, Mr. Ollerhead states, is the best mode of raising a supply of these distinct plants; and now that he has shown us how easily they may be produced they will probably be found in more gardens in the future than has hitherto been the case. The seed may be sown in light soil in September, and the plants may remain with the slight protection alluded to until they are large enough for removal in the spring. *C. cassabona* may be increased in the same simple manner.

A CORRESPONDENT writes thus on the subject of TOMATOES PREVENTING WASPS FROM ENTERING VINERIES:—"Those who find Tomatoes a deterrent of wasps have either different kinds of wasps or different sorts of Tomatoes to deal with than those coming under my experience. In the vinery in my charge Tomatoes are largely grown, and they are no more effectual in frightening away the wasps from the Grapes than is a hat stuck on a stick in driving away the blackbirds from the Strawberries. If any gardener has a Tomato that will really keep wasps out of a vinery, I shall take it as a great favour if he will send me a pinch of seed through the Editors of the *Journal of Horticulture*, and for which I will gladly pay postage."

CONSIDERABLE attention having been given recently to the cultivation of *HEVEA BRASILIENSE*, which yields the best rubber or caoutchouc, imported from Para in Brazil for introduction to Ceylon and other tropical countries, it will doubtless be of interest to give particulars of the first large consignment. The seeds were received at Kew in June of the present year, and just at the expiration of eight weeks thirty-eight Wardian cases, each containing fifty plants, were sent to Ceylon. Other cases have been sent to Singapore, and about 2600 plants will altogether be distributed. The seeds live but a short time, and in the present importation scarcely 4 per cent. were alive when received. The number was about seventy thousand, and as each is as large as an average Gooseberry the space occupied was considerable. The plants grow with great rapidity, as must be imagined from the time within which the seeds were received and the plants sent away—indeed the cases had to be of such a height that would allow the plants room for growth during their confinement. The growth is not continuous from the first; after producing the first few leaves there is a few days' cessation, then when the stem is so far firm another rapid growth is commenced.

WE have received from Mr. W. LOVEL, Weaverthorpe, York, a POST BOX containing Strawberry plants and cut flowers, which arrived in a perfectly fresh state. The box is worthy of notice. It is made of stout cardboard, ingeniously folded and pinned at the ends. Mr. Lovel states that these boxes can be made by a boy at the rate of eight or ten per hour, and their cost is not more than a halfpenny to a penny each, according to size. Any person can make them after seeing a pattern. They require no stitching and no paste, and would be much used if generally known.

THE "CORRESPONDENCE BOTANIQUE" for 1876 has just been published. It is a directory of all the botanic gardens, professors, curators, and distinguished botanists throughout the world, and is one of the most valuable publications of the

day. When we say it is produced under the direction of M. Ed. Morren of Liège we have a guarantee that the information it contains is reliable.

— **THE LAVENDER HARVEST.**—The recent heat has had the effect of improving greatly the Lavender harvest. It may not be generally known that we have such an industry in England. A correspondent writes recommending those who have seen and admired the flower farms of Provence to pay a visit some warm summer like the present, at the end of July or beginning of August, to the Lavender fields, planted something over half a century ago outside the town of Hitchin, where, the correspondent believes, the comparison of sweet scents will be in favour of our Hertfordshire gardens.

— **M. DE SAPORTA** has recently communicated to the Central Horticultural Society of France a note on the minimum temperature which can be borne by *EUCALYPTUS GLOBULUS* and other plants in the south of France. M. de Saporta remarks that, during the winter of 1870, the temperature at Hyères sank to 8° C. below freezing point (25° Fahr., or 17° of frost), when the Lemon was killed to within 3 feet of the ground, the Orange half-way down, while the *Eucalyptus globulus* only suffered in some of its smaller branches. *Buonapartea* sp., *Dracæna indivisa*, *Chamærops excelsa*, *Sabal umbraculifera*, and *Cocos australis* remained unhurt; and *Corypha australis* was much injured, but subsequently recovered. The Date Palm suffered but little, though the Oleander was killed to the ground. All the plants just mentioned were planted in the open, and received no protection. *Chamærops excelsa* in the Basses Alpes withstood a cold of 16° C. below freezing point (6° Fahr., or 26° of frost), with only a little litter around the stem. *Eucalyptus globulus* does well in slightly moist or even in dry soils, but not in those which are constantly moist; while *Sabal Adansonii*, which also resisted 8° C. below freezing point, does well in marshy places.

— **BORAX**, says the *English Mechanic*, is said to have yielded good results in an investigation into its merits as an antiseptic. A solution destroys the spores of parasitic plants, as the minute fungi on Grapes, &c., and also has a remarkable power of arresting the lower forms of animal life. A saturated solution of boracic acid, with a small quantity of borax, salt, and saltpetre, makes a "brine" in which fresh meat is treated with so much success that it can be preserved untainted even in the hottest parts of the earth.

— We are informed that not less than £10,000 worth of FLOWERS were sold in Paris on the 25th inst. in preparation for the fête of St. Louis, which took place on the day following.

— A THIRD edition of Mr. Francis George Heath's work "THE FERN PARADISE," which we favourably reviewed a short time since, is we understand in the press.

## OUR BORDER FLOWERS—GLOBE THISTLE.

To those who are interested in border flowers the present is a time of year when collections should be inspected, notes taken, and selections made, for now many of our summer border flowers are in beauty, and the autumn-flowering plants are following in their wake.

From many parts of the world we have had imported several different kinds of Globe Thistles, but how seldom do we meet with any number of them in cultivation. Some are ready to say of them that they are vulgar-looking plants, but look a little closer and examine their structure before thus deciding. Under some circumstances we meet with two or three kinds, principally in some old-established nursery, where they used to have care bestowed upon them and are now looked on as heir-looms. As individual plants for out-of-the-way corners, open spaces in shrubberies, or wilderness walks, no plants are better adapted than the Globe Thistles; but to see them to advantage they should be grown in groups, and they will secure a prominent place in the enthusiastic cultivator's estimation.

*Echinops sphaerocephalus*, introduced from Austria in 1596, should be found in all shrubby borders. When well grown it is a noble plant, and when established it only requires to be left alone and will last for many years. *E. Ritro* and *E. spinosus* are the kinds most commonly met with. Others there are that ought to be more frequently seen, some of them having a woolly appearance, which adds a charm to their noble stature. These might be introduced into subtropical gardening with good effect. They do not object to partial shade, but succeed well in full exposure. Loam and grit broken up to the depth of 2 feet will afford them a good medium for their development.

They should have efficient drainage, and water as required. They remain long in bloom, and are useful for exhibition. The taller kinds require staking to guard them against wind. Old stools are the better for having the shoots thinned out when growth has commenced. They are increased by division in autumn or spring—the latter is the best time; the operation requires care in the performance of it.—*VERITAS*.

## NOTES ON VILLA AND SUBURBAN GARDENING.

### KITCHEN GARDEN.

SUCH dry weather as we have had, and the effect it has had upon vegetables generally, will, or ought to, induce people to house their produce as soon as they can do so. As far as my experience goes, it is too late to expect any benefit from rain if it comes to such crops as Onions, Carrots, Potatoes, Salsafy, Scorzonera, Beetroot, &c., because the continuance of dry weather has caused a sort of premature ripening, which ought to be a guide to growers to take up their crops and store them. We often witness that after root crops have nearly completed their growth and rain comes on, they begin to grow again. For instance, the Potato is one of the first to do that, and it is well to bear in mind the injury which follows. When Carrots and the other root crops I have mentioned begin to throw out white roots their quality is consequently very much deteriorated.

I have never found that root crops increase in size after this time in such a season as the present. The Onion is one of those roots that if it is not taken up now will not begin to root so soon as many other crops; but it takes up moisture to such an extent that it neither keeps well in the ground nor out of it, for if put into ever so dry a place the bulbs will not keep; therefore it is not out of place at this season of maturation of crops in general to remind cultivators that there is as much or more judgment required to know when a crop should be taken up and to keep it afterwards as there is in the sowing and growing of it. If Onions are pulled up in dry weather they may be left on the ground for some time; but should there be signs of wet they should be taken in when dry and laid out on a floor with a dry bottom until they are pretty well "harvested," and then to be strung upon sticks according to size and the number likely to be used at a time, and suspended anywhere where they can be kept dry.

When the ground is cleared the succeeding crop ought to be considered. Let the Onion ground be well manured and trenched in preparation for planting with Cabbages, which may be planted out at any favourable time.

With regard to the crops of Broccoli and greens of different kinds, some would say that they ought to be earthed-up when they arrive at a suitable size. Now, in such seasons as the present I do not agree with earthing too soon, for nearly all know that when plants are earthed-up that it is considered a finish to them, and they are left to themselves; whereas I consider that, though earthing of such tall-growing crops secures them from injury by the wind, they are not benefited by earthing if the operation is done too soon. For instance, the soil can be worked and kept clean much better; but if rain comes now, which we very much want, the plants would receive more benefit from it than if they were earthed; and if we take the Brussels Sprouts for example, which, according to the season, are not so far advanced as they are in more favourable years, they have much growth yet to make, and they will do it better by non-earthing than by earthing, but by all means earth them afterwards.

Scarlet Runners are now cropping well, but had it not been for watering and mulching there would not have been half a crop. Not having any rain for many weeks the system of watering is all-important; but if it is done without mulching it cannot have had such a beneficial effect. It is a good plan before mulching to stir the ground well and then put the manure on, which fixes itself on the surface of the soil, and, as it were, draws the roots to the surface, where they can receive the benefit of moisture; but if the soil is watered without this surface-dressing, and the sun plays upon it with such effect, and it becomes caked so that air cannot enter, the crop does not do so well in consequence. Mulching ought to be more generally adopted in the summer cultivation of nearly all crops.—*THOMAS RECORD*.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

THE warm showers have caused weeds to start freely on ground that had been prepared for Coleworts, Broccoli, &c., and it has been necessary to run the Dutch hoe through between the rows. The ground is now in excellent order for sowing or planting. Perhaps other districts not far removed from us have not had so much rain, as all that has fallen here has been in the form of thunder showers, which are usually local. We had last week on

one day three-quarters of an inch of rain fall in the dinner hour, and three miles distant not a drop fell during the same day. Again, the severe thunder storm accompanied by hailstones as large as walnuts that occurred a few weeks since was also confined to a limited radius: it did much damage at Tottenham, Lea Bridge, and Stratford, coming within about two miles of Ilford, but all we had the same day was a gentle shower of rain.

Turnips may yet be sown, and a sowing may also be made of Lettuce and Radish seeds. A plantation of Celery may also be made at this time. Strong plants may be put out in beds—say from three to six rows. A much larger quantity can be obtained from a limited space than if the plants are put out in single rows. As opportunity offers we earth-up all crops requiring it. Early Celery should be earthed, carefully removing all suckers that start from the base of the plants. The leaves ought either to be lightly tied together with a strip of matting, or fastened together with paper. Exceedingly fine Celery is grown at Preston and in the neighbourhood of that town, much of it for exhibition. The growers blanch it in two ways, besides the usual one of earthing up—namely, by fastening the leaves together and covering the stalks to a length of a foot or more with brown paper wrapped round the plants, or else a 3-inch drain tile is placed over each plant. Peat has also been recommended for earthing-up Celery, and the heads turn out of this clean and white.

It is difficult to know what is best to be done with Potatoes this season. Some say, Take the crop up, and others recommend to leave the Potatoes in the ground. With us early Kidneys were a good crop, and the haulm decayed before the ground was dry, and the crop was taken up. Next in succession came what is called here the Early Shaw. At the time the tubers had grown to nearly the full size they were checked by drought, the intense heat causing the Potatoes to sprout. We saved some of them, and they are keeping well. Walker's Regents and Dalmahoyes have suffered very much from the drought; the haulm was in a very drooping condition, and the tubers had quite stopped growing before they were half their usual size, and they also began to sprout. After the rain the tops started to grow afresh, and the young Potatoes are also sending shoots through the ground. Whole fields may be seen in this unfortunate condition.

#### ORCHARD HOUSE.

The midseason sorts of Peaches and Nectarines are now ripe; the earliest sorts are over. We used to be at some pains to fasten a piece of close netting under each fruit, and as the fruit dropped we would gather it every day. This plan, however, is not so good as that of carefully going over the trees and gathering all the fruit that parts easily from the branches. A little experience is necessary to detect which fruits are ready for gathering. We have flat-bottomed baskets with a sheet of wadding in the bottom, and over that a sheet of soft paper. The fruit is carefully placed in the bottom of the basket and carried at once to a cool room, where it will keep several days longer and be of better quality than that allowed to fall from the trees. We have very good fruit of Dese Tardive Peach; it is later than Grosse Mignonne and Bellegarde, and ought to be extensively cultivated. We first saw this sort on the back wall of a late Peach house with Mr. Spivey of Hallingbury House near Bishop Stortford, Essex. He had fruit about 12 inches in circumference and of excellent quality. Exquisite is a very good flavoured yellow-fleshed Peach of the largest size: it is such a distinct variety, and withal so valuable for its lateness, that it ought also to be grown in a select collection. The Stanwick Elruge Nectarine during this and last season has been very fine. It is a highly coloured variety with rather more of the Elruge than Stanwick in its composition, as it is not a clingstone, but the flesh is firmer than the Elruge and more highly coloured.

#### GREENHOUSE AND CONSERVATORY.

It is a great advantage to Azaleas and many other species of New Holland plants to be placed out of doors even for a few weeks at this time. We had a plant of *Hedera tulipifera* that had been persistently attacked by mildew, and the young growths did not seem to ripen well. In a sunny position out of doors the plant has much improved, and the mildew has not spread on it. Ornamental-foliaged plants, such as *Phormium Colensoi*, *P. variegatum*, *Yucca aloifolia variegata*, *Y. quadricolor*, and others of this section bring out the variegation much more distinct and brighter out of doors.

Plants that are likely to be blown over by the wind should be fixed in position to avoid this calamity. Our plants are placed upon bricks in order that the air may circulate underneath the pots. Two bricks are sufficient for a pot up to 15 inches in diameter. The bricks are laid on the ground parallel to each other and 3 inches or more apart; three stout sticks are driven into the ground, and to them the pots are fastened. Azaleas and hardwooded plants generally may be trained into shape as opportunity offers. The new tying material raffia has come much into use for tying purposes, and it is the best to use for any softwooded plants of an herbaceous nature requiring to be cut down a few weeks or months after the ties have been made; but for all hardwooded plants strong black linen thread should

be used. This lasts much longer than any description of bast or matting.

In training plants some thought ought to be given to the natural habit of them, and the teachings of Nature ought to be followed closely. How seldom, for instance, do we see Azaleas trained in their own natural habit—that is, in the form of a bush more or less irregular; they are either pyramids with every shoot that projects an inch or two from the regular surface tied closely down, so that the plant when in flower presents a cone of colour red, white, purple, or mottled. Equally contrary to natural teaching are the umbrella-trained plants, with a smooth stem a yard high for a handle, and the plant trained to a framework of wire in imitation of an umbrella. Many of the hardwooded plants at exhibitions in the metropolis are too severely trained, and if the same plants were a little irregular in outline they would stand higher in the estimation of the judges, and the general public would have a better idea of the habits of the plants.

Stage Pelargoniums that were cut down a few weeks ago are now starting freely out of doors. When the young shoots have grown an inch the plants will be turned out of the pots, a considerable portion of soil shaken from the roots, and the plants be repotted in smaller pots. Cuttings that were put in early in July, when they show by their making new growth that they are rooted, should be repotted into small pots, one plant in a pot. They should remain in these small pots until February or March and then be repotted into 5-inch pots, when each plant if well managed will produce a dozen trusses of bloom.

Chrysanthemums have made healthy growth this year. They seem to like a hot season with plenty of water both at the roots and over the leaves; the plants must also be quite free from insect pests; all the growths must be trained into shape now, as in a few weeks they will be too hard to bend in any direction without snapping. Plants that are grown for the quality of their flowers also require attention, and all the late-flowering sorts should have the buds saved: of these may be named Princess of Wales, Venus, Lady Slade, and others. What cultivators mean by "setting the buds" is this—about a month or six weeks ago a single stem branched into three separate growths, on each of these will now be found a flower-bud and three leafy growths. If these three leafy growths are not stopped the buds will perish, but if they are pinched off close to the flower-buds these will develop themselves into the large flowers that are seen at exhibitions in November. Each plant will carry about three flowers, one only being allowed on each branch. After the buds are formed and have begun to swell they are not unfrequently attacked by a maggot very much resembling the Rose maggot. The best way is to pick them off by hand. If aphides still infest the growing shoots the insects must be destroyed by dusting them with snuff or tobacco powder. Red spider will not do any harm if the plants have been well syringed.

We have potted Cinerarias into their flowering pots, using 8-inch pots and moderately rich open soil. The Cineraria does best when the pots are placed on a damp bottom; the leaves are kept free from green fly and thrips by fumigating. Cyclamens have also been shaken out of their pots and repotted, likewise *Primula amona* of sorts. Roses for early forcing have also been potted into their flowering pots; the plants have been placed where they are slightly sheltered from the sun and from south-west winds.—J. DOUGLAS.

#### TRADE CATALOGUES RECEIVED.

Charles Turner, The Royal Nurseries, Slough.—*Catalogue of Dutch and other Bulbous Flower Roots, List of Strawberries, &c.*

Francois & Arthur Dickson & Sons, 106, Eastgate Street, Chester.—*Catalogue of Dutch and other Flower Roots.*

Messrs. James Carter & Co., 237, High Holborn, London.—*Illustrated Catalogue of Dutch Flower Roots, Roses, Plants, and Garden Requisites.*

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

THORNTON HEATH. September 1st and 2nd. Mr. W. Raines, 10, St. John's Villas, Bensham Manor Road, Thornton Heath, Hon. Sec.

MONTROSE. September 1st and 2nd. Mr. Alex. Burnett, 2, High Street, Sec.

STAMFORD. September 7th. Entries close September 2nd. Address the Hon. Secs., Stamford.

DUNDEE (International). September 7th, 8th, and 9th. Mr. W. B. McKelvie, 26, Euclid Crescent, Sec.

GLASGOW. September 12th and 13th. Mr. F. Gilb. Doughall, 167, Canning Street, Sec.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY. September 13th.

KILMARNOCK. September 14th. Mr. M. Smith, 11, King Street, Sec.

IPSWICH. September 17th. Sec., Mr. W. B. Jeffries, Henley Road, Ipswich.

NORTHAMPTON (Chrysanthemums). November 14th and 15th. Mr. W. Gutteridge, 51, Denmark Road, Northampton, Sec.

LOUGHBOROUGH (Chrysanthemums and Fruit). November 21st. Mr. John West, Chapman Street, Loughborough, Sec.

## TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

**BOOKS (A Constant Reader).**—For reference on gardening matters the "Cottage Gardeners' Dictionary" will suit you, price 6s. 6d., post free 7s. 2d.

**REMOVING TURF (Daisy).**—You cannot legally remove it.

**PLUMBAGO EATEN BY INSECTS (Mrs. M.).**—Syringe the plant occasionally with a solution of soft soap of a strength of 2 to 3 ozs. per gallon, adding a pint of tobacco water to each gallon of the soapy water.

**ROSES IN POTS (Oreonia).**—You will find the cultivation of Roses in pots fully and ably described in the present number by Mr. Moorman, who is one of the most successful of amateur exhibitors. You cannot do better than follow Mr. Moorman's instructions.

**SEEDLINGS OF PHLOX DECURSA (C. Barke).**—The flowers sent are very good, the colours being varied and the pipes generally being well formed. We cannot aid you in their disposal beyond advising you to submit good trusses of them to a florist dealing in hardy flowers.

**FUCSIAS UNHEALTHY (E. M. M.).**—Your plants are devoured with thrips. Dissolve 2 ozs. of soft soap in a gallon of water, and to this add a pint of strong tobacco water, and with this mixture syringe your plants every ten days. If the plants are small you had better dip them in the solution. If they are large lay them on their sides on a mat and drench them thoroughly. The mixture should be used at a temperature of 100° to 120°.

**SEEDLING CARNATIONS (W. S. Bath).**—Pot-off your seedlings in small pots, using a compost of two-thirds of medium turfy loam and one-third of leaf soil, adding also bruised charcoal and silver sand freely. The pots must be well drained and the soil carefully examined for wireworms. The plants may be placed near the glass in an unheated frame, keeping close until they are established, then admitting air freely, but guarding against cold currents, and especially rain. They must be watered carefully, particularly in dull weather, or the plants may become affected with the spot or rust, which is more injurious to them than cold. They may be wintered in the same frame, plunging the pots in ashes and covering the lights in very severe weather.

**INJURED ROSE LEAVES (J. P.).**—It is the black mildew, generally speaking the result of dryness at the root. The mildew attacks the leaves after injury is caused from defective sap action, and hot dry weather injures the breathing pores on the upper surface of the leaf, causing an exudation of sap, on which the fungus grows. Roses against walls and standards with long stems which are exposed to the action of the sun, and consequently much dried up in such weather as we have had between July 18th and August 1st, and again between August 7th and the 23rd, are especially liable to such attacks. Good farmyard manure in winter and liquid manure in the hot summer months are the best remedies, or rather preventives. Give liberal supplies of water at intervals, not dribbles constantly.

**HYACINTHUS CANDICANS (G.).**—We believe it was imported from the Cape of Good Hope, and first exhibited by Mr. Wilson Saunders. Botanists were long in debate whether to call it a Hyacinth or a Snowdrop. The first was adopted, but several good botanists doubt the correctness of the decision. Mr. G. F. Wilson, having saved the seed of this bulb, has grown many, half a dozen bulbs in a pot, in an orchard house. They grow between 4 and 5 feet high, and are very showy. Planted out in a cool border they produce strong plants and endure the winter perfectly. This answer has been accidentally delayed.

**RASPBERRIES, CURRANTS, AND GOOSEBERRIES INFESTED WITH CATERPILLARS (A. Hustable).**—The leaves of the Raspberry have been eaten by the Raspberry-bud grub (*Tinea corticella*), which is injurious to the buds in spring by consuming their interior, the presence of the grub being detected by the withered appearance of the flower buds. It is the larva which feed upon the leaves usually in early August, continuing up to winter. They, so far as we know, are only to be destroyed by pinching. The Gooseberry and Currant caterpillar may be destroyed by sprinkling the parts infested with white hellebore, 1 oz. to a gallon of water, applying with a whitewash or painter's dust brush, sprinkling the bushes by means of the brush dipped in the hellebore water. It should be used fresh. We have no caterpillars, which we attribute to the presence of small birds, which are the most effectual grub and insect destroyers.

**HAUTOIS STRAWBERRY CULTURE (Flora).**—Make a fresh plantation in rich deep soil, taking well-rooted runners of the current year, planting them in rows 2 feet apart, and 18 inches from plant to plant. Next season do not remove the runners, but allow them to root between the rows, and after the crop is gathered and the runners well rooted out away the old plants, leaving the runners between the rows, keeping them to a row about a foot wide, manuring the space in autumn where the old plants have been growing. Alpine Strawberries may be planted now, but better plants are had from seed sown in gentle heat in spring, and the seedlings hardened off and planted out when ready. They will fruit in summer up to autumn; or seed sown now and the plants wintered in a frame, planting them out in spring, will give you earlier-fruited plants.

**POT VINES OVER HOT-WATER PIPES (Rus).**—Place the pots upon the hot-water pipes, and feed the roots liberally by surface dressings of rich compost and liquid-manure waterings. The roots wandering from the pots cannot be so readily fed as when they are confined to the pots. Our correspondent mentions "as a good Tea Rose Madame de St. Joseph, an old Rose, but with me quite a perpetual."

**MANURING A NEGLECTED GARDEN (G. R.).**—There is no concentrated manure which can entirely supersede the use of ordinary manures on exhausted soils, and never will be, for the simple reason that the principal fertilising properties of manure are contained in the gases given off during

decomposition. In your soil which has been cropped for seven years without manuring there is a lack of vegetable matter, and nothing but vegetable matter can thoroughly restore fertility. If the manure must be taken through the dwelling-house something should be sought for less objectionable than stable manure. Cocoa-fibre refuse is very good, and so is malt dust, while a slight sprinkling of artificial manure would do no harm. Of course every leaf which is grown in the garden and not required for other purposes should be restored to the soil. Flower beds have done well for several years manured only with the plants grown on them.

**PRUNING GOOSEBERRY AND CURRANT BUSHES (Idem).**—Bushes 6 feet through and touching each other may, if the growth is crowded, be thinned so as to admit light and air; and so long as there is not more than a third of the foliage removed they may be cut at once into any desired shape, bearing in mind that the fruit of Gooseberries and black Currants will be mostly produced on the young wood, and that of red and white Currants on spurs and wood which is two years old. You cannot grow a crop of vegetables under the bushes without injuring them, as in digging you would cut the roots, which extend at least as far as the branches, besides impoverishing the soil. Stuckers of Raspberries coming up a distance from the stools should be cut off if not required for transplanting.

**LARGE SCARLET GERANIUMS (J. A. M.).**—The plants should not be pruned back in the autumn. They should be potted every year until they are established in pots of the size required, and then a good portion of the soil should be removed annually in spring, replacing it with a fresh rich compost of loam and decayed manure. When the pots are filled with roots copious supplies of water must be given, using manure water twice a week during the season of growth. Large plants are quickly established by planting them out for a year or two, potting them in the autumn and pruning away the gross sappy growths, permitting the short-jointed shoots to remain unshortened.

**NAMES OF FRUITS (Henderson).**—The Fig was smashed and quite unrecognisable. (*Connaught Subscriber*).—1 and 2, Corse's Nota Bene; 3, Belgian Purple.

**NAMES OF PLANTS (G. R. B.).**—It is a *Stapelia*, but we cannot say what the species is from so fragmentary a specimen. (*W. W.*).—1, *Bignonia grandiflora*; 2, *Rhus Cotinus*; 3, *Biota aurea*; 4, *Picea Nordmanniana*; 5, *Polystichum aculeatum* var.; 7, *Hibiscus syriacus*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

## DISQUALIFICATIONS.—PART 2.

ON July the 13th we wrote on this subject, and then alluded to the importance of the reason of the disqualification being always declared. We want to say a few more words on the subject this week, for since then the topic has been much ventilated and more disqualifications have taken place. One of our contemporaries went into the subject last week, and we agree with a great deal there written. It advocates that not only when an exhibitor has a bird disqualified he should forfeit the whole of his prizes won with other pens, but even proposes that anyone once disqualified should never be allowed to exhibit at the show again. This sounds all very good and proper, and we quite believe that very likely much improper work might be so stopped. But before anything very definite is arranged we think exhibitors too, as well as committees, should have their say. We have not the remotest intention of supporting a disqualified exhibitor if honestly disqualified, but we do say once more that the reason of the disqualification should be made known to all, that opportunity should be given to the owner of any doubtful bird to clear away the suspicion that the judge has not been very careful in what he has done. By enforcing such very strict rules about disqualifications we can see many difficulties. We will give one or two examples.

At a late show an exhibitor was disqualified for having a Spanish cock in the pen which had had its comb cut. Now this exhibitor had bought the bird of another exhibitor, having claimed it at the catalogue price at a show. When bought the bird's comb was in precisely the same state as when it was exhibited afterwards. Now we ask, Was this exhibitor to forfeit all the prize money and be debarred from ever exhibiting again at that show because of someone else's work? or would the matter be investigated and the real vendor and operator become the culprit? But surely then that party would say, "I never asked the purchaser in question to buy, and the bird was bought with its failings and merits, and so why should I be prevented from ever exhibiting again at this show?" Or would the disqualification under these circumstances fall through altogether, and the exhibitor have the prize money save of the one disqualified pen? If the latter, surely a great opportunity could be given to unprincipled people to palm off their own work on others. Or again, another instance: when a judge disqualifies a bird wrongly is the exhibitor to bear the blame for, perhaps, some crochets of an adjudicator? We remember once seeing a pair of Cochins belonging to one of our oldest and largest exhibitors at a summer show in the deepest moult. Breasts and thighs and backs were in many places bare, and their tail feathers were also entirely gone. This pen was disqualified because of the absence of the tails. Every exhibitor who understood a Cochins' points said that the judge had made a mistake, and that the tail feathers with the other feathers on the bird's backs and thighs had moulted out; for even had the bird desired trimming, no one in their senses, especially this Cochins exhibitor of a score of years' fame, would have bodily plucked

out the tails. Now this was one of the greatest of our agricultural shows, and was this exhibitor to be prevented from ever again showing there because of this mistake? Only last week a Cochon cock was disqualified for a cut comb, which belonged to one of our great exhibitors. We could prove without any doubt that the bird was in the same condition when it passed into that exhibitor's hands, yet is he to bear the blame, especially when he was ignorant of the fact? and as the vendor of the bird has since retired from the fancy, what would be done in such a case? We maintain that much as the poultry world would be benefited by some well-laid-down rules about disqualifying, yet we should be careful how we set about them. In these days, when birds often change hands two or three times in a season, it is very difficult to prove just where or by whom a bird has been plucked, cut, or doctored. Cases of staining and painting would be easier to trace. But even here many an exhibitor might be unfairly used and turned out of the list of some show unjustly, for over and over again birds are sold even to clever exhibitors which have been "done-up" in some way, yet without detection; and over and over again birds are bought in the exhibition pen at one show because they are apparently perfect, and yet have been well "set in order" before leaving home.

We hear that two or three of our judges have determined to make a great set against trimming and cutting. We are glad to hear it, and we will back them up in every way provided the cases are genuine and honestly proved, and we hope that those judges will not forget that Hamburgs' combs are much more chopped about than even the combs of Cochons or Spanish are. Before a clean sweep can be made of "improving" poultry fanciers, we are certain that some definite plan must be generally agreed upon about what is allowed and what is not; whether Spanish, Black Polands, Game, and Hamburgs may be beautified in one part of their bodies but not in others, and if so, to what extent this may go. We really believe that if the judges would have a meeting and throw aside for the occasion any petty jealousies of each other, they might come to some very satisfactory arrangement which would please most exhibitors. We would recommend their calling in some of the best authorities and breeders as well, and so try to put things on a better footing; for as matters are now there will always be disputes and troubles, as a bird may very likely win the cup under one judge and be disqualified under another.

As regards enforcing the penalties which our contemporary advocates, much as we agree with it that something wants doing, and that, too, at once, we hardly think that those it proposes will be as pleasing even to honest exhibitors as one might imagine; for an exhibitor who did not breed all his or her stock would very probably fear some such misfortune arising as it did to the owner of the Cochon hens a few months ago, to the owner of the Spanish cock a few weeks ago, to the owner of the Cochon cock a few days ago, because a disqualification will tend to damage their reputation even though they may be able to prove themselves innocent; for it is the fact of the thing which remains in the eyes of the world, and it is often impossible to remove the opinion that somehow or other the exhibitor has tried to mislead the judge and cheat other exhibitors. Of course some may find out that a bird has been "done up" after it comes into their possession, although they did not know it at the time of purchase, and then they never need show the specimen; but there are so many young and less skilled exhibitors, who would never find out anything wrong until the judge had discovered it and the mischief was done. We shall say no more, but look hopefully forward for the introduction of some decisive yet reasonable measures being adopted to remedy the evils of which so many have cause to complain.—W.

### POULTRY AND BIRD NEWS.

We understand that at Bath the Canaries and other birds are to be exhibited as before in the summer alcoves. Charming as are these recesses for the birds, we fancy they are somewhat chilly and cold. By September the evenings are often very cool and damp, and we have heard of many birds dying from the unwonted exposure. We should recommend all exhibitors consequently to see that their cages have a piece of stout muslin or some such stuff round them to keep out the draughts to some extent.

The Malmesbury prize money has been paid, and this within a week of the close of the Exhibition. Such quick settlements well deserve notice.

We understand that Mrs. Dring disposed of one of the pens of Crêves of her late husband's to Mrs. Webb of Stockingford Vicarage in May last. This was of course previous to selling the whole of the remainder to Mr. Burrell.

We are sorry to notice that the Aylesbury schedule has been altered without much improvement. A few extra classes have been added, but the prizes have been all reduced one-fourth. The variety Bantam class has been entirely cut out, and only

two prizes are promised in the Variety class, where Turkeys still have to take refuge. We doubt very much if the Committee will find the alterations have been for their good. The Leghorn Club guarantee the prizes in the Leghorn classes. The management at this Show is always extremely good, and the place of exhibition admirable in every way.

We have heard from Portsmouth in reference to the non-payment of the prizes, and hear that "the Committee are making all the efforts in their power to make wrong right, which they trust with a little indulgence from the exhibitors will enable them to act honourably to all." So far so good. Now, the question arises as to the shape the desired "indulgence" will take. Will it be in only part payment of the prizes, or is it only more time that is required? If the latter, we should be glad to hear how the money is proposed to be made up in the extra time. We think it would have appeared more satisfactory to exhibitors had the Committee, when the fourteen days had elapsed, sent round a little circular to exhibitors stating their difficulty.

In the last five months the value of eggs imported was £1,247,743; in 1875, £1,286,720.

### ROCHDALE SHOW OF POULTRY, &c.

THE annual meeting of this flourishing Society was held on the 23rd inst., in the grounds of Clement Boyd, Esq., J.P. The birds were placed in the open air with substantial wood pens fronted with wirework.

*Spanish* were first on the list, and these were of fair quality and moderately forward. *Cochons* were very good in both classes, *Buffs* winning except the first in cockerels. *Brahmas*, Dark cock first, a splendid bird, the remainder moderate. The pullets very well pencilled and sound in ground colour. Light were good, especially the pullets. In *Game* the Brown Reds were by far the best, the winners being well chosen. *Polish* were young, and were not of the highest merit. *Hamburgs* produced some capital chickens. Gold-spangled cockerels were very good so far as the winners were concerned, the second being highly promising. The first bird was about perfect, and was claimed, we were told, for £10 10s. In pullets were some almost equal to the hens in spangling. The Silver-spangled cockerels that won will be heard of again, both being of good quality; but the pullets were better than the Gold-pencilled cockerels. First a well-grown bird in good order; second quite young but a perfect bird. Pullets good and fine in pencilling, which worked well up the tail. The Silver-pencilled cockerels were not equal to the pullets, though the first was a very good one. Pullets very well grown and full of marking of the right stamp, but nothing was more perfect than the Blacks, for while three of the cockerels were near perfection, some of the pullets surpassed all the wish of breeders of but a few years ago, and it is quite certain that nothing has ever been seen equal to the first-prize bird. *Dorkings* were but moderate in quality; but the *Houdans* were much better in some points than we generally see them at this season, but bad in comb. *Malays* good and forward. To our surprise two Variety classes produced no entries. *Game Bantam* cockerels were only moderate except the winners, first being a Black Red, second a Pile, and third Brown Red. Pullets were better and showed to greater advantage than the cocks. The Variety class was made-up of Blacks and Sebrights, but the classes were not superior. *Ducks* and *Geese* were mostly of any age, as also the *Turkeys*, there being a capital show of these.

*Pigeons* were a grand display, the standard birds being much better than the other varieties, though, as a rule, most of the Pouters were very bad in feather, and the pens being somewhat small for them. In Carriers were some birds fit to make the eyes of an old fancier sparkle. Foremost among these being the Black cock shown by Mr. Fulton, and one placed second and shown by Mr. Hedley, the latter losing only in body, had an exquisite beak and eye wattle, the former being set on the right way. Several extra prizes were awarded. Among Tumblers were very good, an extra second being given. Mr. Baker's Kite was again to the front, with a good Red second, and Agate third. Balds and Beards producing better birds than we have seen of late. English Owls were divided into two classes, the Blues being best. Antwerps were a good entry, the awards being evidently made on no fixed standard, but as is often the case in accordance with the taste of the Judge. Fantails were very good. Dragons were large classes and mostly well placed. There were some very cheap birds in the Selling classes.

With a very good list and in the centre of the stronghold of the Rabbit club, we certainly expected to find more than ninety-two entries. Lop-eared Self-colour were rightly placed, but the broken colours were decidedly wrong. The first a Fawn-and-white, the second a Black-and-white, which we thought should have been first. Silver-Greys were not well placed, the best being left out altogether. As we have remarked before, condition seems to be no point with the Rabbit-club Judges. Angoras were a fair lot, and seemed to be properly placed, although

we had not the privilege of handling them. Himalayans were good and well placed as far as we could see. This remark applying also to the Dutch.

Eastwood. *Short-faced.* *Young.*—1, J. J. Bradley. 2, J. Wright. 3, C. Hopwood. *Chc.* J. Eckroyd. J. Wright (2). **FANTAILS.**—*White.*—1, Q. Blum. 2, J. Baker. 3, J. H. Smith. *Any other colour.*—1 and 2, J. Baker. 3, C. Blum. **DRACOONS.**—*Blue.*—1, W. Massey. 2, A. Bingham. 3, R. Woods. *Chc.* J. Eckroyd. W. Smith. *Young.*—1, R. Woods. 2, W. Smith. 3, W. J. W. Pass. *Chc.* R. Fulton. *Any other colour.*—2, W. Smith. 3, R. Woods. *Chc.* J. Baker. J. Eckroyd. *Young.*—1 and 2, W. Smith. 3, R. Woods. **MAGPIES.**—1 and 2, J. B. Bowden. 3, J. Baker.

**BIRDS FOR HOMING PURPOSES.**—1 and 2, W. Ellis. 3, T. H. Stretch. *Chc.* J. Lister. C. Thickett. *ANY OTHER VARIETY.*—1 and 2, R. Fulton. 3, A. Simpson. *Chc.* J. H. Smith. H. Yardley. **SELLING CLASS.**—*Single Bird.* either *Pouter* *Carriers.* *Tumblers.* *Foreign Owl.* or *Barb.*—1, J. Baker. 2, W. Markland. *Single Bird.* any variety not mentioned in the preceding class.—1, W. Markland. 2, T. H. Stretch. *Chc.* R. Fulton.

**RABBITS.**—**LOP-EARED.**—*Broken-coloured.*—1, Schofield & Barrett. 2, T. and E. J. Pell. *SILVER-GRAY.*—1 and 2, A. Hudson. 3, Schofield & Barrett. **ANGORA.**—1, J. Jones. 2, J. Jones. 3, R. Murgatroyd. *Chc.* J. Jewison. J. Jones. **HIMALAYAN.**—1, T. & H. Duck. 2, W. L. Burdett. *Chc.* P. O. Field. **DUTCH.**—1, Mrs. J. Foster. 2, J. R. Noble. Schofield & Barrett. *Chc.* E. Robinson. *ANY VARIETY.*—*Young.* bred by and the property of a Member of the Rochdale Fancy Rabbit Club.—1, C. G. Mason. 2, G. Brown. *ANY OTHER VARIETY.*—1, W. Lumb. 2, E. Robinson. *Extra 2.* H. E. Gilbert. 3, D. Oldfield. **SELLING CLASS.**—1, Schofield & Barrett. 2, D. Oldfield. 3, S. A. Clegg.

**JUDGES.**—*Poultry:* Mr. R. Teebay, Fulwood, Preston; Mr. E. Hutton, Pudsey, near Leeds. *Pigeons:* Mr. F. Esquilant, Brixton, London; Capt. R. Heaton, Worsley; Mr. H. Allsopp, Birmingham; and Mr. R. Brierley, Fishpool, Bury. *Rabbits:* Mr. W. Allison, Sheffield.

## HALIFAX SHOW OF POULTRY, &c.

THE thirty-eighth annual Show was held on the 26th inst., when the day was exceedingly fine and breezy and most enjoyable.

Game headed the list in poultry, and these were single birds. In Black Reds the cockerels were poor, but the pullets a better lot; but Brown Reds in both classes were superior to them, and in Duckwing pullets were some very good pens; but the highest quality was attained in the Pile cockerels in the Variety class, although these were not as well forward as some of the above. Next of great interest were the *Hamburghs*, which were a good lot; the Gold-spangles, winners at Rochdale, taking the cup for the best pen in the Show. *Bantams* were largest in number, and the pick of the season came to the front, the Black Reds being particularly good.

*Pigeons* were shown as often recommended by us—singly, and the entries were much greater than at previous shows, three of the London giants contending for the premiership; and excitement was worked-up to a very high pitch in Carriers especially,

where we saw more high-class birds in so small a group than at any previous Show. The first was a Black cock, shown at his best, and looking well in these pens, splendid in beak and eye wattle, and grand in neck and style, a point we contend for in Carriers. Dragoons were very good in both classes, as also the foreign Owls; and Jacobins and Fantails a smart lot.

**POULTRY.**—**GAME.**—*Black Red.*—*Cockerel.*—1, M. Jowett. 2, E. Winwood. *Pullet.*—1, J. Hird. 2, T. Dyson. *Brown Red.*—*Cockerel.*—1, T. Dyson. 2, J. Spencer. *Pullet.*—1, J. F. Walton. 2, T. Dyson. *Duckwing.*—*Cockerel.*—1, T. Dyson. 2, J. A. & H. H. Staveley. *Pullet.*—1, M. Jowett. 2, J. Tempest. *Any other variety.*—*Cockerel.*—1, E. C. & W. J. Mason. 2, G. Higgin. *Pullet.*—1, G. Higgin. 2, H. G. & W. J. Mason. **SPANISH.**—1, J. Roberts. 2, J. Newton. **DORKINGS.**—1, T. Brien. 2, J. Walker. **COCHINS.**—1 and 2, C. Sidgwick. **BRAHMAS.**—1, E. Pritchard. 2, W. Mitchell. **HAMBURGH.**—*Golden-spangled.*—1 and 2, G. & J. Duckworth. *Silver-spangled.*—1, H. Stanworth. 2, H. Pickles. *Golden-pencilled.*—1, G. & J. Duckworth. 2, H. Pickles. *Silver-pencilled.*—1, G. & J. Duckworth. 2, H. Smith. *Black.*—1, H. Pickles. 2, C. Sidgwick. **GAMB BANTAMS.**—*Red.*—1, A. S. Sugden. 2, E. Walton. *Any other colour.*—1, W. Shaw. 2, E. Walton. *Cockerel.*—1, W. F. Entwistle. 2, G. Walker. **BANTAMS.**—*Black or White.*—1 and 2, C. & J. Illingworth. *Any other variety.*—1, J. Walker. 2, E. Walton. *ANY OTHER VARIETY.*—1, H. Pickles. 2, F. Walton. **GESE.**—1, J. Walker. 3, F. E. Rawson. **DUCKS.**—*Rouen.*—1, J. Walker. 2, F. E. Rawson. *Aylesbury.*—1 and 2, J. Walker. *Any other variety.*—1, J. Walker. 2, H. B. Smith. **TURKEYS.—1, J. Walker. 2, F. E. Rawson. **SELLING CLASS.**—1, W. A. F. Fenwick. 2, C. Carr.**

Fulton. **SELLING CLASS.**—1, T. E. Hainsworth. 2, T. Foster.**

**JUDGES.**—*Poultry:* Mr. Teebay. *Pigeons:* Mr. Esquilant.

## WARMINSTER POULTRY SHOW.

THIS Exhibition was held on the 25th inst., and was an extremely satisfactory meeting. Mr. Hinton was indefatigable in his work, and the arrangements were admirable. If all poultry shows had such a Secretary there would very rarely be heard any complaints, for the feeding, penning, and dispatch to the station were all well done. The Judge was Mr. G. S. Sainsbury of Devizes, who has judged this Show since its commencement, and his awards were most carefully made and well received.

In the first class the *Houdan* hen of pen 4 (Sturt) was dead when she arrived. We viewed her body, and feel sure they must have had first prize, for the winning *Dorkings*, though large, were swollen in toes and out of feather. In the next class *White Cochins* were first; the hen large and white, but the cock a little out of feather. Capital adult *Light Brahmas* won second, and neat chickens of the same breed third. *Malays* were good, and were much superior to the *Game* in excellence. A large pair of birds won first; the hen was an adult, the other a very promising and large cockerel. Fair *Brown Reds* were second in this class, third going again to good *Malay* chickens. In *Bantams* *White-booted* won first, *Blacks* second, and *Black Red* Game third. In the *Variety* class a good pair of *Silky* chickens were first, adult *Silver Poles* second; the cock quite young, and promising to come out of his moult a fine bird; and very good *White-crested Blacks* third. The chicken class was splendid; it contained twenty-three pens of great excellence, and two firsts, two seconds, and two thirds were awarded. Very forward and large *White Cochins* won one first, and splendid *Malays* the other; good *Light Brahmas* and *Crèves* won the seconds, and *Brown Leghorns* and *Dorkings* the thirds. We noticed here a most promising pair of *White-crested Poland* chickens (Norwood); the cockerel is not quite ready yet, but of much promise.

*Pigeons* were very difficult to judge, for they were all classed together, and the quality was very fine. The first *Carriers* were very good in head properties and had smart carriage; second went to good *Black Barbs*, their beaks and eyes being very good; third to admirable true *Dragoons*, but they had begun to moult, and so their wing bars were not so prominent and perfect as they might have been; they were a very good pair, and deserved their place; highly commended (Randall) good *Burmese* and *Red Barbs* (Sugden). In *Toys* pretty *Turbis* (Red) were first, but their pen was so small they did not appear to advantage; second fairly cleanly-cut *Black Baldheads*; third very promising baby *Fantails*.

A fine pen of *Gold Pheasants* won first, and nicely marked *Guinea Fowls* third. In birds one of the most exquisite pairs of *Green Love Birds* we ever saw took first, an *Amazon Parrot* second, and a *Yellow-backed Whydah* in good feather third; highly commended (Miss J. Hinton) an *Amazon Parrot*, which talked splendidly, but was perhaps not quite in so full feather as the second-prize one. We furnish the awards below.

**POULTRY.**—**DORKINGS OR FRENCH.**—1, H. Astley. 2 and 3, J. Hall. **COCHINS OR BRAHMAS.**—1, Rev. R. S. S. Woodgate (White). 2, Mrs. Holmes (Light Brahmas). 3, H. E. Scammell. **SPANISH.**—1, ANDALUSIANS, MINORCAS, OR LEGHORNS.—1 and 2, H. Randall (Minorcas and Andalusians). 3, J. H. Bartrum (Spanish). **GAME OR MALAYS.**—1 and 3, J. Hinton (Malays). 2, J. Musprat (Game). **HAMBURGH.**—1, R. Strong. 2 and 3, not awarded. **BANTAMS.**—1, Rev. R. S. S. Woodgate (Booted). 2, J. H. Bartrum. 3, J. Lorraine. *ANY OTHER VARIETY.*—1, Rev. R. S. S. Woodgate. 2, J. Hinton. 3, T. Norwood. *ANY VARIETY.*—*Chickens.*—Equal 1, Rev. R. S. S. Woodgate, J. Hinton. Equal 2, H. E. Scammell, H. M. Sturt.

Equal 3, J. Hall, H. Randall. Ducks.—1, not awarded. 2, J. S. Maggs. 3, S. Eacott. PHEASANTS AND GUINEA FOWLS.—1 and 3, J. Lorraine. 2, E. F. Edwards.  
PIGEONS.—HIGH CLASS.—1, J. James. 2 and 3, Hon. W. Sugden. Toys.—1, J. S. Maggs. 2 and 3, E. Hinton.  
COTTAGERS' PRIZES.—1, H. Hills. 2, J. Gibbs. 3, W. Wells.  
CAGE BIRDS.—1 and 3, Mrs. Holmes. 2, Mrs. Wilcox.

### HETTON SHOW OF POULTRY, &c.

THE annual Show of this well-managed Society took place on the 23rd inst. in the splendid grounds of Hetton Hall, which are a treat to visit, let alone any other attraction. In previous years a tent was provided for the poultry, but this time they were tried in the open air, and fortunately the weather was favourable and all passed off well. Several other shows being on, some of the classes were small, but on the whole the quality of the winners was very good, and as a rule they were well placed.

Among the old birds the *Cochins* stood quite out in point of quality. The Gold-spangled *Hamburghs* being very good; Silver-spangled were placed as at Sunderland; Pencils were poor in feather and faded. *Game* good, Brown Reds winning. *Game Bantams* nothing extra, but in young birds they were very good; and *Hamburghs* as a whole only moderate in quality. In the Variety class of chickens Buff *Cochins* won both the prizes.

*Pigeons* were not numerous, but of fair quality. We were surprised that none of the Sunderland cracks were there.

#### OLD BIRDS.

POULTRY.—SPANISH.—Black.—1, R. Shield. DORINGS.—1, T. P. Carver. COCHINS.—1, 2, and 3, G. H. Proctor. BRAHMAS.—1, T. P. Carver. 2, R. Shield. HAMBURGH.—Golden-spangled.—1, R. Keenleyside. 2, T. P. Carver. 3, Holmes and Destner. Silver-spangled.—1, G. Alderson. 2, J. Hudson. 3, Holmes and Destner. Golden-pencilled.—1, T. P. Carver. 2, A. Stephenson. 3, J. Hudson. Silver-pencilled.—1, Holmes and Destner. 2, Davidson & Pattison. 3, D. Clow. POLANDS.—1, J. T. Prond. 2, T. P. Carver. GAME.—Red.—1, G. Carver. 2, Davidson & Pattison. 8, Holmes & Destner. Any other colour.—1, Holmes and Destner. 2, J. Dowell. GAME BANTAMS.—Red.—1 and 2, J. Robson. 3, T. Dowell. Any other colour.—1, J. Robson. 2, J. Mayo. 3, T. Dowell. BANTAMS.—Any variety.—1 and 2, Rev. H. A. Hawkins. 3, J. Mayo. DUCKS.—Rouen.—1, C. J. Young. 2, Rev. J. G. Milner. 3, W. Whitfield. Aylesbury.—1, F. E. Gibson. 2, and 3, M. Walker. #### CHICKENS.

POULTRY.—SPANISH.—Black.—1, Rev. H. A. Hawkins. 2, T. & R. Miller. DORINGS.—1, J. T. Prond. BRAHMAS.—1, R. Shield. 2, T. & R. Miller. HAMBURGH.—Golden-spangled.—1, J. Hudson. 2, W. Bearpark. Silver-spangled.—1 and 2, W. Bearpark. Golden-pencilled.—1, G. Davidson. 2, T. & R. Kidson. Silver-pencilled.—1, J. Hudson. GAME.—Red.—1, W. Bearpark. 2, T. & R. Miller. Extra, T. & G. Kidson. Any colour.—1, J. Robson. 2, G. Scarth. GAME BANTAMS.—Red.—1, D. Hunter. 2, G. Carter. Extra, J. Sanderson. Any colour.—1, J. Robson. 2, G. Scarth. BANTAMS.—Any variety.—1, T. P. Carver. 2, R. H. Ashton. POLANDS.—1, T. Bowes. ANY OTHER VARIETY.—1 and 2, G. H. Proctor.

PIGEONS.—CARRIERS.—1, P. Wilson. 2, G. Green. POUTERS.—1, P. Wilson. 2, P. D. Henderson. TUMBLERS.—1, J. G. P. Newby. 2, N. G. Willis. FANTAILS.—1, P. Wilson. 2, J. G. P. Newby. OWLS.—1, R. Hall. 2, J. Young. TRUMPETERS.—1, P. Wilson. 2, R. S. Magee. BARBS.—1, P. D. Henderson. 2, W. Chappelow. TURBITS.—1, T. P. Carver. 2, T. Bainbridge. JACOBIENS.—1, J. Young. 2, P. D. Henderson. DRAGONS.—1, W. C. Moody. 2, G. Barker. ANY OTHER VARIETY.—1, F. C. Fenwick. 2, R. S. Magee.

RABBITS.—LOP-EARED.—1, D. Hunter. 2, T. Johnson. ANY OTHER FANCY BREED.—1, M. Rowland. 2, J. Wakon. COMMON BREED.—1, J. Hudson. 2, J. Lawson.

JUDGE.—Mr. John Preston, Allerton, Bradford.

### BAWTRY SHOW OF POULTRY, &c.

THE second Show of poultry was held in Bawtry Park on the 22nd inst. The grounds are very excellent for the purpose, being in a central position, and are well adapted for a grand Show, but in this case the prizes were small and the classes few in number, but the entries were two hundred in all.

*Dorkings* headed the list; the first a very good pen. *Brahmas* a failure, if we except the first, a good pair of the Dark variety. *Cochins* a failure, but two pens of *Spanish* were very good, and the champion prize for the best pen in the Show was awarded to them. In *Game* we found some good specimens, particularly the first and extra Duckwing, a pen of old birds. In single birds a Pile was first and Black Red second, both very good. *Game Bantams* a fair class, all the prizes going to Piles, mostly chickens, and very promising. *Hamburghs* bad, except the first-prize Silver-pencils, which won the special. In the Variety class Gold *Polands* were first, and Silver *Sebrights* second. *Ducks* large and good; the first Rouens and second Aylesburys. The cup for the greatest number of points was won by Mr. Newbitt.

*Pigeons* were very good in some classes, while in others they were very bad, the Fantails being the worst. Carriers a moderate lot, while the Pouters were good; first a grand Blue cock, second a hen of that colour. In Barbs first was Dun and second Red, both cocks; and in Tumblers, first Almond and second Agate. In Dragons the first Blue was a good one all through, second a fair Red. Jacobins were the best class of Pigeons, and three prizes were awarded; first and third Reds, and second Black. Turbitts a nice lot; first a Silver hen, and second a Red of this year. Magpies very good, as also the Nuns; and in the Variety class first was a Trumpeter, and second a Fairy Swallow.

*Rabbits* had but two classes; the first prize was awarded to a

sober-looking little Black-and-white Dutch, which was nearly perfect; second to that being a Grey, a little more irregular in marking; and third to a Fawn. Lops were poor, except the first, which was a pretty fair Fawn-and-white doe. Point cup Miss Tofield.

POULTRY.—DORINGS.—1, W. Harvey. 2 and 3, W. G. Lysley. BRAHMAS.—1, J. Wells. 2, H. Digby. COCHINS.—2, W. Gibbs. 3, C. A. Swindin. SPANISH.—Extra 1 and Champion Prize, J. Powell. 2, E. Marriison. GAME.—Extra 1, H. C. Mason. 2, W. Wilcock. 3, J. N. Jackson. COCK.—1, H. C. Mason. 2, J. Woods. 3, J. N. Jackson. GAME BANTAMS.—1 and 2, E. Newbitt. 3 and 4, H. Elwis. HAMBURGH.—Gold or Silver-spangled.—Extra 1, J. Ward. Gold or Silver-pencilled.—1, Extra, and 2, H. Digby. ANY OTHER VARIETY.—1, W. Harvey. 2, W. Bygott. 3, Mrs. Mellish. DUCKS.—1, Miss E. Tofield. 2, Dr. E. Snell. 3, W. Bygott. GEES.—1, T. Stephenson. SELLING CLASS.—1, Miss E. Powell. 2, Miss E. Tofield. 3, J. N. Jackson. LOCAL CLASS.—1, Miss E. Tofield. 2, R. Hoyle. 3, H. Wilson.

PIGEONS.—CARRIERS.—Cock or Hen.—1 and 2, Miss E. Tofield. 3, J. Kendall. POUTERS.—1, 2, and 3, Miss E. Tofield. BARBS.—1 and 2, Miss E. Tofield. TUMBLERS.—1 and 3, J. Kendall. 2, Miss E. Tofield. FANTAILS.—1, J. F. Loveridge. 2, Vaughan & Heath. DRAGONS.—1 and 2, J. Kendall. JACOBIENS.—1, J. Kendall. 2 and 3, J. Powell. 4 and 5, Miss E. Tofield. TURBITS.—1, J. Kendall. 2, F. Down. 3, J. Carrill. MAGPIES.—1 and 2, Miss E. Tofield. 3, J. Carrill. NUNS.—1 and 2, Miss E. Tofield. 3, J. Carrill. ANY OTHER VARIETY.—1 and 2, Miss E. Tofield. 3, J. Kendall. SELLING CLASS.—1, 2, and 3, Miss E. Tofield.

RABBITS.—LOP-EARED.—Buck or Doe.—1, J. M. Mander. 2, J. Taylor. ANY OTHER VARIETY.—Buck or Doe.—1, J. G. Abland. 2, J. M. Mander. 3, R. Newbitt.

JUDGE.—Mr. E. Hutton, Pudsey.

### NEWBURY POULTRY SHOW.

GOOD summer shows in the south of England are few, and a well-managed one at a time when chickens begin to make their appearance in the exhibition tent is sure to be a success, especially if it lasts but one day, for this arrangement (we can personally vouch for it) attracts many exhibitors of young stock who would not submit their birds to two or three days' confinement. Under such conditions was the Newbury Show held on the 22nd inst. It is but the second meeting of the Society, and as there were over five hundred entries it bids fair to become a leading show. The grounds at Speen in which it took place are exceedingly attractive. From a neat old-fashioned garden a park descends rapidly, with abundance of magnificent elms for shade. After a threatening morning the day came out hot and lovely, and crowds of people seemed to enjoy the fête. There were three splendid marquees—two filled with singularly good flowers and exotics, the third devoted to the poultry. The Show was particularly interesting from the first appearance of many remarkable chickens, some of them prodigies of size for their age, destined, probably, to be among the most renowned winners of the year.

Eighteen classes (for the most part for single birds), and all for birds of any age, came first, with a champion cup for the best pen in the section. This was awarded to a very pretty Light *Brahma* pullet. Dark *Brahmas* headed the list. The winning cocks all good; the first in by far the best feather. Of the three prize hens the two first were wonderfully marked; the third, too, a good Dark bird. The Light *Brahma* cocks were fair; the hens, or rather pullets (for all three winners were apparently pullets, though one was stated to be five years and a half old), excellent. Mrs. Acton Tindal's famous old winner was obliged to be content with a highly commended. *Cochins* were, generally speaking, out of condition, as they always are in August. The first-prize birds, both cock and hen, in the Buff classes were well placed, and singularly characteristic specimens of the true *Cochin* form. In the Variety *Cochin* classes Mrs. Acton Tindal took both firsts with Whites, remarkable rather for shape than great size. Partridge were in each class second, the cock a splendid bird. *Dorking* hens were better than the cocks, save the first-prize cock, a fine Silver-Grey. The first hen was an excellent Dark bird, the second a large White well shown. *Game* were, save the first cock and two prize hens (Brown Reds), in wretched condition. The third prizes were properly withheld. Two pairs did duty for *Spanish*. The least bad of them was fortunate enough to get a third prize (no third was offered in the schedule!). The other pair were really remarkable creatures—red-faced, and the cock had the most singular comb we ever saw, about 4 inches high and 1½ inch broad, in shape a parallelogram, and somewhat resembling the Shah's head-decoration. *Polish* were a good class. We were glad to see a capital pen of White-crested Blacks first, beating good Golden and Silver. We often think this handsome and useful breed is unfairly put behind the other varieties. *Hamburghs* do not deserve mention. Black *Hamburghs*, Crêves, and Malays won in a tolerable Variety class; and in *Bantams* Black Rose-combed birds were an easy first.

The chicken classes were far better than the latter of the general classes. A cup was offered and awarded to the first *Brahmas*, a very forward Dark pair, shown by Mr. Pritchard; the pullet was of that very dark type which we much admire, with really black markings on a white ground. Second were Lights, and third Darks. The cockerel in the latter pen, if we mistake not, will develop into a very fine and remarkable bird. The first prize for *Cochin* chickens went to a marvellous pair of Partridge shown by Mrs. Acton Tindal. The cockerel, though still not spurred, is a perfect giant; the pullet exquisitely

marked, though we must say we did not like her very thick feathering on the inside of the legs; she was apparently moulting, and the multitude of short quills to our idea somewhat marred her beauty. The same exhibitor took second with a capital pair of Whites; the pullet a great beauty. In Dorking chickens all varieties save White appeared. First were an excellent Dark pair, second Silver-Grays pressing them closely. The latter variety seems decidedly advancing upon the Dark one. The class for chickens Any other variety was well filled. Malays, White-crested Polish, and Silver-pencilled Hamburgs won. In the two latter pens we preferred the pullets to the cockerels. A very highly commended was deservedly bestowed on some Silver-spangled Hamburgs; indeed, all the highly commended pens were good.

Ducks were not remarkable. In the class for Aylesbury or Rouen fine Aylesburies were first and second, Rouens third. Mr. Sainsbury's Black East Indians did not at all look themselves at this season.

In Pigeons two classes were given to Pouters, the same number to Carriers. The cup for the best pen of Pigeons went to Mr. Warren's Blue Pouter cock, a very grand bird. Dragons and Antwerps were very numerous. In Dragon cocks two Blues were first and second, a Yellow third; in hens a Yellow, Silver, and Red won. Most of the winning Antwerps were Red Chequers. Mr. E. Kendrick's cup cock is a perfect bird, very short in face. The first-prize Fantails and Tumblers were well ahead, as also Mr. Allen's White Owls first in the Variety class. Foreign and British birds each had a class. In the former a pair of Golden Pheasants were marked first, though in the schedule the class is for "the best bird;" a Lory took second, and a Green Parakeet third. A very tame and lovely Nightingale richly deserved its first card in the British class.

The Local classes were not, as a whole, so well filled as could be wished. The cup and several firsts were carried off by Mr. Ridley. We doubt if the proximity of so great an exhibitor promotes local entries. The cup Light Brahma cock, two Dark Brahma pullets, and a Coloured Dorking cockerel (barring his white earlobes), all good, the first-prize La Flèche cock and hen in the two Variety classes super-excellent. The Committee seemed very attentive and courteous.

Mr. W. J. Nichols judged both poultry and Pigeons.

The prize list did not reach us in time for publication this week.

### DISEASES OF PIGEONS.

THE best thanks of the fancy are due to Mr. J. H. Hutchinson for his article on this subject in page 177. I have cured wing disease by simply plucking the flight feathers of the wing affected, but have never been successful with any internal complaint, at least so far as I can recollect. What does Mr. Hutchinson say to the following case? I have a good warm loft, I live in the country, I keep but few birds (Jacobins), they have their liberty, they are kept very clean, and have the best of food and purest water. As a rule they are very healthy, but this year one pair has bred young birds cankered in the mouth—sometimes one, and at other times two of the young birds being so diseased. Last week two, hatched fine birds, died at about a fortnight old; their mouths were full of a white core, and upon that being removed (and it easily came off) there was a black and bloody sore like a grape in each throat. All the food given by the parents—sound peas, rolled into the nest, water only passing into the crops. The birds died of starvation, as there was no room to swallow. What would Mr. Hutchinson do in such a case? Is there a cure for birds so young?

Then, close to the pair breeding these diseased young all the season were other pairs, but not of the same strain—eating, drinking, and at liberty just the same—which have not had one single cankered young one. Does not this look like a case of hereditary disease? or why, if not, were not the young of other birds similarly affected? No doubt there is much in persevering with remedies, and some fanciers, like some people, have a natural turn for doctoring. Waiting Mr. Hutchinson's kind reply and advice, I remain as yet—A PUZZLED FANCIER.

### THE TORMENTORS OF OUR CAGE BIRDS.

OWING to the very warm summer we have had the multiplication of acari has been greatly favoured, and it may be advisable to remind bird fanciers that, in the case of the Finches especially, the birds suffer much discomfort, and may even have their lives shortened through the acari that are frequently introduced with the seeds. It is in vain to wash our birds or dust them over with insect-killers if we are perpetually bringing in unawares fresh pests. These acari, though like the hateful *Cimex lectularius* they can subsist on vegetable substances, much prefer blood when they can get it, and from the seed-bottle or drawer they easily transfer themselves to the plumage of birds or crawl out on the perches. It does not appear to be always possible to keep seeds free from these, but their increase

is hastened by the careless way in which seeds are stored by both wholesale and retail vendors, and there is a neglect of the process of sifting. All parcels of seeds should be looked over when purchased, and the dust examined more particularly. Rape and hemp seem chiefly to be resorted to by acari, canary and millet seeds less frequently.—J. R. S. C.

### REARING STOCKS AND FILLING SUPERS ARTIFICIALLY.

FAVOURABLE accounts with many questions come from many parts of the country. "My bees have done well this season. I have a great deal of run honey and some fine supers of comb. Will you kindly give me the name of a buyer of honey, or sell mine for me?" "Most of my hives are well filled and heavy; I don't know which to keep and which to put down. Can I cut some of the honey from them and keep all for stock? Some of the supers are not full, and the bees have not stored-up honey for some days though the weather is fine. How shall I succeed in getting the supers filled?" This is the sum and substance of many letters. One working man in Nottinghamshire wants to come over to see bees driven, as he knows of no way but the brimstone pit of taking the honey from his hives; he has twenty-two hives. Three working men in the north of Lancashire having read a well-known book on bees have entered into partnership, have increased their stock to nineteen hives this season, and are now seeking hives into which they will drive the bees from their honey hives on their return from the moors.

In answer we have to say, first, that we do not give the names of buyers of honey. Almost all who keep bees find in time a market for their honey.

Hives that weigh 60 lbs. contain about or above 30 lbs. of honey. We take, and advise others to take, the honey from such hives. The honey is worth 30s. or 35s. If the bees were driven into an empty hive and fed with sugar syrup the gain in cash would be more than 20s. Hives of 70, 80, and 100 lbs. weight should not be kept for stocks, as the great stores of honey in them would hinder healthy progress. "But the quantity of honey can be greatly reduced and still leave enough for the bees?" Yes, this may be done, but in our opinion it is better to drive the bees out and take all the honey, then feed them into stocks.

In giving syrup to swarms put into empty hives it may be given either too fast or too slow. If given too fast at first the bees are apt to build their combs rather thick and dumpy by elongating the cells. In times of rapid honey-gathering they do the same—build either dumpy or drone combs. If given too slow the bees live on it to a great extent, and do not build combs or store-up honey enough. We think it best to give the syrup in small doses for two or three days. After the foundations of five or six combs have been laid in a hive the bees may be fed more rapidly and kept at comb-building for a fortnight. If 20 lbs. of sugar (about 40 lbs. of syrup) be administered to a swarm of 5 lbs. in a 16-inch hive, in fifteen days the hive will be nearly filled with combs and their centre parts well filled with brood. To promote comb-building and breeding the hive should be kept warm by contracting the door and being well covered. There should be no cessation of feeding till all the syrup be given.

In filling supers artificially with combs and then giving the bees honey to store-up in them, it should be given to them as fast as they carry it up, for if bees are long in filling supers there is danger that breeding may be resorted to in them. If breeding begin in supers it is rather a difficult matter to get them well finished; but if brood be seen in them it should be cut out clean, and honeycombs from other hives placed in vacant places.

In feeding swarms into stocks it is of little importance whether they be fed from the top or bottom of the hives, but in filling supers the bees should be fed from below, for the less traffic and work done over sealed combs the better they look. The bloom can be taken off honeycombs as well as off grapes. If honey be built and finished downwards the honey should be carried upwards. Bees naturally do not sit on or travel over finished honeycomb, and in all artificial schemes the more closely nature is followed the more likely are we to succeed.

In filling supers on empty hives by feeding, the bees are apt to bring the combs down through the crown holes of the hives before the supers are finished. To prevent this the bee-keeper's ingenuity is called into play. It may be done sometimes by two supers, one above the other. While the top one is being finished the bottom one is being filled; thus all the honey given goes for super work and storing. In this artificial work we use only the purest virgin comb and the best of honey.

It is worth while to remember that all honey gathered from field flowers is first deposited in the brood and pollen combs; afterwards the indoor workers remove it to and store it in the virgin combs outside the brood combs and in supers. It is fortunate for the bee-master that his servants do not go from the fields with soiled feet and baskets of pollen on their legs to the

virgin combs of his hives. No field labourer is permitted to enter the best rooms of the house; the housemaids only carry the honey aloft.—A. PETTIGREW.

### HONEY EXHIBITION.

I SEE advertised an exhibition and sale of honey at the Alexandra Palace similar to that of last year at the Crystal Palace. Last year I sent up for exhibition and sale more than ten stones of honey. Though carefully packed by experienced bee-keepers here, I received from the Secretary a notice that it was all "smashed to pulp and utterly unsaleable," except as run honey at 10d. per lb. Finding, however, by the papers that I had won several prizes I wrote to make further inquiries; the reply was still the same. I have good reason to believe that my honey was afterwards sold in very fair condition indeed and in the comb. Through what I consider as mismanagement my poor cottagers, to whom, as was stated at the time, most of my honey belonged, have sustained serious losses. What guarantee do the Association give that such a similar fate will not this year overtake honey belonging to country exhibitors who cannot themselves attend the Show to look after it?—C. N. GRAY, Vicar of Helmsley, York.

### "THE MASSACRE OF THE INNOCENTS."

THE honey harvest now commencing is, I think, the time to enter a protest against the wholesale consignment of bees to the sulphur pit in order to take the honey. If the best market for honey could be pointed out, much, I think, might be done towards stopping the massacre of the innocents and converting their golden stores to hard cash. Many cottagers do not cultivate bees because they do not know how to dispose of the produce.

I went to a cottager's garden recently and saw a lot of hives in rows. The owner hesitated about taking the honey; he did not know how to take it otherwise than by stifling the bees, and when he had secured the honey he did not know how to dispose of it. "The missus didn't care about it, and didn't like the nasty stinging brutes." He thought he had nearly sold one hive.

I offered to drive his bees, give him the hive and honeycomb for the bees, which so shook his old superstitious notions that his hands fell down by his sides, and he expressed the utmost astonishment, remarking, "You must be daft [the polite term] to think of taking bees in broad daylight."

The above is only one instance, and I could give many more. Here is a man who will rise at 3 A.M. and work till 9 or 10, harvesting for a few shillings, and yet cannot turn to account the rich stores the "busy bee" has been gathering for him all the summer, from ignorance of ways and means of selling the honey and saving the bees.

I am informed this morning that the practice of killing the bees is general. I do what I can to stop the slaughter in this neighbourhood, and am anxious to assist in stopping it throughout the country.—GEO. W. JESSOP, Chertsey, Surrey.

### HONEY RECIPES.—No. 3.

THE prize dish of honey pastry at the Crystal Palace comprised several varieties of puffs and tarts where honey took the place of jam, and among them were the following.

**HONEY CAKES.**—1 lb. of butter,  $\frac{3}{4}$  lb. of honey,  $1\frac{1}{2}$  of flour, eight eggs. Butter and honey to be well mixed, and then the eggs added and well beaten together, and lastly add flour. Bake to a nice light brown colour.

**HONEY SHORTBREADS.**—Half a pound of honey, half a wineglass of cold water, two eggs, half a pound of butter,  $1\frac{1}{2}$  of flour. Mix the honey, water, and eggs together, then rub the butter into the flour, then mix the whole together very lightly and bake in a moderate oven. This quantity is sufficient for about twenty-five cakes.—JOHN HUNTER, Eaton Rise, Ealing.

### OUR LETTER BOX.

ADDRESS (Jane).—O. E. Cresswell, Esq., Early Wood, Bagehot.

COCK'S SPUR ABSENT (Amateur).—The loss will not disqualify him for exhibition, but a bird equal to him in other points and not deficient of a spur would be preferred by the judges.

PERCHES FOR COCHINS (C.).—We do not find them prefer the nests to the perches, but we did so till we altered our arrangements, and we now find them answer perfectly. Our house is a large one, and we keep from eighty to ninety fowls in it. Our perches stand on tressles at one end, and a ledge fastened to the wall at the other. When it is time they should go out the perches are piled in a corner, and the tressles removed. They are not put up again till it is near roosting time, when the fowls occupy them directly. Broody hens often squat in the nests, but we drive them out. If all other means failed we would remove the laying boxes for a time.

WASHING POULTRY (R. W., Hants).—Take some soap and water, and with a piece of flannel or sponge wash the plumage by wiping it the right way of the feathers. It is only the outside of the plumage that is dirty. If you see a white-feathered bird that is very dirty to look at, and you raise the

feathers, you will find they are perfectly clean underneath. You must then continue to wash by wiping gently, and above all, the right way of the feathers, changing the water frequently. When it is clean then put the bird in a basket with plenty of soft straw, and stand it in the sun till it is dry. In the winter when there is no sun the bird must be put before a fire till dry.

**TURKEYS' HEADS SWOLLEN (C. M.).**—Your young Turkeys have the roup. They are subject to it. It is gained either by roosting in a house with wood, stone, or brick floor; roosting where there are great draughts; or by being allowed their liberty with the hen in wet weather, or very early in the morning. Wash their faces with cold water and vinegar, feed them well on bread and ale, and give them pea and bean meal mixed with milk, with onion and nettle tops chopped fine and mixed with it. Above all, do not let them out in the morning (especially now we may expect frosts) till the sun is up and the grass dry, and let them be fed before they start. Do not give any rice. Ground oats slaked with milk, and bread and milk, are both good for feeding.

**FANCY RABBITS (G. F.).**—Write to Mr. Bailey, 113, Mount Street, Grosvenor Square.

**RABBITS (T. S. R.).**—Himalayan Rabbits have not long hair, and one having the head of a Himalayan and the skin of an Angora ought certainly to be disqualified if exhibited in the Himalayan class.

### REMARKS.

23rd.—A very fine day, but comparatively cool.

24th.—Another fine pleasant day, bright but cool; a slight shower.

25th.—Bright and fine, but from the wind being northerly it was rather cold.

26th.—Rather dull and very cool, looking likely for rain during the day, but it did not really rain till after 7 P.M., not heavy but rather windy.

27th.—A very pleasant day, at times very bright, and at other times cloudy; a very slight shower at 1.30 P.M., and again at 4.50 P.M.; fine after.

28th.—Cloudy morning; dull day; rain commenced at 5.30 P.M., and the evening was wet.

29th.—Windy morning and forenoon; bright, pleasant, but rather cool day. Temperature generally nearly 10° lower than in the previous week. This marked fall has also been noticeable in the temperature of the soil, which has fallen from 70.8° on the 18th to 60.5° on the 29th.—G. J. SIMONS.

### COVENT GARDEN MARKET.—AUGUST 30.

THE market is now very thinly supplied with nearly all classes of goods with the exception of Apples, there being a larger quantity arriving than was anticipated, but prices remain much the same, business being generally very quiet. We are now receiving the usual large consignments of Grapes from the Channel Islands, causing a great fall among ordinary samples of home growth.

From observations taken near London during forty-three years, the average day temperature of the week is 69.8°; and its night temperature 46.6°.

## LILIUM AURATUM.

HE continued importation of this bulb is surprising. The sale of several thousands in one day by Mr. Stevens has for many years past been an ordinary occurrence. By this time no moderate-sized garden ought to lack them. But what is the fact? They are still unknown, except in the gardens of the few. Where, then, are the bulbs? Why, dead.

I have been induced to write a few lines on the subject from reading in a contemporary that at Cheshunt, where this Lily is cultivated largely, the bulbs are taken up every autumn to save them from the winter rains, which rot them. If this be the secret of success it is easily obtained; but most cultivators think that all Lilies are impatient of any disturbance at their roots.

When *L. auratum* was first imported the price was so high that no one dared venture the bulbs in the open ground. But they did not thrive in pots, and it is now held that potting is a mistake. I did once see a magnificent potted plant. It had been repotted year by year into larger sizes without the slightest disturbance of the ball, and was growing in a very large pot in a greenhouse with a north aspect, and threw up nearly sixty stems.

The recommendation now given is to plant in a peat bed among *Rhododendrons*, and leave the bulbs alone. But everybody does not live at Bagshot, and peat is to most a costly article.

The question then, which I propose rather than answer, is, What are gardeners to do whose stock of peat is limited? and we shall better approach the subject if we can discover what are the causes of the bulb dying-off when away from the *Rhododendrons*. I assume that it is carefully planted—that is, that a hole has been dug out filled with a mixture of peat, loam, sand, and stones (or broken bricks), and the bulb so placed as to have its top 6 inches below the surface. I like a little pure sand just round and below the bulb.

In the autumn of 1874 I bought a dozen of the finest imported bulbs, and dividing them into three parcels planted them out, after having cut away every speck of decay. The garden lies high and dry on gravel. All the bulbs came up well in the spring. Their final fate was as follows. No. 1, planted on an open sunny border, turned purple just before flowering, and every bulb was found rotten. No. 2 was in front of a south-east wall, but partially shaded by a row of espaliers before it. The spot was selected because *Lilium bulbiferum* thrives there remarkably well. Here *L. auratum* grew well, one bulb only perishing. This year the remainder grew strongly, but after showing flower all have died but one. No. 3 was in a Rose bed, the soil of which was made in great part of loam. The situation is exposed. There is shade from the Roses, but no great amount. Here in 1875 were capital flowers, and no loss. In 1876 still free growth, still larger flowers, but one plant full of flower buds turned purple, and is gone. All three clumps have had artificial

watering just the same as other plants which were near them. No. 3 had the advantage of the more copious supplies given to the Roses, with liquid manure besides.

It would seem from the above that, on dry soils at least, winter damp and cold do no injury, nor do spring frosts, for this spring was a trying one. If so, we are led to look to the sun and drought as the sources of our ill success. But it is difficult to imagine that the direct rays of the sun can penetrate 6 inches into the soil and there do harm, or is it the effect of the sun upon the foliage? If the sun be in any way the destroyer, the cure is easy enough—plant in the shade. But then comes the question whether in damp gardens the bulbs will stand the winter there. If the rays of the sun do no harm, and it is only a question of summer drought, then careful watering is the cure.

I hope this letter may induce others to give their experience, and perhaps it may meet the eye of some one who has seen this Lily in its native land, and can tell us what are its conditions in a wild state. It is a gorgeous plant, well worth some trouble; but to my taste *L. longiflorum*, *L. eximium*, and *L. speciosum rubrum* are more elegant and more delicately perfumed.—G. S.

[Our correspondent alludes to a matter of considerable importance, for *L. auratum* cannot be seen in all its beauty except when growing in the open ground. In the garden of Mr. McIntosh at Duneevan it grows in wild luxuriance, and the bulbs are not removed from the ground in winter. Last year a plant in that garden attained a height of 11 feet; and this year, although the summer has been so dry, the same bulb has thrown up a spike 10 feet 6 inches in height. In the same garden this year one clump, the offspring of three bulbs, has produced 170 flowers. The soil in which these *Liliums* thrive in such a remarkable manner is sandy loam having an admixture of peat, the subsoil being sand. They are growing among *Rhododendrons*, and are watered copiously. Scarcely any bulbs perish during the winter, and the plants are seldom injured by spring frosts. Partial shade and liberal supplies of water are regarded as the main elements of success in the case of these remarkable *Liliums*, and the experience of "G. S." confirms the importance of these requisites. We shall be glad to hear of the successes or failures of others in their attempts to establish *Lilium auratum* as a garden flower.—EDS.]

## GRAFTING VINES—PUTTING ON GRAPES.

HAVING had considerable difficulty in obtaining fruit from a large and luxuriant Black Hamburg Vine I carried out a suggestion which was some time ago made in your pages, and I have succeeded in placing on the hitherto fruitless Vine some satisfactory bunches of Grapes. "Placing on" the bunches is a somewhat unusual term to use in reference to Vine culture, but it is literally true; for the Vine of itself showed no bunches for fruit, yet by artificial aid became the foster parent of an excellent crop, which was (in embryo) placed on at during the spring of the same year. The Vine was an

old one, but apparently in robust health, for it grew vigorously, producing long-jointed wood, large leaves, long tendrils, but no fruit. It was pruned on the short-spur system, and everything that was possible was done to ripen the wood, but no fruit followed. The long-spur or extension system was then tried, and a few bunches were obtained from the young canes, but by no means a good crop. I then had recourse to the plan of "putting on" the bunches.

Short-jointed and well-matured wood from fruitful Vines was preserved by burying it an inch deep in the open garden. In the spring when the barren Vine commenced putting forth leaves the dormant yet fresh pieces were dug up and grafted on the old and then freely-growing stock. The grafts were for a time supported with "the bottle"—that is, until their union was complete and they received support from the stock. The grafts were 18 inches long, and from the centre of each a deep slice was cut 6 inches in length, starting at two eyes from the top. Corresponding slices were cut from the parent, some on the old rod and others on the laterals, which had been purposely left unpruned, and the cut parts were neatly placed together, and were secured by matting and protected with moss. The lower end of the grafts, which were about 8 inches in length, were inserted in bottles of water—common wine bottles—which were suspended from the roof. These bottles were kept filled with water for a considerable time. In due time the buds swelled and the young growth grew just as freely as if it had been a part of the Vine. Bunches were seen, and each shoot from the graft was stopped a leaf or two beyond the bunch. The growth of the "stock" Vine was also restricted, and during the same season good bunches of really fine Grapes were ripened on the Vine that had previously been barren for years.

Another noteworthy fact remains to be told. The short-jointed fruitful wood that was "put on" the Vine producing long-jointed unfruitful canes has in a measure retained its short-jointed and fruitful character, and for three years has produced satisfactory crops of Grapes, yet not quite equal to the crop which was produced during the season of grafting.

Perhaps the success attending this experiment may be worth recording. The operation is so easy of being performed that no one need hesitate to try it. A sharp knife, a steady hand, and a quick eye being the principal requisites in "effecting a junction," and subsequent attention to stopping the growths—on stock and graft—"keeping the bottles filled," and thinning the fruit will result in Grapes which have been "put on" the same season. Possibly others may have adopted the same plan; if so, I should be glad to hear if they have been equally successful.

I only regret that I did not try several varieties on the same Vine, for apart from the interest attached to their so growing, it would have been instructive to have noted what effects, if any, the stock had over the grafts. A vigorous parent is no doubt necessary to insure success.—A DOCTOR'S GARDENER.

### IXIAS: A PLEA FOR THEIR CULTURE.

It has often surprised me that so few people apparently seem to cultivate this very beautiful tribe of bulbs, and it is probably from the notion that there is some great difficulty in the way. This has perhaps been increased by the fact that when persons have been struck with astonishment at the beautiful groups of them exhibited by the Messrs. Hooper of Covent Garden, and have asked about them, they have been informed that they were grown in the Channel Islands, and have hence concluded that it is only in such favoured localities that their cultivation can be attempted. This is a mistake, at least as far as frame and pot culture are concerned; and it is in order to do away with this feeling and to encourage others that I venture to write a few words in favour of Ixias.

In my own little way I have hitherto attempted their culture only in pots; but knowing that Mr. Samuel Barlow of Slakehill House, Chedderton, near Manchester, was a most successful grower of them, I asked him for some information concerning them; and as his method differs but little from my own, except in the larger quantities in which he grows them, I give the notes with which he was kind enough to furnish me. "I grow my Ixias in a mixture of good turfy soils and one-fourth well-decayed cow dung. I also add a little rough sand and a sprinkling of finely powdered clay and marl containing plenty of lime, about one-tenth of each of these two, and all well mixed together. I grow them in large 15-inch pans 9 inches deep, and about eighty bulbs in each, and keep them

in a cool house or frame. The soil must be rich and fibrous, not too light. When the spikes begin to show for bloom I give weak liquid manure about every third or fourth day. I may say that if protected from frost they will bloom well out of doors."

I have not been able as yet to grow them in such quantities, but find that about half a dozen bulbs in a large 48-pot answer very well, and their elegant and graceful habit, together with their brilliancy and quaintness of bloom, makes them very effective objects; while all who are desirous of having pretty flowers for cut blooms cannot very well dispense with them. For light vases or the top of a March dinner-table stand they are most valuable.

With regard to sorts, I do not think there are many more than two dozen varieties. One never sees much more than that number in a catalogue; and although there are different names in the various lists, yet I am inclined to think this rather arises from the growers in Holland who supply the English dealers having them under different names. I add those which I have found effective and useful:—*Viridiflora*, a most quaint light-green-coloured flower with dark centre; long spike. *Aspasia*, white, purplish stripes; maroon centre. *Craterioides*, bright scarlet. *Golden Drop*, yellow; dark eye. *Pallas*, cream; back of petals striped lilac. *Grand Duke*, straw colour. *Hector*, large purple. *Virgilius*, bright lemon; large, dark centre.

I have also grown in the same method the kindred bulbs of *Sparaxis* and *Babianas*, but I very much prefer the *Ixias* to them as being more light and graceful.—D., *Deal*.

### TREE PLANTING.

"Jock, when ye hae naething else to do, ye may be aye sticking in a tree; it will be growing, Jock, when ye're sleeping." When Sir Walter Scott put these words into the mouth of Dumbiedikes he made the old laird give advice of the utmost value to thousands as well as to "Jock." I am only afraid that in following it but too many have shown by their practice a too literal application of the "sticking-in" part. By all means plant, but let it be well done or not at all. "Well done" in the sense in which the words are now used is a most comprehensive term. It means putting the right tree in the right place; right for the future as well as the present; right as to soil and climate and as to the influence which it will exercise upon surrounding objects, be they other trees in the depth of a forest or the features of an open landscape; and, above all, right as to the preparation of the soil and the manner in which the roots are placed in it—all matters of the utmost moment, and to which due weight must be given in order to obtain successful results.

Take the Larch as an example of this. No doubt, as "A FORESTER" says, in his very sensible and practical remarks on this subject in page 160, "the liberal planting of Larches is profitable," but then it must be well done in every sense or a most pitiful failure will ensue. I have frequently seen Larch planted among underwood of one year's growth from the fall or time when the whole wood was cut, planted and left to take its chance till the next fall, a period of eight or ten years, when the underwood is cut clean away, leaving the Larch with their thin, bare, weakly stems exposed to the risk of being blown over by the next storm, which very often happens if the Larch clump be not a large one. It is clear, therefore, that if Larch is planted for timber among underwood it must have a certain space kept clear around it to admit of a stout robust growth; it will then soon beat the underwood, and by the time of the next fall be so sturdy as to withstand the roughest storms.

My object, however, is not so much to call attention to the management of the Larch as a timber tree, valuable though it undoubtedly is in that form, but rather to show how profitable it is, and how superior to many other trees upon a poor soil. The soil here is poor, thin, and light, and about a hundred acres of it is covered by a wood consisting principally of Oak and Beech irregularly dispersed a long distance apart, with an undergrowth of Oak, Beech, Hazel, Ash, and Chestnut, subjected to a periodical cutting for hop-poles, faggots, &c., every eight or ten years. Some of the strongest poles will in that time reach a height of 18 to 20 feet, but the majority will be not much more than half that height. Now, having heard from a reliable source that plantations of Larch had proved four or five times more profitable than the kinds of trees growing here, and that too in a similar soil, I was glad to find an opportunity of testing the matter, and the conclusion

I have arrived at is that my information was rather under than overstated.

In January, 1873, I planted a quantity of Larch—sturdy plants 3 to 4 feet high, and costing 40s. a thousand—upon an open piece of meadow land which was trenched, or rather half trenched, for it was not stirred deeper than 14 inches. The trees were planted 4 feet apart with a *Pinus austriaca* at intervals of about 30 feet, the intention being to have the Larch as nurseries for the Pinuses for a time, but to cut them gradually away as they became large enough to make that a profitable process. The growth of the Larch has quite exceeded my expectations, the shortest plants being now upwards of 9 feet high, while the majority of them are considerably taller; two of the finest which I have measured to-day (August 25th) are both nearly 13 feet high, one of them having actually made a growth of 3 feet 10 inches last year and the other 3 feet 5 inches. They are now growing freely, but I do not think they will make an advance of 3 feet this year, the brown and yellow foliage affording clear evidence of suffering from drought. A very slight calculation will show that at this rate of progress a crop of Larch must prove very profitable, whatever might be the purpose for which it is eventually intended; if for poles the entire wood could be cleared at one time, or if for fencing and timber a gradual clearance of the weaker trees would give space to those intended for timber, and at the same time afford a handsome profit upon the work.

Whatever be the nature of the soil in which we desire to plant Larch, I would always advocate trenching, even deeper by several inches than I have gone, for it undoubtedly induces not only a rapid growth upwards but a proportionate stoutness of stem, both eminently desirable properties, whether the object in view is simply a free handsome growth or a profitable return for money invested in the work.—E. LUCKHURST.

### VIOLAS.—No. 2.

THE ennobling of Violas into Pansies is inevitable; the varieties of Viola raised hitherto only mark the stages through which a ragged flower must pass in its advancement to the standard marked out for it by the florist. *Viola cornuta* in its varieties *alba*, *Perfection*, *Enchantress*, *Magnificent*, *Mauve Queen*, *Blue Bell*, &c., all exhibit improvements on the original. In Lothair, though we have the habit of *V. cornuta*, the flowers are clearly those of a Pansy. *Viola lutea* progressively advanced to size in *V. lutea grandiflora* and major, when all at once a clear leap was made from a Viola to a Pansy in *Crown Jewel*; though the habit of the plants be dense and robust, only a step or two of further progress is needed and the Violas may be included in the category of bedding Pansies.

It is questionable, however, whether Violas having Pansy flowers are calculated to be as effective for bedding purposes as those with smaller and more numerous flowers; for it is as well to bear in mind that if the size of the flower be doubled we have but one flower in the place of two, and this, though it may not affect the plant singly, does materially lessen its effect in a mass intended to represent a decided hue of colour. I confess to a liking for a good verdant ground with the flowers nestling in distinct masses of decided colour above it. But in the larger improved flowers the foliage is more ample, the flower having superior form enhancing its individual beauty. The size and form of flowers give a greater fitness for effective display than numerous small ill-shaped flowers, and I hail with delight the improvement which is being effected in this family of plants.

Violas to bloom well over a lengthened period require a rich and moist soil, not necessarily wet, but one which will support the plants in dry weather. Even a light well-drained soil, rich in humus by liberal dressings of manure and leaf soil, will give stamina to plants in dry weather, enabling them to withstand its effects with better results than are produced from plants in a heavier-textured soil. Violas, it must be borne in mind, are not marsh plants; they grow on knolls, or slopes, or in ground free from stagnant water: therefore, though a moist soil be desirable, it should be well drained, moisture being afforded by supplies of water in a prolonged dry period. Ground for Violas ought to be trenched or stirred to a depth of 15 to 18 inches or so deep, as good soil admits. It is no use going down with a view of bringing to the surface matter which, before it can be available as food for plants, requires amelioration by atmospheric influence and an addition of organic substance. Trench the ground in autumn, putting in some partially decayed vegetable refuse not further from the surface than a

foot; and if the ground will not admit of being turned up deeper loosen the under strata, placing the manure upon it, throwing the surface rough for the winter. In spring dress the surface with leaf soil or well-decayed manure, and dig with a fork, mixing the manurial matter well in the soil.

Plants raised from seed grow more upright and do not branch nearly so well, and are not, for a time at least, so floriferous as are those from cuttings. Seedlings are not good the first year; it is not until the plants are cut down that dependance can be placed upon seedling plants for a full display: hence I do not advise the plants to be raised from seed except for the origination of improved varieties. Those, however, who wish to raise plants from seed may sow the seed the middle of August up to early September in light rich soil in a sheltered situation, pricking out the seedlings 3 inches apart in a sheltered spot in October, and planting them in March or early in April.

Cuttings give the best and most floriferous plants. Take the cuttings towards the end of September or first week in October. Choose for them a sheltered border—under a low wall or fence—and moderately rich soil, made fine and level, surfacing with a thin layer of sand. Let the cuttings be of the shoots which spring from the base of the plants, not using the exhausted flower shoots, and about  $2\frac{1}{2}$  to 3 inches long, pricking them in about half their length 2 inches apart, firming them well in, completing with a good watering. In a very bleak position the cuttings may be put-in in a frame and wintered in every respect like *Calceolarias*. Plant them out in spring before dry weather sets in, and in no case defer their planting until the usual time of bedding, for Violas and *Calceolarias* are not able to contend with drought if it comes upon them before their roots have obtained a good hold of the soil. Short duration of bloom and sudden collapse are due to late planting. If *Calceolarias* were planted where they are to bloom in April we should see less of their failure, and Violas so treated are enabled to withstand drought. Plants from cuttings made in early October will give an effective summer display, but not unfrequently Viola beds become seedy in autumn, as, indeed, all plants do that have been in a high state of perfection during the hot summer months. For a late or autumn bloom cuttings may be put-in in May or June, affording them shade. An amateur tells me (and I have seen) how to strike Violas and Pansies in summer—namely, put them in between the rows of early Potatoes where the cuttings are shaded from the sun, and lift the plants with balls the first showery weather after rooting, and plant them where they are required to bloom. For a spring display—or rather early summer, for it is not until May that Violas are in their beauty—the cuttings should be put in the second week in August, and be in their flowering quarters in October. An earlier bloom will be had by wintering the plants in frames, planting out during March. Potted and plunged in cocoa-nut refuse they stand well, and if in the open a top-dressing of the same material is of great assistance to the plants. Plants divided in October and then planted will afford a good early display.

Violas stand wet well, better perhaps than any other flowering bedding plants, and succeed in summer in high cold situations where more tender subjects do not have other than a starved appearance. Being moisture-loving plants they are benefited by a top-dressing in summer, for if mulching has the property of retaining heat in winter it possesses equally the power of retaining moisture in summer. Soak, therefore, Viola beds with water in dry weather before the soil becomes hard and cracked if heavy, or dusty if light, applying the water to the roots rather than overhead, and mulch with short manure, which will be hid by the foliage. Neater than manure and as good is cocoa-nut refuse, and if this is placed close up to the plants they will produce fresh shoots freely, which will root into the mulching.

To keep the plants in blooming order through the summer it is necessary to cut off the seed pods and to thin-out the old stems, thereby encouraging young growth; and this attended to before the plants are exhausted, frequently going over the beds, attending to them with water and weak liquid manure in dry weather, we shall find Violas continue blooming from early spring to late summer in as good a state of perfectiveness as most descriptions of flowering bedding plants. They have, like other plants, a season of bloom, and if flowering be continued beyond it fresh parts must replace the exhausted growths, just as young plants are needed to replace plants which are old and worn-out. Royal Blue is the finest blue Viola, and *Crown Jewel*, a clear pale yellow, surpasses any other of its colour.

There are fancies even in *Violas*. *Princess Teek* is pale mauve; *Lilacina*, bluish lilac, of fine form and substance; *Admiration*, deep blue violet, its eye rayed with purple, and large flowers, must be classed one of the finest; *Alpha*, bluish purple and yellow eye, large finely formed flowers; *Lothair*, indigo blue, its well-formed flowers having a slight dark blotch in the centre; *Purple Prince*, mulberry ground shaded purple, its yellow eye rayed with black and encircled with blue; and *Waverley*, violet shaded purple, yellow eye and white brow, combining size with good substance. These are a few of the best of the *Violas*, which as yet are more limited in colour than the *Pansies*.—G. ABBEY.

### FEATHERED HELPS IN GARDENS.

THE above heading occurs in the *Journal of Horticulture* for August 24th to an interesting article, with the signature attached of one from whose pen I am always glad to peruse the statements from time to time made on different subjects of natural history. I am sorry therefore to have to differ with "WILTSHIRE RECTOR" as regards bantams eating slugs, as I have tried my fowls with them over and over again, and found them an object of dislike; sea-gulls also refuse them as food, but both are fond of worms.

The sparrows of England and Ireland must be of a different race, as those birds in the green isle never look at caterpillars. I have gathered them and thrown them into a yard where sparrows frequented, and they left them untouched. Where I am living at present sparrows abound, and the caterpillars are a regular plague this year, the Cabbages in my own garden and those of my neighbours being destroyed completely, and no sparrow interfering. I have never seen the cuckoo in a garden, or heard of one eating caterpillars.

I should therefore be glad to have this subject ventilated, and a bird discovered which would rid us of these plagues—slugs and caterpillars. Ducks are most useful. I have hardly a slug in my present garden, and I attribute it to the number of ducks I have; but you cannot grow Strawberries and ducks.—TYRONE INCUMBENT.

### USEFUL APPLES.

No arguments are needed to show the value of early Apples, and I am glad to note that your correspondent, "A NORTHERN GARDENER," has advocated the free planting of sorts of established value. He has confined his remarks to dessert kinds, and has mentioned a trio of undoubted value, omitting, however, in my opinion, other kinds at least equally good. It is not my intention to supplement the short list which he has given by enumerating other varieties of dessert Apples, but I would rather remark on the value and importance of another type of Apples—I mean Apples for culinary purposes which are early, profitable, and good.

During the last few years an unusually large number of Apple trees have been planted. This is the result partly of noticing that even in fruitful years the supply of Apples has not been too great for the demand, and partly the encouragement that has been given to planters by the supply of trees which the nurserymen have provided of a dwarf-growing early-bearing character by their having been grafted on precocious stocks.

It is only natural that a general hesitancy should exist in the minds of many who have land at their disposal, and especially in the case of those holding it under yearly tenancies, as to planting fruit trees which require many years to bring them into a profitable fruit-bearing state. It is not to be expected that people will occupy their land with crops from which they cannot derive, not only profit, but early profit. If they invest their money in fruit trees they require good and speedy interest in the return of fruit. In the old-fashioned orchard trees, and especially in some sorts of them, it is only by long and dreary waiting that large crops can be gathered and the money that has been invested be "turned over again." It is probable that when such trees do arrive at a bearing state that they are the most profitable of all trees; but we live in an express-train-and-telegraph age, when "time" is emphatically regarded as "money," and few, therefore, care to wait a generation for fruit, and it is only here and there one who studies posterity. But when trees were produced laden with Apples at three years from the graft undoubtedly a great impetus was given to fruit-tree planting, and many planted freely with bright visions of fortune urging them on, and pleasant

dreams of prosperity "whiling away the time" of waiting for the crops.

In not a few cases these profitable anticipations have been realised, but in many more, and perhaps the majority, the hoped-for reward has ended in disappointment. This has followed not so much through selecting bad sorts as by including in a given list too many varieties. It is generally the case when a person becomes an enthusiast in fruit-growing that he cannot rest until he has all the kinds which the authorities have invested with a reputation. When the grower grows fruit for pleasure primarily, cash profits being a secondary matter, nothing can be urged against that plan of procedure; but when profit becomes of paramount moment, and the tastes of others as purchasers of his fruit have to be considered, then no greater error can be made than in growing all the sorts of Apples to which are attached "good characters." In the cases of failures occurring blame is almost invariably thrown by the planter on the dealer who supplied the trees, or at least to some "person or persons unknown" who provided the estimates of their merits. In reality, however, the planter has only himself to blame. All the sorts that are recommended are good for some purpose, but the great question for each individual to ask himself and determine is, "Which varieties are best suited for my purpose?" That is a question of the utmost importance, and cannot be decided without much consideration, probably some advice, and especially extensive and attentive personal observation.

In contemplating the extensive planting of fruit trees two distinct questions are presented at the outset. Firstly, Am I planting for myself and my family—in fact for home use? and secondly, Am I planting for others—i.e., with the object of selling the fruit? To the first question I do not at present think it necessary to give any consideration, but propose to discuss the matter of Apple cultivation in its useful and profitable phases.

After some experience in fruit-growing, embracing both successes and failures, I have become convinced that it is not only advisable to have trees of a nature that commence bearing early, but the sorts must also be early ripeners. I am considering now the best way of "turning money quickly" by the cultivation of Apples. It so happens that the culinary Apples which are the first ready for use are kinds which are early and constant bearers. Late Apples are, weight for weight, more valuable than early Apples, but the trees of the latter do not arrive at a bearing state so soon as the former, and in the case of late sorts a margin must always be allowed for waste, and there is also some expense involved in preparations for keeping them. As to the relative period at which early and late Apples become profitable I will for comparison take the best early and best late culinary Apples, and note their characteristics. I will consider Lord Suffield the best early Apple, and Dumelow's Seedling the best late Apple. Both are excellent in their season, and are free bearers. I do not say that at the end of half a century that a hundred trees of the former would be as profitable as the same number of trees of the latter, but I do assert that trees of Lord Suffield will pay for themselves, and the ground which they are growing upon, before trees of Dumelow's Seedling produce a lucrative crop.

On the ground of securing an early return upon outlay I am bound to advocate the adoption of early sorts. These are ready at a time when the public are "hungering" for them; and if at times they must be sold cheaply, the crops are generally so large as to render them profitable. If we glance at a large orchard of Apples, or if we look down the long lines of trees in a large nursery, we generally find trees of the early sorts the most heavily laden with fruit. In the matter of young trees that may be said to be invariably the case. In seeking for early return, therefore, we must look to early sorts, sorts which are in a marketable state at the earliest possible moment, and which are sufficiently productive as to—even when Apples are cheap—render their cultivation profitable.

Probably the Apple which for a number of years has been the most useful and profitable in cottagers' gardens—and there profit is estimated at its real worth—is the Keswick Codlin. This favourite old Apple has done good service, and must not be lightly set aside—indeed, for orchard trees it is probably the best of all early culinary Apples; but for early fruiting dwarf-growing bush or pyramid trees it is superseded by Lord Suffield. This last-named Apple for early use is exceedingly valuable, and fruit of a saleable size is ready sooner than that of any other kind that I am acquainted with. It is also a prodigious bearer; it is, in fact, a large edition of Keswick

Codlin, possessing all the good qualities of that variety from which it was probably a sport. It is not quite suited for standard trees owing to the liability of the large fruits being blown off by the winds; but for dwarf trees on the Paradise stock it is one of the most valuable and useful of all culinary Apples; it should be planted freely by all coveting early fruit and a quick return on the outlay invested in trees.

I have for some years grown another Apple, which is superior to the Keswick Codlin, which is called Domino. It is larger than the Keswick Codlin, but not so large as Lord Suffield, but is of a deeper green than either, and is a prodigious bearer. It may only be a local Apple, but is largely grown in the midland counties, and is there known as one of the best. It is rapidly rising in public estimation, and may be planted with confidence of yielding an early and profitable return of fruit.

I consider that I have now mentioned the very best of the most useful of very early Apples, unless I add to them Duchesse of Oldenburgh. This Apple I am informed is of Russian origin. It is not quite so early as the sorts named, but it is a valuable successor of them. The tree is an early and great bearer, and the quality of the fruit is of a high order. It is also a very "taking" Apple in the markets by its rich stripes and attractive bloom. Another property it possesses which was pointed out to me by my lamented friend the late Mr. J. R. Pearson, is that it does not show its bruises. In speaking favourably to Mr. Pearson of Cellini he added, "Yes, Cellini is a good bearer and useful at home, but who would grow Cellini for market that knew the value of the Duchesse of Oldenburgh?" Duchesse of Oldenburgh is no doubt one of the best travelling Apples, and when we add to that its earliness, its productiveness and excellence, we have a combination of qualities rendering it valuable and a desirable sort for planting. The above Apples are tolerably well known, so that it is not necessary to submit a sketch of them; indeed, the best of them are "gathered and gone," and I have not a good sample of any of them left.

I will now advance a step further in the season of ripening, and draw attention to a valuable Apple which is not sufficiently known and cultivated, I mean the Ecklinville Seedling (fig. 26). I submit a section of this Apple, which will sufficiently show its size and form, and I will only add that it is handsome and excellent. The tree is an early and great bearer, and the fruit is in use from October to the end of the year. It is a very hardy Apple, and is suitable for standards on the Crab stock and for bushes on the Paradise stock. On the latter it bears when the trees are in quite a small state, and from my experience of it I believe it to be a variety worthy of extensive cultivation. I am informed that it was raised in Scotland, and that it is extensively grown in North Britain, and I know that it flourishes well in the midland counties and the south of England.—A MIDLAND FRUIT-GROWER.

### "THE NINETY AND NINE."

THE number is venerable, but I cannot make out ninety and nine of Hybrid Perpetuals which are perfect, so I must be forgiven if I intrude upon other classes to make up the number—the eclectic number! I will begin with a few old friends, some of which I have had from the year 1852 down to the present time; and how nobly have those old friends withstood the "tyrannic sway of time!" and how bravely have they met the most tyrannic winter, spring, and torrid summer! I will begin with our oldest Rose—one that seldom dies, and never will need an epitaph.

I do not place the sorts in the order of merit. Baronne

Prévost (Laffay), the oldest. William Griffiths. Gloire de Dijon. La Ville de St. Denis, not yet beaten. Madame Knorr, one of the sweetest and one of the most beautiful in bud. Caroline de Sansal, the hardiest of all the light Roses. Souvenir de la Malmaison, the finest of all the light Roses, but best as an autumnal Rose. Souvenir de la Reine d'Angleterre, a fine autumnal bloomer. Madame Louise Carique, the best lofty red pole Rose. When my friends, Mr. Sturt (now Lord Arlington) and Earl Walden, came here three years ago they greatly admired this Rose, planted like a leech bite (threes) between Cedars and Conifers and Deodars. "Ah!" said they, "that is the prettiest sight I ever saw!" Forgive me if I say that garden ornamentation is too much neglected. Anna Alexieff, a fine masser. Duchesse de Cambacères, rough in aspect, but excellent early and late. She throws her corollaries over her main blooms. Comte de Nanteuil. Duchesse d'Orleans, wonderfully fine. Madame Boll, extra fine, and beautifully scented. Acidalie, very fine. Baron Gonella, distinct. Sir Joseph Paxton, one of the finest of the corymbed Roses: add Triomphe de Rennes and you have the two best as corymbed Roses. Triomphe de Paris, very fine. Monsieur de Montigny, extra. Lafontaine, extra. Maréchal Vaillant, extra. Alexandrine Bachmeteff, after twenty years' wear she

is 8 feet high. The above are my oldest Roses, and I cannot but venerate them as outliving so many choice Roses and defying "Time's tyrannic sway."

I have hitherto mentioned some of our oldest Roses; I now mention some of more recent origin. Abel Grand, Achille Gonod, Baronne Adolphe de Rothschild, Felix Genaro, Baron Chaurand, this and Van Houtte are the finest-scented of the Hybrid Perpetuals. Black Prince, Charles Lefebvre, Claude Levet, Comtesse de Chabillant, Devienne-Lamy, Dr. Andry, Duc de Cazes, Duchesse de Caylus, Duke of Edinburgh, the most brilliant of all Roses. Edouard Morren, magnificent.

Elie Morel, a pale Baronne Prévost. Triomphe d'Alençon, a red Baronne Prévost. Lord Clyde. Lord Macaulay, most beautiful, but not a strong grower. Louis Van Houtte (Lacharme). I have the other. This and Maréchal Niel are the two finest autumnals, but somewhat delicate. Madame Alice Dureau, one of the best of the La Reine family; the most beautiful but the most delicate of the family is Louise Peyronny, *alias* Lælia. It is still the most beautiful in the line of rose colour. Madame C. Crapelet, Madame C. Wood, Madame C. Joigneaux, one of the best in the Rose kingdom, and finely scented. Mlle. Emile Boyan, a Perpetual Madeline. Lady Suffield, a real beauty. Madame George Schwartz, Madame Julie Daran, Baroness de Rothschild, Madame Creyton, Duke of Wellington, Madame Lacharme, small but most lovely. Mrs. Rivers, Madame Vidot, these two are still the finest in the light line. Madame Victor Verdier, Sénateur Vaisse, Mlle. Annie Wood, not autumnal. Mlle. Marie Rady, A1. Mlle. Thérèse Levet. Marguerite de St. Amand, a wonderfully good Rose. Marquise de Castellane, fine. Countess of Oxford, extra. Etienne Levet, extra fine, but scentless. Maurice Bernardin, one of the best. Paul Neron, large and fine. Pierre Notting, A1. Pierre Seletzski, one of the best novelties. Vicomtesse de Vezins, a fine grower, hardy, and excellent. Monsieur Woolfield, Prince Camille de Rohan, Prince de Portia, Princess Mary of Cambridge, Dr. Jamain, most beautiful. Souvenir de W. Wood, most beautiful. Monsieur Boncenne, Solfaterre, for a wall. Vicomte Vigier, Thyra Hammerick, Maxime de la Rocheterie, Gloire de Ducher, Baronne de Maynard, Leopold Premier, Dr. Andry, Madame Chirard, Triomphe de Rennes, Céline Forestier, Solfaterre, for wall only. Rêve d'Or, for wall, but must not be cut back.

Teas.—Devoniensis, Souvenir d'Elise Vardon, Madame

Fig. 26.—Ecklinville Seedling.

Willermoz, Souvenir d'un Ami, Adam, Duchess of Edinburgh, apparently a China Rose; Sombreuil, a wonderfully hardy Rose—a China Rose, I think; and Madame Margottin, a citron yellow.—W. F. RADCLIFFE, *Okeford Fitzpaine*.

### VINES LOSING THEIR LEAVES PREMATURELY.

THREE years ago I planted a house of young Vines, which made satisfactory growth the first season, and the second year the canes were exceedingly strong, leading me to expect correspondingly large bunches; but in August, 1875, they cast their main leaves, and the bunches this year while good are not so large as I anticipated. This year the wood is very strong and the foliage again shows signs of dropping. What is the cause? "Dryness at the root," says one visitor, but I know that cannot be the case; while another suggests that the "glass may be at fault;" and a third a "dry atmosphere" is the cause of the grievance. Now I do not concur in any of these solutions of the difficulty, but I attribute the defoliation to the innate vigour of the Vines, and that the rapid swelling of the canes is the cause of the leaves being pushed off. I am led to this conclusion by the fact that the leaves on the moderate-sized canes are green and healthy. I shall be glad to have the opinions of other growers on this matter, as I fear there is a tendency to err in inducing an excessive grossness of growth in the anxiety to obtain gigantic bunches. I have observed in the case of Vines of this character that when the bunches have been of considerable size the berries have not been correspondingly large and well-finished. My experience leads me to prefer moderately strong wood which retains the foliage until late in the autumn, when bold eyes are perfected and good Grapes follow. It is seldom that well-cultivated Vines in pots cast their foliage so soon as the stronger canes, the roots producing which have the unrestricted freedom of a rich border.—W. J. B.

[The views of our correspondent are precisely in accord with those of Mr. David Thomson, who, replying to the question, "Why do young vigorous Vines frequently lose their main leaves prematurely?" writes as follows in "The Gardener":—

"This is an affection, or rather misfortune, which in the case of young growing Vines perplexes and, to a certain extent, alarms some growers, causing them to be apprehensive that some disease has overtaken them. The occurrence is most frequent in the second year's growth of young vigorous Vines; the more rapid and vigorous their growth the more leaves they lose in this way. We were long puzzled as to the cause of young Vines suddenly, and in the very zenith of their growth, losing so many leaves, but are quite satisfied as to the cause, which is purely mechanical. When such young Vines are stopped, either before they get or just as they reach to the top of the house, they then begin to thicken with great rapidity, even to the rending of their bark in many cases, and their circumference at the nodes, or the place where the base of the large leaves is fixed to the stem, increases more rapidly than the base of the leaf grows, and so the union of the leaf with the stem is rent or ruptured, the sap into the leaf checked, and the power of the sun acting on the leaf causes it to collapse and wither, and it soon loses its hold of the stem altogether and falls off, while the leaves on the lateral growth which proceeds from their axil grow on fresh and green. This mechanical occurrence can be easily detected with a magnifier, and is most conspicuous, of course, during bright weather. The Vine no doubt suffers slightly from the loss, but not materially."]

**GODETIA LADY ALBEMARLE.**—When looking over Messrs. Daniels Brothers' seed farm at Norwich I was highly pleased by seeing their new *Godetia Lady Albemarle*, it was such a glorious mass of rich shining colour. Since then it has been exhibited in London, and has received a first-class certificate from the Royal Horticultural Society; but to see a few plants or a boxful of it unexposed to the sun gives little idea of its splendour. Though it remains open night and day, to form any notion of its effect it should be seen in a mass with the sun shining on its large glossy flowers, few of which are less than 3 inches across, and entirely different in effect to anything usually seen in the open garden. The flowers are not unlike those of *Dipladenia crassinoda*, with the rich crimson shade of the newer varieties, but far exceeding these in the richest silky appearance, and of so beautiful a colour, too, at a time when many of the best annuals were burnt up with drought.

Not one annual or bedding plant can compare with it in producing such a mass of dwarf, dense, compact plants, the foliage being entirely covered with flowers.—THOS. STAFFORD.

### THE "SLEEP OF PLANTS" AS AN AGENT IN SELF-FERTILISATION.

At a recent meeting at the Academy of Natural Sciences of Philadelphia Mr. Thomas Meehan said that what is popularly known as the "sleep of plants," the closing of some kinds of flowers at nightfall, though a matter within common observation, had not, so far as he was aware, been made a subject of physiological investigation with the view of ascertaining the value, if any, of this kind of motion in the economy of plant life. He had recently discovered that by means of this peculiar motion the common *Claytonia virginica* and some Buttercups were fertilised by their own pollen. The fertilisation of these plants had been somewhat of a mystery to him, as, in view of some prevailing theories of cross-fertilisation by insect agency, these plants ought not to be self-fertilisers, but from repeated observation he was satisfied that no insects had visited plants that had yet seeded abundantly. Watching the process of fertilisation in *Claytonia*, he found the stamens on expanding fell back on the petals expanded during daylight. At night, when the flower closed, the petals drew the anthers up in close contact with the pistils. Cross-fertilisation could be accomplished by insects if they visited the flower, but they did not; and actual fertilisation only occurred in this way. In many cases, especially in the advance of the season, the stamens recurve so much as to be in a measure doubled-up by the nocturnal motion of the petals. The anthers were not drawn into contact with the stigmas in these cases, and the flowers were barren as the result.

In the *Ranunculus bulbosus*, our common Buttercup, in the evening following the first day's expansion of the young flower, the immature anthers and the young stigmas would be found covered with pollen grains. The inference would generally be that this had been carried there by insects. But as he had been especially on the look-out for insects as visitors to the Buttercup, and feeling sure that none of any consequence had been to them, he examined these flowers carefully, and found that on the first expansion of the flower a single outer series of stamens burst their anther cells simultaneously with the expansion of the flower, and, by contracting the cell walls, ejected the pollen to the smooth petals, from which it easily fell to the immature anthers and stigmas when the flower closed for the night.

Knowing that another species of Buttercup, the *Ranunculus abortivus*, had fixed spreading petals which did not close at night, and which, though with comparatively large nectariferous glands full of a liquid secretion, was wholly neglected by insects, and yet had every flower seeding profusely, he was anxious to find, in view of his other discoveries, how these were fertilised. Visiting a wood after twilight to ascertain if any nocturnal insects visited them, he found that though the petals did not close at sundown, the slender pedicels drooped, inverting the flower, and in this way the pollen found its way from the petals to the stigmas without any difficulty whatever.

Plants, of course, had peculiar functions to perform, and there were pre-ordained plans and special arrangements through which these functions are exercised. But the workings of plant life are so complicated that, though we see certain results follow certain movements, we are not always sure that we perceive the great and deeper object aimed at in the order of Nature: hence arose the differences of opinion prevailing in regard to the object of cross-fertilisation. Some plants had arrangements which seemed to preclude the possibility of self-fertilisation, and the assumption followed that Nature abhorred close breeding in plants, and specially designed such structures to secure the plant against it. He believed that Nature had a deeper purpose as yet unknown, and chiefly because of such instances as he had given, where Nature could not abhor close breeding when the result of the "sleep of plants" was most perfect in securing self-fertilisation.

### DIOSPYROS KAKI.

I CAN answer some of "G. S.'s" questions as to *Diospyros Kaki* (page 193). We have a small compact plant in the orchard house with ten fruit. The fruit was exhibited before the Royal Horticultural Society's Fruit Committee from Sir W. Hutt's garden, but I do not remember having tasted it.

The plant is pretty even with its green fruit. When this is ripe and has the orange colour it should be very ornamental. A friend who knew the fruit well in Japan told me that it is considered good there. He cautioned me against allowing an overcrop, as the fruit in that case falls. I therefore thinned our plant.—GEORGE F. WILSON.

[The fruit received is 2 inches in diameter, and somewhat resembles an unripe Tomato, being green and slightly ribbed, but is more solid than a Tomato. When ripe it must be highly ornamental. We shall be glad to hear further from Mr. Wilson when he has proved the quality of the fruit.—Eps.]

### THE DOVER FLOWER SHOW.

"WHAT! you here!" was the exclamation of one of "those most potent, grave, and reverend seigneurs" who rule the destinies of our Journal when I met him in the Priory grounds, where the Committee of the Dover Horticultural Society had arranged their Show. The next word was more *sotto voce*—"I look to you, then, to tell us something about it." What could I do but obey? and hence this short report.

There was something pleasant and picturesque in the appearance of the grounds and the old refectory where the Show was held; and although the day had been unpromising the rain held off and bright sunshine added its charms to the scene. The plants were arranged in the refectory, where also the fruit and table decorations were displayed, and a much worse place could not possibly be for showing off the beauty of the exhibits. The light was of the faintest character, and the gloomy aspect of the walls added nothing certainly to their appearance. Nor were the plants of any great moment. At this season of the year it is a difficulty to get together stove and greenhouse plants; and as there are no persons in the neighbourhood who go in for exhibiting, those shown were simply such as may be found in any gentleman's garden of any pretensions—very unlike what one sees at such shows as Taunton, Spalding, &c. The gardeners of Sir Henry Tufton, Sir Walter James, S. Ashley Dodd, Esq., and others exhibited plants of fair average quality but in no way remarkable. In this part of the Exhibition the greatest interest was excited by the table decorations, &c., for which there was a spirited competition. The classes were for a stand of wild flowers and grasses, dinner-table stand of fruit and flowers, and basket or vase for the dining-room. The first prize in the class for wild flowers was adjudged to Miss Tompkin, Buckland Vicarage, for an exceedingly pretty and well-arranged stand. The dinner-table stands were for fruit and flowers—an unsuitable arrangement which has been long since discarded in most places. It gives a lumpishness to the stand which utterly destroys its effect; and, moreover, the fruit is placed inappropriately. If it is not to be eaten its place would be better supplied with flowers; and if it is, the appearance of the stand would be destroyed by its removal. The first prize was awarded to Mrs. R. H. Jones: it was far too full, and it would have been utterly impossible for anyone to have seen those opposite to them through its dense groups. Miss Kingsford was second; and the same remark applies, for the stand had a number of cornucopias which were too full of flowers. The third-prize had a bunch of Grapes suspended in a tripod—very inelegant. In the class for drawing-room baskets or vases some really pretty groups were put up, the first prize being adjudged to an exceedingly well-arranged group by Miss Kingsford of Woodside. Unfortunately another competitor, whose stand was of equal merit, was disqualified owing to the exhibitor misunderstanding the schedule and placing some trays round it.

As usual in these autumnal shows the chief points of attraction are the cut flowers, and of these there was a very good display. The Gladioli were unhappily placed. During the early part of the afternoon the sun shone through the canvas of the tent, completely killing the colour of some of the more delicately coloured flowers. They were exhibited by Mr. Banks of Shobden, our largest amateur grower; Dr. Scott of Sandcombe, Messrs. Bunyard & Son of Ashford, and "D., Deal." In addition to the very flattering notice of "G." in last week I have a word to say on a matter connected with them of which I am not a little proud, and have written a separate notice detailing it. But few of this year were exhibited. Hecla was shown well, and there were two or three fine blooms of Le Vesuve. Giganteus was good in Mr. Banks's stand, and Ginevra and Murillo were excellent, so also was Leda. Mr. Banks exhibited a number of good seedlings, amongst them a remarkably fine white flower of great size and substance. The long array of stands occupied a considerable space, and greatly attracted the attention of visitors.

The cool weather of the last ten days had materially assisted the Roses, which were shown in very fair condition for this season of the year, Messrs. Bunyard & Son exhibiting a very good box of twenty-six. Asters were not, as might have been expected, as good as usual. Dahlias were but poorly represented, but there were some fine boxes of cut flowers of Geraniums.

The dry weather had told against vegetables, as might have

been supposed, and really the wonder was that Carrots and Onions could have been exhibited in such condition as they were. It was in the class for cottagers that the effects of the season were especially felt, as they, of course, have not the means and appliances for combating the effects of a bad season that there are in large gardens.

Knowing as I do how little hold horticulture has in East Kent I can safely say that the Exhibition was creditable to all who were engaged in organising it, and a more efficient and courteous body of officials it would be difficult to find.—D., Deal.

### THE DEVON AND EXETER AUTUMN SHOW.

THE Exhibition held at Northnhay on the 1st inst. was not large, yet, in some points, noteworthy. The Committee were unable to offer large prizes for nurserymen, so the grand exhibition of stove and greenhouse plants, which have been one of the great attractions of former shows, were conspicuous by their absence; but notwithstanding a small tent was filled with some fine specimens from the glass houses of Messrs. Locombe and Pince and Mr. H. Sclater. Dr. Woodman, the fortunate owner of the former establishment, very kindly sent some of his finest plants. His collection of Allamandas was fine, and he showed a grand plant of *Rondeletia speciosa* major. His *Ixoras* were also fine specimens, but his *Crotons* were simply wonderful, particularly *Croton variegatum*, which I believe is considered the finest plant in England. One Fern electrified me; it was *Davallia Mooreana*, and this I was assured by one who ought to know is considered the finest specimen in the world.

As it happened the tent set apart for these exhibits was far too small, whilst the one erected for table decorations was exactly *vice versa*. Very few entered for these good prizes, and indeed for the amateurs' class for three vases of fruit and flowers only one lady put in an appearance. The Judges had a very difficult task to decide on the other exhibits in this section. These were uncommonly good, particularly one put up by Sir T. Acland's gardener. He was placed second, but he lost the first prize by having his centre vase considerably lower than the two others. Here explained afterwards that he was unable to procure a taller one, which was a great pity, as the centre vase was the best I have seen for a long time. The base consisted of *Bougainvilleas*, Ferns, grasses, and fruit, with a lovely bloom of *Lælia purpurata*. Up the stem of the glass a climbing plant was twined, and the dish itself contained a Pine Apple, which was surrounded with blooms of *Eucharis amazonica* and Maidenhair Ferns. In one of the other vases he had the finest bloom of *Souvenir de Malmaison* Rose which I have ever seen.

The feature of the Show, however, was the stand of Gladioli staged by Messrs. Kelway of Langport. The perfection to which this flower has attained is simply wonderful, and every year fresh beauties are produced. Three first-class certificates were awarded to seedlings. One named Dr. Woodman is a splendid variety, the colour being a rich salmon, flaked with pink and lake; the petals being of enormous size. Another, named Earl of Mount Edgumbe, is rose colour and flaked with white; while the third, which excited the admiration of everyone, is of the richest creamy white, with a dash of violet in it; the petals were flaked, or rather pencilled, with faint lines of pink or lake. This Gladiolus was named after a friend of mine, who has had a Rose named after him, and is described as being of a globular form and of a bright rosy pink complexion. Some of the most noteworthy of the other Gladioli were Adolphe Brogniart, W. Thornton West, pink and white; Lady Bridport, flesh colour, flaked with rose; Libo, ecclesiastical red; Henon, Marian, W. Cotton, and Coutha.

The show of Dahlias, Roses, and Hollyhocks was small, but one or two very fine blooms were to be found in Mr. Beachey's stand of Roses; notably *Souvenir d'Elise*, which was one of the finest I have seen this year.—WYLD SAVAGE.

### CHAPTERS ON INSECTS FOR GARDENERS.

No. 11.

THERE has been some joking with regard to the speculations of certain philosophers, who have maintained that they could greatly improve upon Nature had they the opportunity. Thus, could they re-adjust matters, they think it would be much better that Pumpkins and Melons should grow upon large trees, and Nuts or Apples upon low plants only, which would harmonise with their notions of æsthetic fitness. Some horticulturists may possibly be inclined to theorise rather in the same direction, and an illustration is afforded by the economy of the aphid tribe. Few are now ignorant of the fact that these insects have an excessive power of multiplication, since the females in a mode that ought to be highly agreeable to the advocates of women's rights, who are apt to seek arguments and illustrations from all sorts of sources, produce generation after generation of "fat and fair" aphides with sur-

prising rapidity in the summer season, utterly contemning the absence of the masculines of the race, a small array of which appear towards the end of autumn. Without these, however, it is assumed the deposition of eggs would not occur, and it is in the egg state that the bulk of the aphid families pass through the dreary season, though a few rather tough long-lived individuals struggle on from autumn to spring in sheltered spots if the gardeners will leave them alone. Well, not to be prolix, had we been asked to arrange the details of entomological life, it is possible we should have decided that aphides had better not be quite so prolific, and we might have transferred this capacity of breeding to some species that are beautiful and not injurious. But we may as well reconcile our minds to matters as they are, and perhaps after all there is some sense in the consolation offered by one naturalist, who asserts that many of these seeming pests serve to indicate plants that are weakly, or which require looking after. It may be allowable here to put emphasis on a remark which is not original, that in destroying aphides a random proceeding may even be productive of more harm than good. I will not say anything against syringing and fumigating, though these kill frequently both the aphides and the parasites that prey upon them; but I will give an instance in the case of hand-picking. In a Hop plantation this summer, on some of the lower leaves of the bine there were numerous aphides, and thickly interspersed among these the eggs of one or more species of *Coccinella*. To have removed the leaves indiscriminately and burned them, as many persons would have done in such a case if they did anything, would have been to destroy friends with foes, and it was thought better even at some outlay of labour, to go from leaf to leaf crushing the aphides but leaving uninjured the eggs of their devourers.

Now, the aphides which appear so numerously both on cultivated and uncultivated plants, scarcely a species being entirely free from these pests, may be at once separated, if not on strictly scientific principles yet very naturally, into two great divisions. To the first belong the aphides that feed exposed or only concealed by the bodies of their relatives (for it is observable that there is sometimes a double layer of these insects); to the second belong those that are partly or entirely hidden from view, either by their own exudations or by their habit of contorting the leaves and stems of plants, of burrowing in their roots, or in some way causing an unnatural growth. These mischief-workers in secret are most annoying to the gardener, for they necessarily escape various bird and insect enemies. Rain does not materially affect them, and their ravages are often unobserved until it is too late. It is amusing to notice, however, the diligent manner in which the ants will hunt-up the hidden aphides, often thereby intimating to the observer the fact of the presence of these destroyers of plant vitality. It has been suggested, though it is hardly capable of proof, that the aphides which by their operations so greatly disfigure some plants and shrubs, or even trees, must in some way poison or injuriously affect the species they frequent, otherwise the results would not be as we find them. Among the gall-producing insects of the Hymenopterous order, it is certain there are some that by their punctures set up an unhealthy action, ending in morbid growths. But with the aphides it is more likely that all the evil they do arises from the exhaustion they cause by their rapid suction of the sap; perhaps the immense number of small punctures a party of them make may cause a sort of irritative action, leading to the odd twists and contortions of aphid-haunted shoots. The most singular locality for aphides, to my thinking, is within the roots of plants, where swarms of them are now and then discovered. Possibly they may be more plentiful in these situations than we should imagine were they always identified, but few persons would expect to discover aphides in roots: hence, from their small size, they are overlooked. We might ask several questions about these not easily answered, and wonder if they have winged representatives, or if they perform migrations like the rest of the brethren, or if they first became feeders upon roots, because their ancestors were carried under ground and kept prisoners in ant hills, for it is the habit of ants, as is well known, to make captives of their aphid favourites, their "milch kine," as the aphides have been facetiously called. Though it is almost as odd that aphides should cluster in the interior of an Apple as in a root or bulb, for Mr. Newman records the discovery of that fact as far back as 1835. "I have," he says, "cut open Codlin after Codlin and found the pips garrisoned with them; not one lone aphid, but a whole troop of all sizes. When I let in the daylight there was a consider-

able sprawling and waving of legs, and no small alarm in the hive, but by degrees they got used to light and fresh air, and were quite still. I tried to tickle them with a straw in order again to watch their movements, when, lo and behold, they were all dead—gathered to their fathers; gone to the tomb of all the Capulets! Some had heaved anchor and dropped from the pip; others, fixed more firmly, had died at their posts, and, tucking their legs together under them, hung by their beaks." 'Twas an extraordinary circumstance that they should die on contact with the air, indicating clearly that they could never have worked their way from the outer world into the Apple; and as the point has not been made out by research we can only construct a theory on it, assuming that the eggs must be deposited outside the Apple while it is yet juvenile, and that the young aphides burrow in. This would show a different habit to that prevalent amongst the majority, where, as I have noted, eggs are only laid in the winter.

If we "collar" the first aphid we catch upon our coat-sleeve, or pick off one off our Geraniums, and subject it to a slight examination (should it be a tolerably plump one we shall not require a magnifier to help us), we perceive that the oval body is supported by six slender legs, and at the extremity of the body project two short knobs, which are tube-like. The insect tucks its head under, so that we do not readily see the proboscis or sucking apparatus, though the long antennæ which adorn the head are visible enough, and occasionally the eyes shine out when the general colour is pale. Should the aphid be in the winged state the difference in size between the fore wings and the hind wings is very perceptible; they are also held perpendicularly, not sloping over, as in the *Psyllidæ*. Ordinarily the motion of a crawling aphid is but tardy, though some species display more activity than others. As to colour—well, there is a great variety in this respect, and even in the same species the hue differs with the age and sex. Thus in the excessively common *Aphis Tiliæ* the female is pale yellow, the male yellow and black spotted. In the species which abounds on the common Elder the winged individuals are much darker than the wingless, although the latter may beat them in size on exact measurement. On the Elder, as also on neglected Roses and other plants, aphides will be so numerous at times as to form a double layer, and one naturalist ingeniously explains the reason of this, telling us that the upper layer is engaged in the continuance of the species, and that the lower layer is busy feeding. This is more clever than true, for on this idea of the arrangement all the old folks must be above and the young folks below if we suppose that those once above eat no more but die off after they have become parents. But so far as I have noticed, aphides large and small are commingled in both these layers, therefore I imagine that they shift about somehow and take turns at getting sips of the sap. And in this place it may be well just to advert to the question as to the early nourishment of the young aphides, since, on the one hand, it has been positively asserted that they draw their food at first from the maternal tubes, and, on the other, that this sweet secretion (called also by the name of honeydew) is only directly taken from the bodies of aphides by their faithful attendants the ants. If we were to accept the former statement, then, of course, a female aphid which has proved a parent of a goodly array of young ought to have them swarming about her just as the reader must have seen a broad-sided sow attended upon by her litter of pigs. This does not seem to be the case; the recently hatched aphides take their places orderly enough, but not in such positions towards their affectionate (?) parent as would lead us to surmise she is also nurse. Yet it may be that young aphides do occasionally devour the honeydew, as this food is attainable so easily, and is, indeed, only a very slight modification of the juices of the trees or plant on which it occurs. But I believe aphides, however juvenile they may be, are well able to shift for themselves and draw from the vegetable world direct the food that Nature impels them to seek.
